Inspection Report to Classification Societies.

The Rules for Electrical Installations, as stated above, have now been completed and are in the hands of the secretary to be passed on by the Board of Directors. These Rules will be published in pamphlet form and it is the intention that they be sold at a nominal figure.

Too much credit cannot be given to the various Members of the Ship Installation Committee and the Chairman, Mr. G. A. Pierce, in particular for the work accomplished, as we believe these rules to be the most complete and comprehensive ever formulated by any society, covering as they do practically every phase of the electrical field as applied to ship work and extending the field of the Institute to practical installations. This being an innovation on the part of the Institute, the attitude of the ship owners, builders and classification societies relative to their adoption is eagerly awaited. Several new features are also introduced, which will probably extend the field of this work to a marked degree.

The rules as now completed have been referred to the various classification societies and the emergency Fleet Corporation, all of which were given them opportunity to comment. This method of action has gone far to put in composite form the work as viewed from the different angles. When published, copies of the rules are to be forwarded to the Institute of Electrical Engineers of England, France and Italy.

As the work of the Ship Installation Sub-committee neared completion, it was found that, due to the magnitude of this work, it would be necessary to have someone care for the preparation of it, in order that it could be put in final form for publication. It was

therefore decided to appoint an Editing Committee, whose duty it would be to correlate the vast amount of information contained in these rules. The work of this committee was no easy task and we therefore take this opportunity of complimenting it on its labors in connection with this work.

The Marine Propulsion Committee has prepared its historical and data work and it is suggested that this be put in form to be published in the JOURNAL of the Institute, as a means of drawing out discussion and additional data as regards this subject. It was decided to await experience on electrically propelled ships, soon to be put in service, rather than introduce data based on theory only. It is suggested that this feature be given careful thought and consideration during the coming year, as many new ideas will probably result from the experience gained by that time.

Historical Committee

The Historical Sub-committee has prepared a Historical Review of the Use of Electricity on Shipboard. This review accompanies and forms a part of this report. A more complete account will be prepared for publication in the JOURNAL of the Institute. This is considered a very important work, as the evidences of the use of electricity in the marine field are only fragmentary and should be placed in a form of record, as a matter of history. When this is accomplished, it will then be a very simple matter to add, from time to time, the outstanding events in their chronological order. This historical feature is one that should not be lost sight of in the work of future committees.

In line with the requirements of the rules as now completed, governing the installation of electrical apparatus on merchant ships, it is suggested that next year's committee take up the matter of approval of various fixtures, fittings, etc., with the end in view of having these meet the requirements of the new rules. It is believed that the preparation of General Construction Specifications, covering various appliances should be performed by the Marine Committee.

One of the ideas brought forth during the year, was the consideration of terminal facilities at marine piers. This is more or less a new activity, as very little has been done thus far to facilitate the handling of cargoes at these terminals. The field is large and is therefore due a considerable amount of thought.

In conclusion, I feel that particular comment should be given to large attendance of the members of this committee at the regular meetings and the splendid spirit of co-operation existing between these various members. It is only in such harmony that the greater results, for which we all hope, are to be attained.

ARTHUR PARKER, *Chairman.*

HISTORICAL REVIEW OF THE USE OF ELECTRICITY ON SHIPBOARD

The marine field has probably been one of the most backward in the adoption and development of electrical apparatus which in the main, we believe has been due to the traditional conservatism of the seafaring man. While electricity was used to a very limited extent as far back as 1882 for interior communication, watertight bells, buzzers, annunciators, etc., having been installed by the Chas. Cory & Son Co. on the *Santa Rosa* about this time, and in the Navy electrical instruments were installed on the *Trenton* in 1883, apparently one of the first, if not the very first, electric light installations was also made on the *Trenton* about this time, at New York Navy Yard. All early lighting installations were Edison bipolar generators belt driven to an Armington-Sims or other reciprocating type engine. Voltmeters were not used until after the early '80s, and field regulation was not indulged in until about the same time, all of the early installations simply having a pilot light on the generator for gauging the voltage and candle power of the lamps.

Early wiring was installed in wood mouldings, and we believe that Habirshaw wire was considered the standard in the early installations, which was rubber covered with tape outside. Branches were in most cases spliced and the first junction branch boxes were used about 1885-1886. Fuses were used about the same time, usually using an ordinary single fuse placed in the branch circuit on a small insulating base which was inserted in the moulding.

The first marine telephones, we believe, were installed on the U. S. Cruiser *New York* (the first *New York*) about the year 1890. They were single direct circuits, *i. e.*, two telephones used in place of voice tubes. The instruments were of the "Bell" type and installed by Chas. Cory and Sons. The first "loud speaking" marine telephones were installed on the *Korea* and *Siberia* and the U. S. S. *Charlestown*, about 1895.

The first complete central energy (operator's) switchboard telephone systems were installed on the S. S. *Le Grande Duchesse* built at Newport News about the years 1897-1898. Pneumatic electric bells and annunciators were used quite extensively on ships during the period 1878-1890.

While the records are not clear we have every reason to believe that electric bells were installed in the Navy on ships at least ten years previous to the first electric light installation on the *Trenton*.

The most conspicuous example of the use and rapid development of electricity on shipboard has been in the American Navy, which has not only been for years a larger user of electrical machinery than the merchant marine, but also has led the navies of the world in this respect.

Lighting equipments were installed in the Navy on several of the early vessels, beginning with the *Trenton*, and certain power application installed, such as the ammunition hoists on the Cruiser *New York* and the Battleships *Massachusetts*, *Indiana* and *Oregon*, turret turning equipment on the Cruiser *Brooklyn*, and certain

minor auxiliaries such as ammunition hoists on the gun boats *Wilmington* and *Helena.* The extensive use of electrical apparatus for lighting and power purposes was not made however, until the Battleships *Kearsage* and *Kentucky* were constructed in 1898-1900, these vessels having seven 50-kw. engine-driven, 80-volts generating sets, which were operated in series on a 3-wire system to give 80 volts for lighting, and two voltages 80 and 160, for power motors. The major portion of the auxiliaries on these battleships were electrically operated, including the winches, boat cranes, ventilation fans, broadside ammunition hoists and turret auxiliaries. The anchor windlass and steering gear however, were steam driven.

After the *Kearsage* and *Kentucky* some succeeding battleships continued in many of their auxiliaries the use of steam drive, and the *Kearsage* and *Kentucky* are the only instances in the Navy of the use of the 3-wire control.

About 1902 the Navy Department devised an electric steering gear operated on the follow-up system and purchased apparatus of different manufacturers to effect installation on one of the small monitors which had then been recently constructed. The results obtained from this equipment were not satisfactory however. This question remained under discussion for a number of years until about 1909, when a contract was placed for supplying electric steering gear for the Cruiser *Des Moines* with the Cutler-Hammer Mfg. Co. For this purpose the use of an electric motor taking its power direct from the dynamo mains and operated by automatic controller was advocated. The results of this trial equipment were so satisfactory that it eventually resulted in the use of electricity for the steering of all capital vessels in the Navy, the later installations, beginning with the Battleship *New Mexico,* employing the use of the electro hydraulic gear instead of the direct motor drive, and to the exclusion of the steam drive.

Beginning with the Battleships *Nevada* and *Oklahoma,* electrical equipments were provided for the anchor hoist gear, which proved so generally satisfactory that all subsequent capital ships have specified electrical drive for this auxiliary, thus practically completing the application of electricity to all auxiliaries on capital naval vessels.

The use of electricity for lighting and auxiliary power purposes in the Navy having proved so generally successful, the General Electric Co. was granted contract for the installation of electric drive on the Collier *Jupiter* in 1911 which proving satisfactory, a contract was given to the same company for the installation of electric drive on the Battleship *New Mexico,* which continuing the satisfactory results obtained, all battleships and battle cruisers authorized since the *New Mexico* have included the electric drive, and undoubtedly it will remain the means of propelling capital ships of the Navy.

In the submarine branch of the Navy various means of supplying the necessary power for propulsion on early boats when submerged were used, such as hand power, compressed air, and steam. With the development however, of the storage battery, the application of electrical apparatus to the submarine made rapid advancement and made the modern type of submarine possible. In the modern submarine, besides using motors and storage batteries for propulsion purposes, all auxiliary machinery such as hydroplane, steering gear, pumps, windlasses, machine tools, periscope hoists, etc., are electrically operated, electricity also being used for lighting, sound detecting devices and interior communication devices of various kinds. The growth of electricity in the case of submarines may be noted from the fact that the early successful types were equipped only with electric lighting, bell signals and motors for propulsion under 50-h.p., whereas in the most recent electric propulsion, motor power has reached about 3000 h.p. As a matter of historical interest, the first application of the use of propulsion motors for submarines arranged with two armatures on the same shaft was made by the Lake Torpedo Boat Co. on submarines built in Russia for that Government and designed in 1906 and furnished with contactor type of controllers arranged for series parallel operation of the armatures as supplied by the Cutler-Hammer Mfg. Co., this type of motor and system of control being now extensively used in the later submarines of the American Navy.

The American Navy therefore, at the present time, is a user of electricity for practically all purposes for lighting and power and extensively for interior communication work.

While the American Navy has led all other navies of the world in the use of electricity, Europe seems to have led this country in the trial of electrical auxiliaries for use on merchant vessels, and while electricity has been used generally for lighting and some interior communication purposes on merchant vessels for years, it has been employed but to a very limited extent for power purposes until the advent of the oil-engine-driven ship, the most notable instances of this kind being the fleet of vessels constructed by Burmeister and Wain of Copenhagen, the *Christian X* being one of the first vessels so constructed by this company, and its first voyage to this country created marked attention. Since that time it is understood that some 70 or more vessels of this type have been constructed and projected by that Company.

In 1916 and '17 a number of merchant vessels were projected in this country, including tankers and cargo vessels employing electrical auxiliaries, among others being the Tanker *La Brea* with electric operated pumps and the Tanker *Solitaire* just completed by the Texas Co., having oil-engine drive and electrical auxiliaries throughout, including electric heating. Other instances are six tank vessels constructed by the Penn-

sylvania Shipbuilding Co. propelled by geared steam turbines and having electrical auxiliaries.

At the present time there are a number of oil-engine-driven cargo vessels with electric auxiliaries and others with electric drive and electric auxiliaries being projected in this country, and it is believed from this time the field will rapidly broaden until a great many of the merchant vessels will be so propelled and operated.

Extensive progress has been made recently in the merchant field in the use of the electric drive, the first installation on record in this country being two fire boats constructed in 1908 on the Great Lakes. Since these first installations in 1908, a total of 28 electrically propelled vessels have been constructed or projected, all but three of these being built or building in this country. Among these may be mentioned the four tankers constructed by the Pan American Petroleum Transport Co., the trawler *Mariner* equipped at the New London Ship and Engine Bldg. Co.'s works, the passenger ship *Cuba*, the 12 ships projected by the Shipping Board, and the cargo vessel *Wulsty Castle* constructed in England. This growing use of electric drive within the last two or three years would indicate a still further and more rapid adoption.

While the above gives a preliminary and general outline of the history and development of electricity on shipboard, a more complete and detailed historical review of this subject will be compiled during the coming year for submission to, and publication by, the Institute.

H. L. Hibbard

ANNUAL REPORT OF THE LIGHTING AND ILLUMINATION COMMITTEE

To the Board of Directors,

I BEG to submit on behalf of the Lighting and Illumination Committee the following report for the year 1919-20.

Activities of the Committee

Your Lighting and Illumination Committee, at its meeting on October 10th., 1919, decided to conduct a symposium on "Distribution Systems for Street Lighting" at one of the Institute meetings of the year, and to schedule, if possible, a paper on "An Analysis of Daylight Saving" at the Midwinter Convention. These plans resulted in holding the national meeting in Chicago on January 9th and 10th under the auspices of this Committee, at which three papers were read dealing with street lighting distribution systems. One of these papers on series systems was presented by W. P. Hurley, another, on multiple systems, by Ward Harrison, and a third, on constant potential series systems, by Charles P. Steinmetz.

The Chicago meeting was very successful and the discussions at both sessions were as complete as time permitted. At the afternoon session, prepared discussion was presented by C. H. Shepard of the Lincoln Park Board, Chicago; by N. B. Hinson, of the Southern California Edison Co.; by F. F. Fowle and W. F. Parker. In the evening, following Dr. Steinmetz's paper, illustrated discussion was presented by

F. A. Vaughn together with a description of the new group lighting system now used in Chicago for underground distribution for residence street lighting, by Deputy Commissioner Nixon. The newest things brought out in this discussion were the Chicago group lighting system and the conduit return system used in Southern California.

At the Midwinter convention in New York in February 1920, a paper on "Daylight Saving" was presented by Preston S. Millar under the auspices of the Lighting and Illumination Committee. This paper contained a comprehensive analysis of the subject and the general purpose kept in view by the author in the preparation of the paper is indicated by the following quotation from the opening paragraph of his remarks:

In accepting the invitation of the Lighting and Illumination Committee to present a paper on "Daylight Saving," the author stipulated that in order to consider the subject comprehensively, a considerable part of the paper would have to be devoted to matters remote from electrical engineering. The economic and sociological aspects of daylight saving surpass in importance the effect upon use of artificial light. Any treatment which should ignore these important features would lack perspective and would be likely still further to increase confusion on a subject which is greatly in need of clarification. Accordingly this paper includes a brief survey of daylight saving in its several aspects.

Your Lighting and Illumination Committee decided this year, as last year, to send a circular letter to the Chairmen of all of the Institute Sections, suggesting that one meeting of the year in each Section might profitably be devoted to an illumination topic. The following quotations from this year's letter will indicate the point of view taken by the Committee:

At the last meeting of the Lighting and Illumination Committee of the American Institute of Electrical Engineers held on October 10, 1919, in Philadelphia, it was decided to suggest to the Chairmen of the various Institute Sections that it might be desirable to include on the program for the current year one meeting devoted to some illumination topic.

Where the Local Section of the Institute is in a territory having a Local Section of the Illuminating Engineering Society it would be desirable in connection with the meeting devoted to illumination to have said meeting as a joint session between the two organizations.

The responses to this letter were widespread and a number of excellent papers dealing with various aspects of lighting and illumination were presented before some of the Local Sections during the course of the year.

Developments in the Lighting Field

Under date of January 16, 1920, the Chairman of the Board's Committee on Technical Activities sent a letter to the Chairmen of the Technical Committees, which contained, among other items, the following:

It was brought out very strongly at the last annual convention in the discussion of the Development Committee's report that the reports of Technical Committees should cover the activity in the particular line covered, so that anyone reading these reports from year to year would obtain a review of the progress of the art.

These reports should cover notable installations or developments during the year and it is suggested in view of the fact that in the past little has been done in this respect, that the reports might be a review of the state of the art up to date. One plan that was suggested which seemed to have considerable merit, was that the Chairman of the Committee might apportion to different members of the Committee certain parts of the field covered by the Committee's activities, and these should be edited and combined to be the report of the Committee.

Acting on this suggestion, the Chairman of your Lighting and Illumination Committee has addressed the members of the Committee in an effort to gather the important developments in the lighting field. These have been edited and combined so as to be the main portion of this report. It should be stated in advance, however, that the developments in the field of street lighting distribution, which were covered in the papers read before the Chicago meeting in January, will not be discussed in this report, since they will be found completely treated in the TRANSACTIONS of the Institute. The same statement applies to the important question of "Daylight Saving" which was covered in the paper before the Midwinter convention, and which will therefore be found in due time in the Institute TRANSACTIONS.

General Notes

As one of the results of the war, in its effects on the lighting field, a number of interesting papers have been presented during the past year. The titles of several of these papers will indicate the rather unusual character of the material which has been gathered under war conditions. Among these may be mentioned the following: "The Science of Marine Camouflage Design," "Painting Battleships for Low Visibility," "Camouflage," "The Principles of Camouflage" and "Industrial Lighting and its Relation to the War."

Following the war, the past year has witnessed an unusual increase in the interest taken in lighting in general. It has been felt that the past twelve months have, in fact, marked an awakening among the users of artificial light to its possibilities. This has been evidenced by the efforts made by various societies, organizations and associations, to have placed before them the facts as to what light can do in the way of increasing production, decreasing accidents and of improving the morale of employees in industrial plants. It would appear that a transition period is in progress in the lighting field, if one can judge by the trend of the developments during the year. Among these developments the following may be mentioned:

1. A widespread recognition of good lighting as an important aid to manufacturing.
2. The increasing use of the foot-candle meter as a means of checking illumination intensity in various parts of a lighted room.
3. Progress of industrial lighting codes.
4. Progress in automobile lighting regulations in several states.
5. Development of the bowl enameled Mazda C lamp to give better diffusion. The latest lamps of

this type have a feathered edge of the enameling to prevent a sharp "cut off" line.

6. The proposal of a plug outlet for permitting the convenient change of ceiling and wall fixtures.

7. The increasing tendency on the part of fixture manufacturers to make and advertise ready-to-hang types of fixtures. These fixtures are principally for commercial and industrial lighting but there is also some tendency to invade the residence lighting field, which seems to be an improvement both from the scientific and the commercial standpoints.

8. The formation of the fixture manufacturers association, with an attempt (as mentioned in item 6 above) to perfect a method of fixture hanging which will permit electric light fixtures to be hung as easily as a picture and moved, by the renter, as easily as a portable lamp can be moved, thus encouraging the renter to install improved fixtures as a substitute for bad designs often found to be in use when a house or an apartment is rented.

9. Progress in the enforcement of the industrial and automobile headlight codes. New York, Connecticut, California, Wisconsin and Pennsylvania have adopted the I. E. S. S. A. E. automobile headlight specifications, and it is reported that in all of these states, except New York, there are practical attempts at enforcement, which are gradually producing results that are favorable.

10. An important development in street lighting units is the "Duoflux" standard. This unit contains two lamps (in one type, one 1000 candle-power and one 250 candle-power) and by means of a relay located in the casing of the fixture, the 1000 candle-power lamp will be extinguished at midnight, and the 250 candle-power lamp lighted.

Developments in Lighting Units

The RLM standard dome reflectors have during the year become more widely adopted and nearly all the leading steel reflector manufacturers recommend these standards for industrial lighting.

Among the new fixtures and auxiliaries developed during the year, there may be mentioned the enclosing type of interior units which consist of a combination reflector, a diffuser and an enclosing globe in one piece. Another interesting development has been that of simplified units of the semi-indirect type, and the increased application of the incandescent lamp for moving picture projection. In street lighting, the single unit of high candle-power has quite largely replaced the cluster form of post, the former being considered superior both from the standpoint of efficiency as well as of appearance.

Luminous arc lamp efficiencies have been increased by the compounding under high pressure of the ingredients of the electrodes. It is reported that by this means, 30 to 40 per cent more light is produced than with the previous standard electrodes, with at least equal life. For the same light as formerly, increased life of the electrodes is expected.

Important Lighting Installations

The unusual lighting effects secured at the Chicago and the Buffalo electrical shows in 1919 may be mentioned. At Chicago, the so called "Palace of Aladdin" was housed in a structure 50 feet high, and interesting lighting effects secured with glass jewels, painted mirrored glass and flood lights. At Buffalo, 5000 *white* Mazda lamps were employed along with nearly 5000 illuminated disks distributed among the roof girders. The application of spectacular lighting of this general nature, was seen at its best, perhaps, in the "Jewel Portal for the Victorious Army" in New York and the "Altar of Victory" in Chicago. The use of 30,000 so called jewels in each of these remarkable lighting displays, contributed largely to the spectacular effects secured.

The effect of the war on industrial lighting has been to stimulate the interest taken in better factory lighting the past year. The tendency to employ illuminating engineers for the handling of industrial lighting schemes, rather than to entrust this work to the electrical department as heretofore, has been noticed. In one large industry a research is being conducted to ascertain the effects of lighting on production. The large increase in wages in the industries, with very little increase in the cost of factory lighting, has reduced the cost of good lighting in term of wage equivalents. This same fact has also made lighting the more important in terms of its effects on increased production and reduced spoilage.

A notable example of modern factory lighting installations is contained in a booklet recently issued by one of the lamp manufacturers. It would have been very difficult a short time ago to have published a book of this kind without relying upon the artist to touch out undesirable features and to paint in desirable ones. This entire booklet contains unretouched photographs of industrial lighting installations and is a commentary upon the improvements which have been made in this part of the illumination field.

In street lighting a number of important installations have been made. Among these may be mentioned the main street lighting in Salt Lake City consisting of 70 standards, each equipped with three 6.6-ampere ornamental luminous arc lamps. These units are spaced about 100 feet and the overall height is 29 feet. Although this particular system was put into operation prior to the current year, it represents an example of intensive street lighting which is coming more and more into prominence. More recent systems of intensive street lighting are the Triangle Lighting in San Francisco, first put into operation in January 1919, and the Broadway system in Los Angeles, put into operation in January 1920. The latter installation consists of 134 two-light ornamental

luminous arc standards 106 feet apart and 27 feet high. The installation cost was about $6.50 per front foot of property, and the annual operating cost is about $1.00 per front foot.

The Broadway system at Saratoga Springs is of interest in that about a mile of street is to be lighted by 69 of the new "Duoflux" units mentioned above. Each of these units contains two lamps, one of 1000 candle-power and one of 250 candle-power. This installation, which is to be put into operation about June 1920, will cost about $32,000 for its installation and for operation, about $10,350 per annum.

Contributions to the Art

Important papers contributed during the year include a discussion entitled "Coefficients of Utilization" by Ward Harrison and Earl A. Anderson, published in the March 20, 1920 issue of the *Transactions* of the Illuminating Engineering Society. This paper presents a method for the direct determination of coefficients of utilization applying to installations of all ordinary types of lighting units in rooms of varied proportions and different ceiling and wall colors. Actual colors for ceiling and wall surfaces covering 32 different shades with the corresponding reflection factors are included in the printed paper.

A paper on "Opportunities of Extending Lighting through New Applications" was read by R. M. Searle before the annual convention of the Illuminating Engineering Society in October 1919, which contains references to the following divisions of the lighting field: Street Lighting, Display Lighting, Flood Lighting, Lighting of Freight Terminals, Industrial Lighting, Stairway Lighting and Lighting for Community Affairs, this list giving an idea of some of the fields in which developments may be expected.

The following quotation from an address of President S. E. Doane before the Thirteenth annual convention of the Illuminating Engineering Society is of interest:

> The war has taught us that we have been regarding electric lighting, to use a phrase that one of my associates has given me, as a janitor service, whereas we should have looked at lighting as an item in the cost of production or in the cost of sales, and regarded it as any other factor in the cost. Then we would have examined, as have men within the last year or two, under what light we could get the maximum of visual acuity or speed of visual reaction. During the war time we have had some demonstrations. Mr. Durgin has given the most and the best of the practical demonstrations of how to apply this knowledge that visual acuity increases with the intensity of light and the speed of reaction increases production.
>
> Its application to production has been spectacular, and the results have been remarkable. As a matter of interest and as a measure of our opportunities I would like to use some figures from the lamp industry. Sixty-five per cent of the output of the lamp manufacturers, according to our estimates, is used in that portion of our business which would be affected by this knowledge. In other words, more than half of the electric lighting of this country can be affected and will be affected by the better knowledge we have of the production or increase in visual acuity and speed of visual reaction under intensive lighting.

For those who may be especially interested in the progress of the lighting and illumination art, attention is directed to the annual report of the Committee on Progress published each year by the Illuminating Engineering Society. The last report of this kind, covering 80 pages, will be found in the *Transactions* of the Illuminating Engineering Society for November 20, 1919.

C. E. Clewell, *Chairman.*

ANNUAL REPORT OF THE POWER STATION COMMITTEE

To the Board of Directors,

During the year 1919-1920 the Committee held two meetings, mainly devoted to discussion of papers presented, in person by the writers for comments and suggestions. The contributions to the activities of the Institute under the auspices of this Committee were as follows:

A symposium on steam turbine design, with the following papers:

- *Present Limits of Speed and Power of Single-Shaft Curtis Steam Turbines*, by Eskil Berg.
- *Present Limits of Speed and Power of Single-Shaft Steam Turbines*, by J. F. Johnson.
- *Present Limits of Speed and Output of Single-Shaft Turbo Generators*, by F. D. Newbury.

A plea for standardization in statistical records of state and governmental bodies reporting efficiencies of power plants, with the presentation of the following paper:

- *Essential Statistics for General Comparison of Steam Power Plant Performance*, by W. S. Gorsuch.

A symposium on excitation, with the papers to be presented at the Annual Convention as follows:

- *Considerations which Determine the Selection and General Design of an Exciter System*, by J. T. Barron and A. E. Bauhan.
- *Factors in Excitation Systems of Large Central Station Steam Plants*, by A. A. Meyer and J. W. Parker.
- *Exciters and Systems of Excitation*, by H. R. Summerhayes.
- *Application of D. C. Generators to Exciter Service*, by C. A. Boddie and F. L. Moon.
- *Exciter Practise in the Northwest*, by J. D. Ross.
- *Generator Excitation Practise in the Hydro-Electric Plants of the Southern California Edison Company*, by H. H. Cox and H. Michener.

The committee also considered the question of making suggestions for the activities of the incoming committee for the ensuing year, and recommended for consideration the following:

Safe Maximum Limit of Operating Capacity for Each Section of Bus.

Reactive Component Dispatching.

Auxiliaries in Steam and Hydro-Electric Plants.

Fighting Generator Fires.

Trend of Modern Power Station Design.

PHILIP TORCHIO, *Chairman.*

ANNUAL REPORT OF THE ELECTROPHYSICS COMMITTEE

To the Board of Directors,

THE Electrophysics Committee desires to receive suggestions for future work. It seems well, therefore, for this purpose to re-state from the report of last year the policy that this Committee has endeavored to carry out. It is as follows:

1. To encourage original papers of high technical standard, marking advances in electrophysics.
2. To have each year a broad, interesting, general lecture, free from mathematics, dealing with modern physics.
3. To promote a more complete cooperation and mutual understanding between the engineer and the physicist.

It is our object to keep open the "line of communication" between the pure physicist and the strictly applied physicist or engineer.

A joint meeting was held with the American Physical Society in Philadelphia, October 10-11th. The Physical Society session gave a notable discussion on the present status of theories of atomic structure. A review of this subject designed for engineers has been printed in the JOURNAL. The A. I. E. E. papers showed how these theories had been practically applied in the study of crystal structure and in the solution of vacuum tube problems. Other papers covered a variety of subjects marking advances in electrophysics.

Talks were given in an evening session by past presidents of the two Societies. It was the object of these talks to promote cooperation. The titles are significant—"The Indispensability to Each Other of Pure and Applied Science" by H. A. Bumstead; "Pure Science and Industrial Research" by J. J. Carty.

Additional technical papers have been given at other sessions.

F. W. PEEK, JR., *Chairman.*

ANNUAL REPORT OF THE TRACTION AND TRANSPORTATION COMMITTEE

To the Board of Directors,

TWO meetings were held under the auspices of the Traction and Transportation Committee; one at the mid-winter convention in New York in February, and the other at a regular meeting of the Institute in Pittsburg, March, 1920.

At the New York meeting there was presented and discussed a symposium paper entitled: "The Economic Supply of Power for the North East Atlantic Seaboard." This paper made reference to an item before Congress calling for a survey of the situation between Boston and Washington looking toward the establishment of a national policy in the matter of the generation and distribution of power through the means of which large economies could be effected as applying to labor, fuel and other materials.

The meeting passed a unanimous vote recommending that the Board of Directors of the Institute appoint a special committee to be known as the "Committee on Super Power System." This committee has since been appointed.

Since the above meeting, Congress has approved the proposed survey and appropriated $125,000 for the purpose.

The Pittsburg meeting included the presentation and discussion of papers relating to the design of the Minneapolis and St. Paul Electric locomotives by the General Electric Co. and by the Westinghouse Electric and Mfg. Co.; also papers concerning automatic substations and protection to substations.

Both of these meetings were largely attended and much valuable information and data were presented, all of which has appeared or will appear in the TRANSACTIONS.

There seems to be no disagreement on the part of any members of the committee in the Conclusion (1) that Super Power Systems stand as future guarantors for economical generation and distribution of power and (2) that the electric locomotive has demonstrated its ability as applying to passenger, freight or switching movement, to outclass the steam locomotive in capacity and control.

WM. S. MURRAY, *Chairman.*

DRYING FLOODED ELECTRICAL EQUIPMENT

A description is given of the methods employed to dry out an electric generator, switchboard and motors which had been under water for more than a week in a flooded basement, the water being contaminated with sewage and sludge.

A corrugated sheet iron house was built round the generator and engine, and two wood-burning stoves were placed inside this housing. A temperature of about 90 deg. cent. was maintained for five days and nights, by which time the generator was fairly dry except for moisture inside the V-rings of the commutator. This moisture was removed by heating the commutator itself, the generator being run with the shunt field disconnected and the armature short-circuited through the series winding. This stage in the process occupied a day and a half. The switchboard instruments were returned to the maker. (K. A. Reed, *Power*, Feb. 17, 1920. 3½ cols., 2 figs.)—*The Technical Review.*

Discussion on the Super Power System for the Northeast Atlantic Seaboard

Presented at the Midwinter Convention of the A. I. E. E., February, 1920

W. S. Murray: It is certainly a great pleasure and honor to stand up before such an excellent gathering of my brother engineers. I do not think that we are here today to discuss the technical features of power generation, transmission, traction, and all such problems of electrical engineering with which we are so familiar. If I could accomplish the real objective of my standing before you today, it would be to infuse in you something which I believe to be right and something that we should do.

Power, to my mind, is the father of accomplishments, moral, intellectual and physical. That statement can be qualified in a great many ways, but I think you know what I mean. Electricity is power's greatest agent. Good business succeeds if it has good agents; poor business fails when it has poor agents. Electricity is the greatest agent of power, it is power's greatest sales agent.

Did you ever realize what would happen if, overnight, for instance, iron lost its magnetic properties? It would mean that practically every steam turbine and electric generator, of over two thousand or three thousand kw. in capacity would be scrapped. Ninety five per cent of the power apparatus of this country would go out of business. Now, what does that mean? That means simply that electricity is power's greatest agent. In other words, electricity is the greatest agent in the world as a power distributor. When electricity appeared, it went in front of and behind the prime mover—it went behind the prime mover, because it increased tremendously the economy of power production, and it went ahead of the prime mover, because it eliminated the wasteful jack-shafts, belts, etc.

Now, where is its field? Its field can be divided up into five distinct parts: Industrial establishments; street railways; heavy transportation, including passenger, freight and switching service; light, and miscellaneous applications—those five. With these in mind, it should be our endeavor in every possible way to erect the channels through which electricity may flow into its rightful field, and, per contra, to erect barriers to prevent any other form of power getting into that field.

I believe if we constantly keep this in mind that we will secure a proper application of power, with electricity as its agent.

I have thought and talked a great deal about the super-power system. It has been presented on the pages of the technical and public press. I do not think that with as many splendid men as we have here who will contribute to this discussion, that a great deal of time should be taken in the description of the super-power system. I believe you all pretty well know what it is. To brief it, the idea is that in a zone between Boston and Washington, and about 100 to 150 miles in from the coast, there exists today a machine capacity, railroad and industrial, of about 17,000,000 h. p.—of which 10,000,000 is industrial and 7,000,000 railroad. The load factor in that zone is certainly not more than 15 per cent. By the installation of a system of transmission lines and radials, these users of power will be connected to power stations of high economy, constructed at tidewater at proper coaling points—to steam generating stations erected where economy predicts, at the mouths of mines, and to river stations where hydro-electric plants offer opportunity of economic development, all of these stations to be interconnected with a high voltage transmission system as previously mentioned.

It is my conclusion, as judged from general investigation, that the number of pounds of steam per kw-hr. used today throughout that zone which I have described is about 40 on the average. Prof. Breckenridge of Yale University thinks that I am too conservative on these figures. However, let us take it at 40 pounds of steam. With steam generating units of from 35,000 to 50,000 kw., this average rate will sink to 15 pounds of steam per kw-hr.

The load factor of the zone will be lifted from 15 per cent to 50 per cent,—I have seen opportunities in connection with my work on the New Haven of securing a 75 per cent load factor—and this means that we will conserve capacity to extent of three-fold, and our natural resources in the form of coal, and fuel oil, two-fold. There will be a large amount of money required for investment to accomplish this but as far as I am able to determine it, based on even the high prices we are living under today, the return will be $300,000,000 a year and this represents something like 24 per cent on the investment.

I think that that may give you a brief sketch of the super-power plan. I might say that prior to the war, the idea of a consolidation of the roads on the west side of the Hudson River seemed a very attractive field for economic returns; their operation being planned under what might be called a General Power and Equipment Company—the occurrence, however, of the war, made it impossible to carry this thought further. An idea began, however, to rise in my mind as to the possibility of an extension of these principles to a larger zone. Indeed, gentlemen, first to the house, the city, then to the district, and as certainly as I am standing up here before you, you are going to see just this thing happen that I am describing to you. It has got to be. You cannot stop it. Not to stop it means that we engineers who stand for conservation, must say "We know it, we know that there are $300,000,000 a year going to waste and assimilate the slur too often cast upon this country that our waste is enough to keep three of the biggest European powers going, and I believe that is a fact."

What is the plan? It is an investigation or survey on the part of Department of the Interior to allocate,

these wastes with recommendations for a regional plant by which they can be eliminated. There is an appropriation in the amount of $250,000 forming a part of the Sundry Civil Bill to be presented to the Committee on Appropriations between now and the 30th of June, with which to make this investigation; in other words, we want to spend $250,000, with which to point out the way an annual saving of $300,000,000 can be made.

Now, I have taken more time than I intended in presenting this matter to you. The men who have designed our turbines, and our generators and who know what transmission requirements are that large bulks of power at high efficiency may be transmitted, are here today and I have talked to them, as I have tried to develop the subject and they have encouraged me to believe that I am on the right path. They have created these engines and apparatus of economy and so made the super-power system possible.

It seemed advisable therefor to have the authors on the subject of the parts of this regional zone give us the benefit of their opinions. To that end a circular letter was written to Mr. W. LeR. Emmet, Mr. J. F. Johnson, Mr. H. G. Reist, Mr F. D. Newbury, Mr. W. B. Potter, Mr. Philip Torchio, Mr. Percy H. Thomas, Mr. W. D. A. Peaslee and Mr. A. O. Austin—these men representing, as I have explained to you, large turbines, large generators, heavy traction machines, transmissions, and insulation, all of these being parts of this great system which will be necessary to its successful operation.

Now, I shall not discuss my symposium nor the papers by the several authors, because I want to see most of these men on their feet here, so that you may listen to *them* and hear what they have got to say, and then I would like to hear from others who may have some contributions to make, and the only thought I want to leave with you is this—Prof. Scott has pointed out in an address before the National Electric Light Association that if the rate of increase of power in New England is sustained, as it is going on today, that in ten years' time the amount of power required there which is now 1,500,000 kw. will be 5,500,000 kw. That is merely in New England. All of the dense districts along the Northeastern Atlantic Seaboard are now or will be like that, and so it is not a question of how are we going to take care of this immediate future—why—the immediate future is right here—the foundations for this tremendously increasing density must be laid now for we cannot perpetuate these old methods of the past, which will only mean that as density increases the losses of today are to be increased; and so I want to leave with you this thought—that this is something that we must do and do *now!* Every *part* of it has been done. It has not been put together. That is all. We have got to start right now, and put this great regional plant together, and be ready for this expansion which is now upon us.

One other thought—one of the things that has militated terrifically against our industrial expansion is that we cannot get our materials over the railroads. Now, the installation of this proposed system will be a relief to the railroads. It means the creation of an overhead common carrier system of power, and that means that the coal that is now clogging our main lines, sidings and yards, can, in a large measure, be lifted off the rails of the steam railroads, and that will automatically create cargo space for other and higher priced commodities, thus yielding an increased return, and it also means, as any man knows who has been connected with the electrification of railroads, that the capacity of the railroads will be tremendously increased. Take the switch engine, for example. We put seven switch engines in the Oak Park yard, and they did the work of ten steam engines and speeded up the work fully 50 per cent. One of these switch engines went 40,000 miles before it had a commutator turned,—before it had anything done to it other than its routine inspection.

We have arrived at the time when we know what electricity can do for the railroads and industries in the way of cutting down this frightful coal bill, and conserving our natural resources, and opening up traffic for other and higher priced commodities, and saving enormously the maintenance cost of power machinery, both on the railroads and in the factory; but the people do not know it, and we have to educate these people so that they do know it.

Now, gentlemen, I will call on Prof. Malcolm Maclaren, of Princeton University, who has made a study of the Southern District through the War Industries Board of this proposition, and he can bring you very closely in touch with the very excellent contributions that that board made to the government during our strenuous times. We would be glad to hear from Prof. Maclaren.

Malcolm MacLaren: By way of introduction, I would like to testify to the splendid work our Chairman is doing in the cause of conservation, which is of such vital importance to us nationally in the industrial expansion which we are hoping will take place following the war. It seems to me, as we have one of our own representatives engaged in this work with such tremendous enthusiasm and with such wide vision, that it behooves every member of the Institute to co-operate with him to the full extent of his power.

During the late war I had occasion to devote most of my time to a study of the power conditions along the Atlantic Seaboard and I became very much impressed with the opportunities for procuring great economies through more extensive interconnections between systems and more effective utilization of the natural resources of the district. If the war had continued, the Government would have assisted in carrying out improvements along these lines and important developments were maturing when the armistice put a stop to the work. This need, however, is still present and is possibly even more pressing than before as a purely economic measure. With the inceasing shortage of fuel and labor, the wasteful isolated industrial steam plants should be abandoned in favor of central station power, the electrification of the steam railroads should be extended both as a conservation measure and in order to obtain increased capacity with the minimum expenditure of capital, and the power companies in their expansion to meet their increasing demands for power should seek to utilize to the maximum the natural resources available in order to maintain a cheap and reliable power supply.

On account of the magnitude of the problem and the number of varied interests involved, it is essential, in order to obtain the best results, that some independent body make a careful study of this situation, and I believe the Institute could render no greater service to this community at the present time, than by urging the creation of a commission which should direct the course that these developments should take.

In a few minutes which are allotted to me I will not attempt even to outline the scope that this in-

vestigation might take, but will confine my remarks to the consideration of the needs of only one portion of the territory under consideration; namely of Eastern Pennsylvania, New Jersey and New York City. There are four more or less distinct industrial districts within this area; one includes Philadelphia and extends along both banks of the Delaware River from Chester to Trenton; another centers about Newark reaching from Paterson in the north to Perth Amboy in the south; the third is comprised within the limits of Greater New York, and the fourth includes the anthracite coal fields extending south to Allentown, Bethlehem and Easton, which may be designated as the Lehigh District.

In order to form some sort of a picture of the possible future power requirements for this territory, I recently made a rather careful analysis of the demand which would occur at present if all of the industrial load of each district were carried from a single power system and if all the steam railroads within same areas were electrified and served from the same system. From the nature of the case the figures must be considered as approximate but I believe that they are based upon sound premises and are reasonably correct. The results show that for the Philadelphia District the maximum demand would be approximately 700,000 kw. For the Newark District 550,000 kw. For the Lehigh District 650,000 kw. No estimate was made for New York, but its demand would be probably not far from 700,000 kw., making a total of 2,600,000 kw.

The public utility companies within this territory are now carrying a little less than 1,000,000 kw. of this total. Without attempting to study the rate at which the power companies are taking over this load and providing for new industries, does it not seem reasonable to expect in the light of the above figures that the demand upon these electrical systems within the next ten years should reach 2,500,000 kw., provided a unified system is developed which takes full advantage of the natural resources of the district? The generating facilities of the power companies already developed or contemplated by present construction programs will provide for carrying about one-half of this load, leaving over 1,000,000 kw. additional to be furnished. The most promising methods for obtaining this additional capacity are:

By hydroelectric developments on the Susquehanna River.

By hydroelectric developments on the Delaware River.

By construction of steam plants at the anthracite mines.

The largest single development projected for the Susquehanna River covers the construction of an hydroelectric installation at Conowingo near the mouth of the river which will have an initial capacity of 125,000 kw., and will be capable of producing approximately 700,000,000 kw-hr. in a dry year. This is somewhat less than the present annual production of the electrical systems of the Philadelphia District, where it could be most readily used, but as it is river flow power varying in amount with the seasons and river stages, it could not all be absorbed by these systems until their loads have increased or more extended interconnections permit of a wider distribution of power. This 700,000,000 kw-hr. represents only about one-third of the energy of the river at Conowingo, and with a relatively small amount of river control it should be possible to increase the output at this point and develop other sites which should yield between 200,000 and 300,000 kw. and 1,500,000,000 kw-hr. annually.

Plans are well advanced for the development of a series of hydroelectric plants on the Delaware River which indicate that it would be feasible to utilize a very large percentage of the total energy of this river and that complete river control might be obtained without excessive cost for reservoirs. Such a system would be capable of producing 250,000 kw., of primary power and 1,000,000,000 kw-hr. annually.

Considering next the construction of the steam plants in the mines, it should be noted that it may not prove feasible in the present state of the art to install in the anthracite region super-power plants of 300,000 kw. or more such as have been proposed for other districts, as there are few if any sites in this district where there is combined an adequate supply of the smaller sizes of coal with water conditions suitable for operating a plant of such magnitude. It is probable therefore that steam plants which may be constructed in this region within the next few years will be of less individual capacity, but of sufficient number to meet local needs and furnish considerable surplus for transmitting into adjoining territory.

Purely as a conservation measure it is important that such plants be constructed at an early date for by thus increasing the demand for the smaller sizes of anthracite the conversion of these mines to electric operation should be greatly stimulated. It would be difficult to find a better illustration of the economies to be derived from the use of central station power than can be shown in this case, where heretofore there has been a most extravagant use of fuel because the smaller sizes of coal have been utilized for which there has not been a ready market. The Report of the Bureau of Mines for Pennsylvania shows that for a total annual production of 80,000,000 tons of anthracite for this district over 8,000,000 tons were used in the mine operations. Data obtained from the electrified mines of the district indicate that if all the mines were electrically operated from a central supply system this 8,000,000 tons now being used for mining coal, would be capable of supplying all the needs of the coal companies and have a balance sufficient to operate a generating system of over 600,000 kw. capacity at 50 per cent load factor, or approximately the entire power load of Greater New York including the railways.

The picture, which might be formed of a general scheme to be followed during the next ten years to meet the growing need for power within this territory, is that the power companies in the large cities should in general complete their present construction programs but should not greatly increase their generating facilities beyond this point, additional capacity being obtained by the construction of steam plants at the mines, reenforced on the east by hydroelectric plants on the Delaware River and on the west by hydroelectric plants on the Susquehanna, the whole territory being interconnected with transmission circuits. Such a system should produce a cheap and reliable source of power under normal conditions and would have the greatest flexibility for meeting emergencies, for the generating facilities would be divided in approximately equal amounts among steam plants at the large cities burning bituminous coal, steam plants at the mines burning anthracite and hydroelectric plants on the Delaware and Susquehanna Rivers; the unified system of transmission circuits making it possible to

transfer larger blocks of power to any point in distress without the use of rail transportation.

W. S. Murray: I am going to take the opportunity, unless the meeting should object, to intersperse one or two remarks between the authors' statements. I have found it difficult to describe so large a thing quickly, and you appreciate that it is quite possible in such a presentation to miss a great many things. At least keep in thought, however, that in the development of this zone, the available water power in the district looks as if it would not supply more than 10 per cent of the total amount of power required, and that later as the power requirement increases that percentage may be even less.

I do not know how near my figures may be correct but I question today, with the present labor and coal rates in New York City, whether a kw-hr. is produced for less than ten mills, may be eleven mills.

The Delaware River, fifty five miles from here, supplying a billion kw., which I understand can be placed in New York for somewhere around five mills, would show upon that basis a saving of $6,000,000 a year, thus it is important to keep in mind, though the hydroelectric power is small, that it be included in this great system, and because it is small, as I think Mr. Torchio will bring out later, its application is the easier and more efficiently made.

We have with us Mr. Riest, of the General Electric Company, who has made a contribution to this symposium in connection with large generators. I would like to say, as there is a very large number of men whom I would like to call upon, that if the speakers can condense their remarks better than I have done, I will appreciate it.

H. C. Reist: I think perhaps I will save time if I read the paper as it is printed.

(Mr. Reist read the paper).

W. S. Murray: It is, indeed, reassuring to have a man like Mr. Reist on his feet, telling us that the generator part of this system is ready. I do not think I need to introduce Prof. Scott to this audience.

C. F. Scott: Mr. Murray has a way of taking a super view of things; he is constituted that way and he cannot help it. On the New Haven Road a few years ago he had vexing problems with control wires and circuit breakers and details of daily operation, but he kept thinking of something else, of transportation in its largest sense. Later he operated a power plant and built a hydroelectric station and he had problems, of operating accounts and of foot-seconds and dams and transmission lines. But he began to think of combining power plants into a great power system to serve electrified railroads and industry; he has visualized into a super-power system all the things he has ever had anything to do with.

In our Institute records there are papers describing what we have accomplished and what we are doing and how we may do things. Here is a paper that looks forward in electrical engineering, not in theoretical research but in the service side of engineering. The vision is large; it involves too much to grasp. It is a difficult problem to get other people to understand what engineering has done and is doing and can do. I must take exception to Mr. Murray's statement that nobody understands these engineering matters except ourselves; I question whether even engineers really realize what is going on and what our accelerating rate implies.

What have we been doing in the past? What is our rate of progress? It is not quite fifteen years since we came into this building. What has been going on since then? We thought that engineering was pretty large then, but in the short interval some startling advances have been made. The annual output of the industries of the country have doubled. Our railway freight transportation since Mr. Murray began to run electric locomotives on the New Haven (which was three months after we dedicated this building) has doubled, *i. e.*, the ton miles of freight haul is twice as great; railway trackage has increased a little, but trains are longer and cars are larger and even then the augmented service scarcely meets the requirements. Industry and transportation have increased as much in a dozen years as they did in the previous century.

The use of electricity by the rule of the past doubles in about five years. Since the date of the electrification of subways and railway terminals in New York, since this building was completed, the use of electricity has increased fivefold; five times the kilowatt-hours are produced now that were produced a dozen years ago.

Consideration of this remarkable rate of increase takes the things which Mr. Murray plans out of the indefinite future and puts them only a little way ahead on the projection into the future of the curves of past performance.

As we look into the power problems in a new way surprising things appear. Professor Maclaren mentioned one a few minutes ago when he said that the first thing that is done with coal is to burn it at the mine's mouth for operating the mines. Prevalent methods involve such a waste of coal that the same coal which is now used could be burned in efficient power plants and would furnish enough electric power for operating the mines with a surplus sufficient to replace all the power plants which are now supplying New York City.

In transportation we ordinarily think of the railroad as the only important factor. But the cost of local transportation of freight for a few miles or even a few blocks in a city is often equal to the cost of transporting it 500 or a 1000 miles by rail. The present problems in transportation are at the terminals. A prominent terminal engineer predicts that the amount of electric appliances which will in future be used in the handling of freight at terminals will exceed in cost the electric locomotives which will haul it across country.

The super-power system is the goal toward which we have been tending. Engineers used to deal with the problems of making motors, generators and turbines that would run; then came problems of transmitting power. Small isolated stations gave place to larger power houses and extended systems. Then came problems of application and the use of power. A difficulty in the past has been to get the public convinced that it was worth while to use electric power. The public has learned to use power and now the great problem is the universal supply of power for all purposes.

W. S. Murray: Prof. Scott's reference to Prof. Maclaren's thought of using electric power in the mines leads me to tell you that in Logan County, West Virginia, some years ago, the amount of power in boilers scattered around the mining properties, to handle the mining processes aggregated 4000 h. p. Some bright electrical man went down there and built a central station, and gathered upon its feed lines the connections to these mines to operate them

by electricity, and when he found out what the total demand was to handle them all it was 500 kw.—it was an eight to one proposition.

Now, I say this zone to which I have referred, is nothing but Logan County multiplied 5000 times.

We have between the covers of this symposium what I consider an epoch-making presentation. I cannot find quite the words, they are in my heart all right, but not in my mind, to introduce the man who will speak to you now. I know what I want to say, but cannot quite say it Maybe I better say what was said to me of him—"Thomas, yes, a brilliant but an entirely practical man." Mr. Thomas, we would like to hear from you.

Percy H. Thomas: I have considered the problems of transmission and distribution in the super-power plant from the broadest point of view, putting emphasis on the elements which may call for new methods and variations from the usual practise. In some ways transmission and distribution are the most difficult to treat of all the problems involved. The conclusions are so fundamental. The question as to whether coal should be burned at tidewater and near the consumption centers or whether it should be burned where it occurs or near there, and transmitted over transmission lines, remains yet to be settled. I have at the direction of our Chairman, practically assumed for the purposes of this discussion, that the power stations should be located near the mines and the power transmitted,—that is to say, I have presented the best case I can for the *transmission* of the power.

In assuming the mine location for the power, I have not overlooked the matter of condensing water, for the importance of cooling water for condensers for the steam units is frequently emphasized, and surely, it is of great importance. However, I feel sure that with a radius of thirty or forty miles from any coal region we could perhaps find a site or group of sites in which this fundamental problem can be solved. It is not really as fundamental as some of the other factors. Perhaps, we will have to make a large lake, and use the water over and over, use natural or artificial cooling, but I do not propose to go into that subject at the present moment.

Referring to the general scheme here proposed Fig. 1 shows a typical transmission line that might be utilized for tying together the whole district. The numerical values I have given as to cost and regulation are based on this system. It is an advantageous layout in that all the principal centers are tied by a tie which does not regularly transmit large bodies of power for a long distance in any one direction, but only interchanges power, partly primary power from the coal fields, and partly emergency power from those plants near any point in distress. It would enable, for example, the output of a couple of large units installed in Newark, to be used for a new load in Philadelphia, until after awhile perhaps Philadelphia had installed some units of its own and vice versa.

I think you will agree that the operating characteristics of a system like this shown in Fig. 1 would be relatively very favorable. This is, of course, a most important matter when we come to tying the whole super-power plant district together.

The dominating question which I think is going to determine whether it is better to burn coal at the distributing centers or near the source of supply, will be the first cost of the necessary transmission line to transmit the power if we burn at the mine mouth. This is determined by the cost of the physical structure, in the first place, and secondly, by the capacity of that structure. Therefore, I have done my best to get a favorable solution from both points of view, as will appear in the paper.

To make the case a little more concrete, I have assumed we would start perhaps two years from now, on the theory that new load hereafter connected in this whole district would be carried by the installation of new power plants at the soft coal and hard coal districts, and at a later period by some large hydro-electric supply, as from the St. Lawrence River, or possibly from Niagara Falls. This would permit the now existing systems to regulate voltage and take care of distribution and things of that sort, and would facilitate the step by step introduction of the new scheme, starting with the existing situation. To give the most favorable justification for building the high voltage lines as shown in Fig. 1, I have assumed they would be built and extended from time to time to the point that their capacity would be approximately equal to the maximum 24-hour demand of the district, so that these stations could run 24 hours a day. Then the existing plant in the present power stations would be used for the load peaks and emergencies. It is surprising how small an addition to the group of existing plants a large power plant, 300,000 or 400,000 kw. appears to be.

There does not seem to be any hope of using a higher delivered voltage than 250,000, and I have taken that value. I believe, by the time such a system could be developed that this voltage could be suitable, so my discussion assumes the delivery of 250,000 volts at the distribution points, which means 275,000 to 280,000 volts at the generators. This is one voltage step beyond the 220,000-volt group which we are now prepared to deal with in actual installations.

I calculate that a line can be built with a single circuit of three wires, that would transmit 400,000 kw. for 150 miles with an energy loss of about 5 per cent, and a regulation, that is a drop in voltage at full load, of approximately 9 per cent. That is based on the assumption that the load will be delivered at 99 per cent power factor lagging. Ninety-nine per cent is not the power factor at which the load can be most easily absorbed, but it is very helpful to the transmission line, and I am inclined to believe that the most satisfactory working out of the system as a whole will be to so modify the distributing plants, if necessary, that they can absorb power at this power factor. When you consider the inefficient steam units that can be shut down, leaving the generators as synchronous generators, and the new applications of power which perhaps can be supplied in such a way as to have a leading power factor, for example, the railroad, I am not so sure that the securing of this power factor may not be a relatively easy matter.

This line I have been describing has a rather interesting characteristic. If you short-circuit one end, and maintain voltage at the other, it will pass only four times full load current, and this without taking into account any current-limiting effects of transformers or generators. This fact was a great surprise to me at first, and I think it will be a surprise to a good many others. You can see the great operating help it will be, however, in linking together a number of these stations. It removes one great objection to carrying the idea of a super-power plant a little further, if, for example, we should ever interconnect Niagara Falls and Buffalo and Pittsburgh, and a large

number of other stations widely scattered, it would be possible to have a short circuit at any one point that would not affect other cities one or two hundred miles away, because the interconnecting transmission lines would for the time being maintain a drop equal to the full line potential and without a flow of current which would either destroy them immediately, or be beyond the power of circuit breakers to open. This is a feature of much practical importance.

The full load loss in line is at a minimum when the delivered power factor is practically in unity, and that is the reason for assuming the power factor as 99 per cent in my discussion. The line drop depends primarily on the self-induction. The effect of self-induction is electromagnetic, one-half the square of the current times the reactance of the line represents a certain amount of energy which goes into the magnetic field around the wire, and comes out again a half-cycle later, and must be supplied from the generator, but is never delivered to a load. It lags 90 degrees from the voltage. In a high-tension transmission line energy passes also into an electrostatic field supplied by charging current; that is, there is a second flow of energy from the generator which never gets to the receiving end, which is stored in the electrostatic field. This flow is exactly opposite in direction to the lagging flow with unity power factor. As a matter of fact, if the transmission line is so proportioned and the load and voltage on it so chosen that these loading and lagging quantities are equal, they disappear and the generator is not called upon to supply either one.

The net results is that the current that flows transmits energy practically the same as if it were direct current. This is exactly accomplished only with unity power factor, because only under that condition is the energy which goes to the magnetic field exactly opposed in direction of flow to the energy in the static field. When you remember that with the conductors I have chosen here the reactance is something like seven times the resistance, the effect of eliminating the influence of reactance on regulation becomes very important. It is necessary only to increase the section of the conductors to get any desired reduction of the loss of energy in the line. The transmission line circuit of Fig. 1 which carries 400,000 kw. has three conductors in each phase, 600,000 cir. mil. aluminum (with steel core) or it might have the equivalent in copper. This balancing of reactance against capacity shows why on short circuit this transmission line will not give an excessive current. On short circuit the voltage largely disappears—that means the static energy, the energy which goes into the electrostatic field and which has been relied upon to neutralize the energy stored in the magnetic field, has disappeared, and the predominant effect of the reactance factor is established; except for the line capacity, the full regulation of this line would be of the order of 20 to 30 per cent. We could not get 400,000 kw. from a circuit with this amount of conductor.

I have assumed that the line conductor in any phase which would normally be a cable about two inches in diameter, is divided into three parts, these three parts being separated by perhaps eighteen inches, making nine wires for the single three-phase circuit, three in each phase. That separating of the cable into three parts has the effect of reducing the reactance, as you can see, and this is a well-known expedient in other applications. It has also the effect of increasing capacity in approximately the same ratio. It also has the effect of raising the corona limit.

While I have not determined exactly the factor by which the capacity is raised, and the reactance lowered it can be made in the neighborhood of 0.6. In my calculations I have assumed that the reactance of the three wires separate is 0.6 of the reactance that would exist if they were in one single conductor, and similarly for the capacity.

The reactance being smaller, lowers the amount of energy stored in the magnetic field, and the capacity being larger increases the amount of energy stored in the electrostatic field, and as a result, to get a condition in which one balances the other, it is necessary to increase the load inversely as the square of 0.6, and that is, it increases about three times the load that is necessary to put on the line, to get the ideal balance conditions of reactance and capacity, so that in the case of the line which with the ordinary use of the same weight of conductor would have its limit at 125,000 to 150,000 kw., by this expedient has its limit at about 400,000 kw.

The mechanical features of the line are important. How will this division of conductors into three parts affect the behavior? These mechanical matters must be worked out in detail, and they surely can be. It is only a question of cost, which we cannot stop to consider now.

I have assumed, and here most of you perhaps will differ with me, that no spare transmission line will be provided. This would greatly reduce the costs of the original installation, and it would also greatly reduce the complication of switching. In justification of this omission of a spare line, it may be pointed out that there occur occasional disasters which deprive local districts of the use of present power house systems temporarily, or the railroad service, but the community nevertheless, succeeds in getting along one way or another. Personally, I am inclined to think so far as a breakdown on one of these transmission circuits would disturb the community it is better on the whole to makeshift than to attempt to give absolute continuity of service. The failure of a line would at the most cut off only 20 per cent of the total power of the district, and since power can be passed backward and forward anywhere in the load district, this failure must occur on the peak to cause an actual shortage.

There is one thing to which I would like to call your attention—if New York and Philadelphia are connected by a high voltage line in order that in case of breakdown in Philadelphia, New York will supply a couple of hundred thousand kilowatts, or vice versa, the flow of energy between these cities should occur without any material change of voltage, because if, when transmitting power from Philadelphia to New York, the voltage was 10 per cent higher in Philadelphia than in New York, it would follow that when transmitting the power in the reverse direction, the voltage at Philadelphia would be 20 per cent lower than normal, which could not be satisfactory. With the line here proposed, in which the reactance is high, and the resistance is low, it is possible to transmit power in either direction in large quantities without altering the voltage on either end. This is done by changing the power factor of the energy which flows—raising the generator field current at New York will tend to raise the New York voltage and make up for ohmic drop due to energy flow from Philadelphia. There is no new principle involved here, and if you will make the calculations by the well-known formula, you will find that there will be no difficulty in main-

taining a higher voltage at the receiving station than at the transmitting end.

This is a very favorable condition. It means that each center, Philadelphia, New York and Baltimore, can maintain its own voltage as may be desired, and the power can be transmitted automatically either way by a suitable combination of governors and field regulators, working on the field currents of the main generators in each center.

I have made some rough estimates as to what this system would cost, *viz*: $164.00 per kw. including generating equipment for 800,000 kw. with 12.5 per cent spare capacity transmission, and interconnecting tie lines, transformers and switches. Of that $164.00, $100.00 is for power plants.

If a power plant be located in a large city on tidewater, especially if it is a city like Philadelphia, I think the cost would be something like 25 per cent greater than for a power plant built on some favorable site away from city conditions. This is partly because on tidewater, foundations are usually very expensive, and because power must be distributed through underground cables with the high tension line, there will be a new point of contact with the distributing system.

W. S. Murray: Mr. Thomas has visualized to you what I could not so well do, because of his intimate knowledge of transmission facts. He is bringing the districts together, he is building the thing right before your eyes—the expansion from house, to the town, to the district, and now to the region. He has left with you the thought of power stations separated by hundreds of miles yet with losses between them of only five per cent, through this wonderful interrelation of capacity and inductance. It must be as clear to you, as it is to me. It puts stations widely separated next door to each other so that there develops before our eyes not so much the advantage of diversity factor, which we hear so much about—of course, diversity factor is important—but what is going to count to a still greater degree—diversity economy.

How often have any of you had the experience of having to operate low economy machines when there stood idle in the next district a machine with an efficiency equal to your most economic machine. The advantage of diversity economy is in picking the high economy machines out of any station and placing them on the zone bus. That is what we want to get. Get this great industrial district tied together. Mr. Thomas has touched on one of the most important points in the whole thing, and that is why we were all delighted to have him take so much time. I ask if Mr. Johnson is in the room? I fear he was not able to be with us. We have not had any discussion with regard to electric traction, and Mr. Storer has honored us with his presence, and I am going to ask him to make a few remarks, and as our time is passing rapidly, if he will confine himself to about ten minutes, I will appreciate it.

N. W. Storer: Mr. Murray in his symposium has referred to a paper which I presented a couple of months ago in Chicago before the Western Railway Club, on the general subject of Electrification. I touch on electrification, because that is the only point from which I can approach this paper which has been so admirably presented. Electrification means conservation of fuel and labor. At the present time we are in need of both. The United States was never so short of labor as it is right now, and I see no chance for the situation to be made any better in the near future.

Now, the railways, as I have said before, need to take a leaf from the experience of the housewives of the country. They must "do it electrically." You will find in every household in the country, the introduction of electrical appliances wherever the power supply is available. These are installed to save the labor of the housekeeper and they do it. Of the multitude of appliances which are put in now, one who is not a housekeeper can scarcely begin to think.

If the railways would electrify, they would find the same reasons for so doing, find just as great economies in labor as the housekeeper does,—they would find not only that their motive power costs less, but that at other places along the line, where power can be substituted for manual labor, it should be done, and can be done with much greater economy than they can possibly do it with manual labor.

Railways simply are not able to get labor at the present time. That means they cannot give us the transportation. It cannot be done at the present stage of the labor market, and unless they are able to go ahead and make some changes in their system, such as by electrification, they never will be able to give us what we need in transportation, and that means the greatest handicap that can be put upon the prosperity of the country. Now, the question of the conservation of fuel has been touched on very thoroughly, and I only want to refer to it briefly. In my Chicago paper I quoted from other authorities, the fact that possibly two-thirds of the fuel now used by the steam locomotives could be saved if the railways were electrified. A representative of the Fuel Administration questioned that—he wanted me to show him the figures. I had not the figures at hand at that time, but I went at it after I got home, when I had a little time, and the result was that I was more than ever convinced of the truth of that statement.

I was especially convinced of it after reading a paper by Mr. Muhlfeld, an ardent advocate of the steam locomotive, in "The Railway Age". In that article Mr. Muhlfeld, gave figures showing the coal and water consumption of steam locomotives and their auxiliaries which, to my mind, would condemn the whole system. It was no trick at all to take his figures and show how the electric locomotives would save two-thirds of the fuel. He said that the present steam-driven air compressors on the locomotives took from 70 to 85 lb. of steam at 200 lb. pressure to compress 100 cubic feet of free air.

Now, that is anywhere from seven to ten times as much power as would be taken to do that same work with an electric motor. It is an extremely wasteful proposition to do it with the ordinary single-acting compressor. He was pointing out where they could save energy by substituting a cross-compound compressor which would save probably one-half or possibly two-thirds of it, but still the power taken by these auxiliaries is enormous. Just that air compressor with 70 to 85 lb. of steam for 100 feet of air, amounts to something like 150 or 160 h. p., and maybe 200 h. p. It is not, as I repeat, a difficult matter now to show that the electric locomotive will do the work, and do it better, with one-third of the fuel that is now used by the steam locomotives.

W. S. Murray: Gentlemen, we have on our list here one who has contributed a wonderful paper to this symposium, one whom we have reason to admire

and respect for his splendid operating experience. I have always maintained the ground that after all this proposition is but an expansion of the central station business. Some have the idea that the super-power line was the major adjunct. It is not, it is simply an important and contributing adjunct, but the essential element at stake is the greater production of electric power, and its application to the railroads and industries and expansion of inter-connection will continue, until the primaries of today shall become the secondaries of tomorrow. That is the whole thought.

$300,000,000 is a large sum to waste annually. The time will come when you, as engineers, have to stand up and consider the proposition from a national point of view. It is not a question of whether we are going to hurt the private interests—I am not advocating any such thing. I want to preserve them and let them continue in the marvelous developments which they have made in producing such efficient power as they have done,—but I want that activity extended and enlarged and I do not think that the Americanism of the near future will halt this movement. The need for these things is pressing upon us most constantly.

I have talked recently with some of the most important central station men in this country and I have not met anyone as yet who does not realize, as a good American, that this proposition is coming, that it is going through, and they are going to help it.

The question of private interests handling the matter of finances is another problem. If there are $300,000,000 going to waste, and there is a return of 24 per cent by eliminating this waste, the problem will be financed. It may be financed by the private interests themselves, or it may be financed by the private interests guaranteed by the States or the Federal Government or both, but it will be financed. Away back, before we had a nation, the government guaranteed the bonds to lay the rails that were necessary for our trans-continental lines that the country might be developed, and, if it is necessary, the government will guarantee the bonds on this construction, in order that the conservation of our natural resources may be made secure. With these few remarks I would like to present to you Mr. Philip Torchio, Chief Electrical Engineer, N. Y. Edison Co.

Philip Torchio: One of the main features that every speaker has emphasized is the question of the saving of coal by railroads. In that connection I would say that our Chairman was one of the foremost leaders in calling attention to the conservation of coal by electrification, and to the proper way of electrification by supplying the railroads with power from central stations. Mr. Murray for the Railroad and I for the Powers Companies had the pleasure of negotiating one important contract and writing some contributions for the Franklin Institute about six years ago. Since then no railroad electrification has been carried out in this country that has not used central station power.

Now, I want to just briefly touch the high spots in this discussion. These papers are presented not so much from the engineering standpoint, but more from the engineer-citizen standpoint. We as engineers must review the facts from an unbiased standpoint, both for the United States as a whole and for the territory that Mr. Murray is considering. The notes in my contribution embody some views that I gathered from long experience in power matters and power plant operation. These notes are several years old and cover all the United States, but the conclusions arrived at in that case apply also to the case under discussion today.

The first question to determine is, where is the power for this nation to come from? Briefly, in the western states, water power is the logical line of development, because they have immense resources that can supply at the present time six times the requirements for "power and heat" in that territory. Therefore, water power developments in the western states must be considered as basic and pushed forward with all possible energy.

In the eastern states, east of the Rocky Mountains, if you will look at the table that I have prepared a few years ago, and which was based on the use of coal and power in the year 1915, you will see in the column "Total energy (in millions b. t. u.)" that the aggregate use for primary power, and for heating showed a total of 3,786,000,000 units. You will also find in the same column that all the water powers available in all these states amount to 300,000,000 units, or 8 per cent of the total heat units used in 1915. This shows that this country must, forever, as far as we can foresee, use coal as a source of energy.

If that is the case, we have to study to what extent we can use the water power to save coal. If all available water powers had been utilized, they would have represented something like two-thirds of the power used in 1915. I suppose that of the power used in 1919 they would represent about 45 per cent. Prof. Scott has said that we are doubling the power requirements every five years so that it will be only a few years when even with all the water power developed, we shall need to generate from coal the much greater portion of our power requirements.

If such is the case, it follows that we must develop the steam plant and the facilities in connection therewith. The previous speakers have borne testimony to the great progress made by central stations in this country in the last fifteen years; we must advance their progress still further and give them all the aid possible.

There is no doubt but the central stations today are the only coal conservators of the country. After all is said and done, the power engineer of the central station company, who goes next door and shuts down a plant that uses three times the coal the central station plant uses for the development of the same amount of energy, is a conservator of the nation; the manufacturer's motor salesman—the consulting engineer who brings about electrification in any form is a conservator of the country.

There are questions of detail as how to electrify. Should the station be at the seaboard or at the coal mine, and the power distributed over long distances. That may be a disputed question. Mr. Thomas took the view of getting nearer the coal mines. I feel a preference for having the power plant located nearer the large centers of consumption. I am perhaps a little too conservative. I feel, unless there is a very great advantage to be gained, that we should not jeopardize too much the insurance of the continuity of service.

At any rate I want to make the point that if we electrify the railroads, and bring about this interrelation of the production and distribution of power as is described in this paper presented by Mr. Murray, that we can realize the same saving, whether we place

the power plant at the water front near the large centers, or at the mouth of the coal mines, or any other place.

In fact I have demonstrated, in this Table I, assuming we could electrify all the nation, that we would save two-thirds of the coal used for producing power, so that the railroads would have to carry only one-third; the difficulties of transportation would then be very much simplified, and that one-third of the coal still to be carried, would represent perhaps only twenty-five per cent of all the coal carried, including the coal for heat which the railroads must carry in any case.

I made the point that the central stations are the logical vehicles of developing this plan. We ought to continue to do what we have done in the past, increase the interconnections, that is, tie connections between the large centers of generation and distribution.

Incidentally, if Mr. Thomas will allow me, I would rather use a little lower voltage, because if I have to go from here to Albany, and have to pick up a lot of small loads at Poughkeepsie and other places, I would rather handle a sub-station of 110,000 volts or 150,000 volts, than 275,000 volts. It would cost considerable less and be safer.

The potential savings are there. We can realize them in one way or another. The engineering problem is only a question of detail.

One prominent feature referred to in my paper is the question of utilization of water powers. We are very poor in water power, in the east except at Niagara Falls and on the St. Lawrence River, where enormous amounts of power could be utilized. I make a plea that this country should dedicate its water powers to the development of such industries as need continuous power for 365 days in the year, and continuously 24 hours a day, because we can not produce certain electro-chemical and electrometallurgical products, unless such cheap power is available. The utilization of water powers with irregular flows must be only in cooperation with large steam plants. It must be as an annex to a steam plant system.

The question of the utilization of continuous water powers, is one thought that ought to be given considerable consideration, by the national and state officials, they should visualize what are the real advantages to the nation. The relative values of water power and steam power which I have given in the paper may be of some value to anybody who desires to evaluate these conclusions in terms of dollars and cents.

W. S. Murray: W. B. Potter, just before he left last night for Schenectady, on account of an appointment he could not avoid, expressed his regrets to me for not being present today, and he advised me that Mr. Dodd would be on hand to represent him. In connection with the traction field we would like to hear from Mr. Dodd, and if he will honor us with a few remarks, we will very much appreciate it.

S. T. Dodd: In the first place, let me call your attention to an apparent discrepancy between the title of our contribution and the subject as it has actually worked itself out. Mr. Murray asked us to present a contribution on "Heavy Traction Locomotives." When we began to consider the question of type of locomotives which should be recommended and discussed for this proposition, it appeared to us that there was a great deal broader question underlying the whole thing than the question of detail of design of locomotives, and that was the question as to what was the field for these locomotives. You will find that our contribution touches slightly on the question of design of locomotives, but discusses rather fully the field which is open for heavy electric traction; but possibly our contribution fits in better with Mr. Murray's ideas than if we had confined ourselves to the actual subject given in the title.

In looking over the field to be covered, we find the majority of electrifications in the United States are included in the super-power zone. We have presented in our tables the statistics of some nine steam railroad electrifications included in this zone. We find that in the zone there are 380 miles of electrified route, some 1500 miles of track, 230 electric locomotives, and roughly, about 1000 motor cars doing heavy suburban service, so the problem presented is simply the problem of extending to a larger field the same type of traction and the same type of locomotives that have already shown such splendid results.

The first question is, what is the extent of that field. To get some data on that we have taken the official reports of the various roads which traverse the section in question, and tabulated the mileage of the several divisions, thus determining the percentage of the mileage included in the zone. We have applied that percentage to the number of locomotives in service, the ton miles moved, the amount of coal consumed, and it gives us approximately the total railroad traffic which would be included in this zone. Our Table II shows there are 12,000 miles of railroad route; 30,000 miles of single track; somewhere about 8000 locomotives working in the zone at the present time; that the locomotives run about 185,000,000 locomotive miles; they are hauling about 170,000,000,000 ton miles annually and consume about 21,000,000 tons of coal.

In getting at that question of ton miles, we have taken the gross ton miles of freight, the passenger car miles, the locomotive miles, each multiplied by proper factors, to reduce them to ton miles. We have added a certain percentage to cover the amount of switching service, and we finally come to this total of 170,000,000,000 ton miles.

The next question is, if the railroads were electrified what would be the amount of power required to move the same traffic electrically? We have checked that up in two ways. We find that something like 6,000,000,000 kw-hr. per year would be required. This is an outside figure, and will be reduced, when we cut out the amount of coal which would be saved for industrial service; but as an outside figure we can say that it is 6,000,000,000 kw-hr. per year, or an average of about 750,000 kw.

So our conclusions are, something like 750,000 kw. would be required to move the railroad traffic in this section, that there would be a saving of about 14,000,000 tons of coal per year, and there would be still further indicated a saving in maintenance which we have guessed at $15,000,000 per year. We have simply tried to give a broad general view of what the railroad problem is in the super-power zone, and to show that the problem is simply a question of the extension of the same type of railroad electrification and the same methods which are used in other electrifications throughout the country.

W. S. Murray: We have enjoyed hearing from Mr. Dodd, particularly with regard to the matter of coal consumption. I think it is interesting to note that the figures which I arrived at, showed 12,000,000 tons, Mr. Torchio arrived at 13,000,000 tons and Mr. Potter and Mr. Dodd at 14,000,000 tons. That looks like pretty close checking.

One of the things we have not touched upon and for which I blame myself a great deal is in not having a contribution upon the matter of industrial power. I would like to ask Mr. D. B. Rushmore, whom we all know for his interest in industrial power matters, to discuss the industrial power situation it this zone.

D. B. Rushmore: I would like to say that all discussion should end in action, and I would like to see some action taken on this proposition, if agreeable to Mr. Murray—I would like to see this meeting pass some kind of a resolution or suggestion, suggesting that the Board of Directors of the Institute appoint a committee, and I need not say who would naturally be the head of the committee, to take such action as behooves the Institute in following up this work, so that it can be investigated and discussed and rounded up; and I do not think any of us need to assure Mr. Murray of the cordial and hearty support he will receive from all the members of the Institute in carrying on this work, which, if he does aim at the solution he has presented today, must help to solve the problem that has got to be solved.

W. S. Murray: I cannot express to you how deeply your words of encouragment have affected me. I will relinquish the chair in favor of Mr. Rushmore, so that the meeting may take such action in regard to the matter suggested as he and you may deem expedient. I will ask Mr. Rushmore to take the chair.

(Mr. David B. Rushmore in the Chair).

D. B. Rushmore: Gentlemen, we have had a wonderfully interesting discussion, we have had a discussion on a subject looking into the future, a subject of real fundamental and practical importance, no idle dream—it is a problem that is going to be and must be solved. While we may ask the government to take a part in it, and certainly the government, representing ourselves, ought to do its part, the fundamental principles of the engineer's life is to do things for himself, and I think Mr. Murray, who has brought the subject before us, has done a really very valuable service. As many men have said, there always comes a time when the period for discussion ends, and the period for action begins. I should like very much to entertain a motion, looking to some definite action to be taken as the result of the discussion we have had.

H. W. Buck: Following out the most excellent suggestion regarding the appointment of a committee, Mr. Chairman, I would like to offer the following:

Moved: That it is the sense of this meeting to recommend to the Board of Directors of this Institute to appoint a Committee, of which Mr. Murray shall be Chairman, to carry along this most excellent movement which he has initiated today.

(The motion was duly seconded and unanimously carried).

(Mr. W. S. Murray in the Chair).

Mr. Peaslee: I will take a very few minutes of your time to give you an addition to this small contribution I was privileged to make to Mr. Murray's paper, and to say that the results of our research since the presentation of this contribution to Mr. Murray, in the case that our conclusions are not based upon optimism, but upon accomplished fact, and we are ready to undertake to do the installation of the transmission line at any voltage up to 250 kv., if you care to build such a transmission line, and we can undertake to guarantee the insulation of it with a perfectly tried unit that we are willing to go behind. We have so much confidence in it, that our directors have just authorized me to treble the capacity of our plant to take care of the manufacture of such insulators.

W. S. Murray: I want to take this opportunity of thanking you on behalf of myself and for our able contributors for the splendid and encouraging meeting which we have had. I also appreciate the importance of the action which you have just taken.

I said that after the authors had presented their contributions, we would have discussions from the floor. There is one gentleman who is with us who is entitled to our highest respect as one of the greatest central station operators in this country, Mr. Lieb. If Mr. Lieb can honor us with a few words concerning this project, we would be glad to hear from him.

John W. Lieb: I have not any prepared discussion but like all engineers, I am intensely interested in the problems that have been presented here today. The Institute and the nation owe a debt of gratitude to Mr. Murray for having organized this symposium and for having communicated his enthusiasm to the authors of the contributions which have been read, stimulating a wide national outlook on one of the most important economic problems of the day.

It is fortunate, that such a movement has been initiated just at this time, and it should have behind it the momentum and the energy that can be supplied by this body. We should not duplicate the mistake that was made when railroad electrification was first discussed, spending several years in the "battle of the systems" which alarmed the financial interests and made them hesitate to proceed with the work of electrification for fear they might make a fundamental mistake by choosing the wrong system.

Every day that the consummation of such a plan as presented in this symposium is delayed, makes its execution more and more difficult.

It is not merely a question of what the central stations might be prepared to do, and the cooperative spirit they might manifest. It is a question also of the public and the consumers. To effect this tying in of regional systems, many of them might have to change their voltage or the frequency of distribution.

I would like to refer to an experience under war time conditions which has greatly emphasized the need of a nationwide point of view in laying out a plan of this kind. During the war difficulty was experienced in meeting enormous demands for power, far exceeding the available sources of supply, in one district, while at the same time there was a large excess of power in an immediately adjoining district.

Study of the problem showed that what was needed in New Jersey for instance and needed urgently for ship-building plants and extensive war industries, was 60-cycle current. Unfortunately, the service standard obtaining in New York was 62.5 cycles. It was purely accidental that New York, in common with some other localities happened to have a frequency of 62.5 cycles.

The result was that the large surplus of energy unutilized in New York could not be made immediately available in New Jersey. A few days before the armistice was signed, a contract was ready for execution between The New York Edison Company, and The Navy Department to make available 25,000 kw. in New Jersey, but in order to do that, arrangements had to be made to generate that current independently of the general system using 62.5 cycles, so that 60-cycle current might be sent across the river into Jersey.

This matter has been taken up recently, and having

in mind possible future developments and the importance of linking-in and tying-in with adjoining regional systems on the Atlantic Seaboard the New York systems have been standardized on the 60-cycle basis. I want to emphasize the desirability of not postponing action of this kind because every day of delay enormously increases the expense of making such a change. Every day sees the installation of new apparatus on the customer's premises, and where it becomes necessary to make changes in this equipment it may be very costly and serious questions arise as to who should bear the expense of the transformation.

I would like to place proper emphasis on the necessity that arises in great communities like New York, Chicago, Boston, Philadelphia, etc., of being assured, not of relative continuity of service, but of absolute continuity of service, as far as money and human foresight intelligently applied, on a sound engineering basis, can provide. We must provide for the protection of the lighting and power service against all hazards, in view of the importance to the community of maintaining its street lighting, telephone and telegraph service, energy for the high pressure fire pumps, the lighting of firehouses, the fire alarm telegraph system, police stations and many other services absolutely essential to the life of a great center of population.

I think that the time has come, and Mr. Murray with broad vision and foresight has sensed the psychological moment, when this plan of intercommunication of regional power systems should be taken hold of as a broad national problem of supreme importance. The Institute owes a debt of gratitude to Mr. Murray and the authors of these contributions who have so admirably, so effectively, brought this matter forward. We engineers should stand behind it and emphasize its importance to our economists and to our legislators—they depend on us to present the problem and demonstrate its economic importance,—so that the public may have the advantage of the carrying out and development of this great economic policy.

W. S. Murray: The discussion is open to any who may desire to contribute. I would say to you that it is now twenty minutes after one, and I will stay here until midnight, if necessary. If anyone desires to make any remarks, the floor is open, and if anybody desires to leave, no one will feel badly about it.

There apparently being no further discussion, I declare the meeting adjourned.

F. M. Farwell (by letter): I have read with very great interest the symposium on the Super Power System conducted by Mr. W. S. Murray in the JOURNAL for March, and I should like to be permitted to make a few comments on the subject from a somewhat different angle.

Mr. Murray and the other leaders in the profession who joined with him in the symposium have left very little doubt as to the desirability or the feasibility of a super power system such as that presented in the symposium. The idea of such a system seems to have been on the mind of the engineering profession for several months. The able manner in which the matter has been presented by Mr. Murray will add to that interest and should bring about a thorough discussion of all points. The scheme does not seem to offer serious difficulties in either the generating units or the line; but the link which ties the two together seems to have received very little attention thus far.

The switching of large blocks of power, such as are at this time found in some of the larger power systems is quite a serious matter. On such systems short circuits become exceedingly destructive unless oil switches of high rupturing capacity are used. It is customary in large power stations to make all of the principal oil switches of high rupturing capacity so as to take care of a short circuit on any part of the system. In some cases, however, a selective switching scheme is used so arranged that when a short circuit occurs the smaller switches are held closed, forcing another switch of high rupturing capacity to open the short circuit. By this means the number of oil switches of high rupturing capacity may be cut to the minimum.

In the growing tendency toward interconnection, the matter of the increased synchronous generating capacity tied together and its effect on the rupturing of short circuits has sometimes been given too little consideration until the occurrence of a severe short circuit has called attention to it in a manner both forcible and disconcerting. The generating capacity tied into the proposed super power system would be enormous and all this capacity feeding into a short circuit on the system would necessitate dealing with forces of very great magnitude. In case present power stations and distribution systems were connected to the proposed super power system, it is likely that most of the switching equipment in these present systems would be utterly inadequate for the opening of a short circuit with such enormous generating capacity behind it. This would probably involve extensive changes in the switching equipment.

The problem of switching these enormous quantities of power can, I believe, be taken care of in various ways. One way would be to provide the oil switches of the local system with lockout relays so arranged that these oil switches would remain closed on a short circuit until the super power line was disconnected, then let the local switches open the short circuit. Another plan would be the use of a system of selective relays arranged to open the switches in sequence, separating various buses and lines connected in parallel in order to increase the reactance in series with the short circuit and to localize the short circuit and finally select a switch having adequate rupturing capacity to open it. A third method would be to use a system of high reactances which are normally out of circuit but which in case of short circuit would be automatically inserted into the circuit before the oil switch was finally allowed to interrupt the current flowing into the short circuit. It is quite probable that a combination of some of these would be the most satisfactory.

Just how to bring about the accomplishment of such a great project as this super power system is a matter that will bear some further discussion. Three principal elements are interwoven in the scheme, central station power and distribution systems, the railroads, and the common tie lines. As a means of saving coal the electrification of the railroads looms large but except as an additional consumer of power, the railroad part of the project is independent of the electrical system. When assured of a reliable source of supply of electric power the matter of electrification will be entirely a matter for the railroads themselves.

It seems to me that the first part of the scheme to be put through should be the tie line. It is customary for most central stations to have a certain amount of reserve generating capacity in the station to be used in case of breakdown of a generating unit or of

an abnormal load. The interconnection of several stations containing such reserve units will permit of a greater load than before on the group as the safe reserve capacity required will not be so great since it is unlikely that breakdowns would occur in more than one station in the group at a time. The diversity characteristics of the load would also improve the load factor.

The great increase in the cost of labor is going to mean the ever increasing use of machinery to do the work and this naturally means more electric power required. Many industrial establishments are now using central station power; energetic missionary work on the part of the central station companies will add much more industrial load to this. It is possible also that some of the big industrial concerns having their own power systems and utilizing the waste products of the industry such as steel works, for instance, might be induced to tie in with the super power system.

Thus, by pooling all the principal generating stations in the district and reducing to the minimum the idle reserve required for cases of breakdown and overhauling, by the use of the tie line, it is likely that a larger industrial load could be carried than now without increasing the present generating equipment. When the load reached a point such that the generating stations then connected in on the tie line could no longer handle it with safety then the big stations at the coal fields with the high capacity generating units should be built and utilized, retaining the less economical of the present stations as the reserves until such time as it became advisable to abandon them and replace with more modern stations.

It is thus seen that the building of the tie line will first enable the utilizing of the most economical units now in service or being installed in the super power zone and the holding of the least economical units for reserve use in emergency, and second, permit of the handling of considerable additional industrial load without further increase in generating capacity. It would seem to me that much of the money needed to finance the tie line could be furnished by the central station companies by some form of concerted action, using funds that would otherwise be used for extensions to the local stations and funds derived from the additional revenues made possible by local interconnections in anticipation of the building of the main tie line.

AN INDUSTRIAL MOTION PICTURE THEATER

There has recently been put in operation in the Lynn, Mass., works of the General Electric Company a fully equipped motion picture theatre. The auditorium is 130 feet in length and 20 feet wide and will accommodate 390 persons. At one end is a thoroughly modern projection room, in which are installed 4 first-class picture machines of different makes. Screens of various kinds are provided. A permanent screen at the end of the hall is supplied for "movie" shows and a movable screen for experimental purposes can be placed anywhere so as to obtain different lengths of throw and different sizes of pictures. A slot opening is provided in the wall so that this can be removed from the room when it is not in use.

This theater and equipment were installed primarily for the purpose of conducting experiments in connection with the development of the Mazda incandescent lamp and auxiliary equipment for motion picture work, and every facility is provided for obtaining tests on different types of devices, optical systems, etc. Direct-current and alternating-current arcs may be used in comparison with the Mazda equipment. By the aid of the movable screen above referred to any distance of throw up to 130 feet and any size of picture can be obtained so that the conditions encountered in any ordinary theater can be duplicated.

The screen mounted permanently at the end of the room is what is known as the "crystal-bead screen" and consists of a canvas spread with flat white paint in which are embedded a large number of very small glass beads. This provided a very brilliant effect, much brighter than can be obtained with the ordinary type although it is limited to long, narrow halls. The movable screen, on the other hand, is of the ordinary flat white paint variety.

The walls are finished in dull buff and deep browns and a number of life-sized paintings of well-known film artists are hung on the walls.

Although the theater was primarily installed for experimental purposes and is said to be one of the best in the country for this purpose, the facilities are available at any time out of regular working hours, for showing other films for educational and entertainment purposes for any of the organizations connected with the General Electric Company.

The entire outfit has passed inspection by the State authorities, and two of the employes of the department which is handling this development are regularly licensed as motion picture operators. A number of organizations of employes have already taken advantage of this opportunity and interesting meetings are held in this theater noon hours and evenings. As soon as details can be worked out it is expected that employes in each factory will be presented with tickets for certain occasions when they may bring their wives and children. Only the best pictures possible to obtain will be shown and the show will be free to the employes.

The use of the motion picture for educational purposes is only in its infancy, yet there are many films of this character that can be obtained, and with the equipment available there is no reason why many entertainments cannot be given in such places for the instruction and entertainment of employes.—*Safety Engineering.*

THE WHITE SULPHUR SPRINGS CONVENTION

The 36th Annual Convention of the A. I. E. E. held at the Greenbrier, White Sulphur Springs, June 29 to July 2, proved to be one of the most interesting and enjoyable conventions of recent years. The location was ideal, and the natural beauty of the West Virginia mountains lent added attraction to the abundant facilities provided for all kinds of outdoor recreations. Motoring, horseback riding, swimming and walking over the numerous mountain trails, were freely indulged in by a large number of those in attendance and the golf links and tennis courts were well patronized.

The hotel is well adapted for convention purposes, and the White, in which the technical sessions were held afforded more than usual facilities for the meetings. The meeting rooms were large and well ventilated, opening onto a spacious veranda, and proved comfortable even on the hottest days. The hotel management endeavored in every way to make the meeting a success and greatly aided the convention committee in its efforts to provide for the pleasure and entertainment of all in attendance.

The total attendance of members and guests was 314, including 60 ladies. Twenty-six states and Canada were represented.

The general policy which was adopted in the preparation of the program, of holding the technical sessions in the mornings and leaving all the afternoons and two of the evenings for events arranged by the Convention Committee, consisting principally of contests and other forms of entertainment, including several social events specially provided for the ladies, was favorably commented upon by practically all in attendance, and afforded desirable opportunity for informal discussions, renewal of old associations, and development of acquaintanceship—all of which is now well-known to be among the greatest advantages of gatherings of professional men.

The five technical sessions, held one on each morning and one Thursday evening, were well attended and in spite of a rather crowded program the papers were generally well discussed at considerable length. In order to afford an opportunity to speak for all who wished to discuss the papers, the Meetings and Papers Committee prepared a schedule in advance of the convention, assigning a definite time to which each author and discussor was limited in presenting his remarks. This time limit was adhered to during all the sessions with the result that all who wished to speak could do so. This procedure had the added advantage of improving the discussions which were generally concise and to the point.

The conference of Section delegates, held on Wednesday evening was temporarily adjourned to give the delegates opportunity to attend the piano recital by Prof. Karapetoff, after which the meeting reconvened and discussed questions of Institute policies in which practically every one present took part.

The Board of Directors of the Institute held its regular June meeting on Wednesday afternoon, June 30, as referred to elsewhere in this issue.

The Meetings and Papers Committee held a meeting at luncheon on June 30, for the purpose of formulating plans for future Institute meetings.

Members of several other committees of the Institute held numerous informal conferences during the convention.

TECHNICAL SESSIONS

The first session was opened on Tuesday morning by President Townley who called the meeting to order and after a few words of welcome proceeded to deliver his presidential address on "An Engineering Analysis of the Labor Problem", which is published elsewhere in this issue.

President-elect Berresford was then introduced and spoke briefly acknowledging the honor of his election.

The annual reports of the Technical Committees were then presented. These were discussed by President Townley, William A. Del Mar, H. R. Summerhayes, Selby Haar, Philip Torchio, Dugald C. Jackson B. C. Dennison E. H. Martindale, D. W. Roper, Fred G. Dustin, A. W. Berresford, Ernest V. Pannell, C. A. Copeland, I. Melville Stein, H. L. Hibbard, W. I. Middleton, R. A. Beekman, John Murphy, and Arthur Parker. The members of the committees who presented the reports answered some of the questions raised.

The second session was called to order on Wednesday morning by President Townley. Nine papers were scheduled for this session consisting of two groups classified under the heads of "Electrical Machinery" and "Miscellaneous Papers". All of the papers were read by their authors except Mr. Lamme's paper which was presented by Mr. Newbury.

These papers were discussed by W. J. Foster, F. D. Newbury, R. B. Williamson, Wm. F. Dawson, Robert Treat, Philip Torchio, James Lyman, B. L. Barnes, A. S. Loizeaux, S. R. Bergman, C. J. Fechheimer, S. L. Henderson, C. L. Fortescue, A. E. Kennelly, Joseph Slepian, L. W. Chubb, F. W. Peek, Jr., W. H. Pratt, with closing remarks by the authors. There were also written discussions by R. E. Hellmund and C. W. Kincaid, jointly, and by R. M. Spurck.

Vice-President Wills Maclachlan presided during a part of this session.

The third session was held Thursday morning with Mr. D. W. Roper, Chairman of the Protective Devices Committee presiding. Four papers were presented at this session on the subject of protective devices. Mr. B. G. Jamieson presented the paper for Mr. Schuchardt and Mr. R. E. Doherty presented the paper by Dr. Steinmetz. Mr. F. H. Kierstead and Mr. H. B. Dwight presented their own papers in abstract.

These papers were discussed by A. E. Bauhan, Robert A. Hentz, Dugald C. Jackson, Philip Torchio, James Lyman,

C. J. Holslag, B. G. Jamieson, C. L. Fortescue, R. E. Doherty, V. Karapetoff, Henry R. Woodrow, E. G. Merrick, J. A. Johnson, D. W. Roper, H. R. Summerhayes, J. F. Peters, A. E. Kennelly, H. B. Dwight, A. Nyman, Joseph Slepian and F. H. Kierstead.

The usual closures by the authors were made.

The fourth session was called to order Thursday evening by Vice-President A. M. Schoen, who occupied the chair. There were 19 papers scheduled for presentation at this session, 8 of of which were devoted to Electric Welding and 11 to a symposium on the proper definition of polyphase power factor. It became apparent after the first two papers had been abstracted that the time would not permit of the presentation of all the papers, even in abstract, so by action of the meeting the papers were presented by title only and immediately thrown open for discussion.

The papers were discussed by H. L. Unland, R. W. Owens, A. M. Candy, C. J. Holslag, William O. Noble, William A. Turbayne, Douglas F. Miner, F. V. Magalhaes, F. C. Holtz, V. Karapetoff, C. J. Fechheimer, Robert D. Evans, A. E. Kennelly, Philip Torchio, H. Bristol Dwight, W. H. Pratt, George A. Sawin, J. R. Craighead and C. L. Fortescue.

There was a written discussion by G. G. Post, and closures by several of the authors.

The fifth and last technical session of the convention was held Friday morning, Mr. Philip Torchio, chairman of the Power Stations Committee, presiding. Six papers were presented at this session, all on the general subject of exciter systems for central stations.

After presentation in abstract the papers were discussed by W. F. Sims, E. G. Merrick, William F. Dawson, A. Karapetoff, W. J. Foster, R. E. Doherty, C. J. Fechheimer and James Lyman.

SECTION DELEGATES CONFERENCE

The conference of Section Delegates was held Wednesday evening. Thirty of the Sections of the Institute were represented at the convention by delegates, as provided in the Institute constitution. Following is a complete list of the delegates present:

Section	*Delegate*
Atlanta	A. M. Schoen
Baltimore	J. B. Whitehead
Boston	W. I. Middleton
Chicago	A. F. Riggs
Cleveland	B. W. David
Denver	H. B. Dwight
Detroit-Ann Arbor	G. E. Lewis
Fort Wayne	C. I Hall
Indianapolis-Lafayette	D. C. Pyke
Ithaca	V. Karapetoff
Los Angeles	C. A. Copeland
Lynn	A. K. Warren
Madison	C. M. Jansky
Milwaukee	H. P. Reed
Minnesota	F. G. Dustin
New York	H. A. Pratt
Philadelphia	C. E. Clewell
Pittsburgh	B. C. Dennison
Pittsfield	R. E. Wagner
Portland, Ore.	E. F. Whitney
Providence	R. W. Eaton
St. Louis	G. A. Waters
San Francisco	L. S. Ready
Schenectady	C. S. Van Dyke
Seattle	W. T. Batcheller
Toronto	A. B. Cooper
Spokane	J. E. E. Royer
Urbana	Morgan Brooks
Utah	H. T. Plumb
Washington, D. C.	A. C. Oliphant

The officers present were: President Calvert Townley, New York; Vice-Presidents A. M. Schoen, Atlanta, N. A. Carle, Newark, N. J., Wills Maclachlan, Toronto; Managers Charles S. Ruffner, New York, Charles Robbins, Pittsburgh, E. H. Martindale, Cleveland, Wm. A. Del Mar, New York, W. I. Slichter, New York, F. D. Newbury, Pittsburgh; Secretary F. L. Hutchinson, New York.

Prior to the meeting, all the Sections of the Institute had been communicated with by the Program Committee of the Sections Committee, and requested to suggest subjects for discussion at this conference. Probably because of the fact that the needs of the Sections, as well as the policies of all other Institute activities, had been so thoroughly considered jointly by the Section Delegates and the Development Committee last year and practically all recommendations made at that time had been, or are now being, put into effect, the responses were rather limited; and therefore, the Program Committee arranged for only one meeting of the delegates, to be held on Wednesday evening, thus allowing two full days prior to the meeting for the delegates to meet, become acquainted, and discuss informally before the official conference the various matters in which they were particularly interested.

The subjects thus officially suggested and placed upon the program were as follows:

(1) Geographical divisions as provided in recent constitutional amendment—how many should there be? And how should the limits be defined?

(2) Territorial limits of Sections—should they be modified; and if so how?

(3) Financial support of the Sections from the parent body. Present basis is $100 flat appropriation per section plus $1.25 per member in the Section.

(4) Grades of membership—should there be more or less? And if so what should be the qualifications?

(5) Membership application references. Suggestion has been made that the record of applicant should accompany the forms.

(6) Classification of the field of electrical engineering. *i. e.*, classifying the members of the Institute according to the branches of the industry in which they are specializing, and so indicating this classification in the Year Book.

In the absence of Chairman Walter A. Hall of the Sections Committee, Senior Vice-President A. M. Schoen, of Atlanta, presided at the conference on Wednesday evening and briefly outlined the purpose of the meeting; then introduced President Townley, who, in a brief address, urged upon the delegates present the desirability of free discussion on any matters relating to Institute activities which they deemed of interest. President-elect Berresford then spoke briefly, calling attention to the fact that every recommendation made by the Section Delegates would, as had been the case in the past, receive the careful consideration of the Board of Directors.

Vice-President Schoen then presented for discussion the six topics as outlined above, upon which there was a very general discussion by all the delegates, officers, and others present, after which the meeting was thrown open to other topics. The meeting adjourned at 12:30 a. m.

The entire discussion was reported stenographically and an abstract of all the essential features will be prepared and printed in phamphlet form for distribution to the delegates and the officers of all Sections and of the Institute, and will also be available to any other members who are interested, upon application to the Secretary, at Institute headquarters, New York.

ENTERTAINMENT

The entertainment features of the Convention were especially attractive and were an enjoyable feature of a noteworthy Convention. Much credit is to be given to the capable work of the Convention Committee consisting of Messrs. John H. Finney, Chairman, Walter A. Hall, F. L. Hutchinson, Farley Osgood, Chas. Robbins, A. M. Schoen, and W. I. Slichter, assisted by a part of the "Rebel Brigade" headed by W. S. Lee of Charlotte, W. G. Claytor of Lynchburg, H. G. Scott of Charleston, W. Va., and others. Hotel arrangements were entirely adequate, the hotel management cooperating in every plan proposed for the comfort and entertainment of the Convention members and guests. The guests of the hotel were formally invited to participate in both the technical sessions

and in the entertainment features, and the response was so general that the various events were characterized by large attendance and many pleasant features.

The President's reception Tuesday evening had as a new feature the lady guests of the Convention in the reception line. The formal presentations were made by the Chairman of the Convention Committee and the plan made everybody promptly acquainted with the entire membership in attendance and made the dancing which followed very informal and enjoyable.

On Wednesday evening Professor Vladimir Karapetoff of Cornell University gave an interesting and brilliant piano recital in the Greenbrier Ball Room before a capacity audience. These annual recitals are a fixture of our Convention and always prove a noteworthy attraction.

Base Ball

In spite of the absence of several base ball champions of former conventions, including Farley Osgood and W. A. Hall, and while W. S. Lee was playing a match in golf, the annual base ball game was pulled off according to schedule on Thursday afternoon before a large crowd of enthusiastic rooters. The teams captained by Mr. H. P. Chase and Mr. B. W. David, were composed as follows

	AB	H	R		AB	H	R
Chase, P. H...... 1 b.	6	3	2	David, B. W...... 1 b.	4	2	1

Home Run, Nunamaker 3-base hits, David, Kyle

The afternoon was perfect—many brilliant plays were pulled off—notably the home run of Nunnemaker (who incidentally won thereby the prize for the longest hit)—the daring slide of H. E. Shedd into third—the classy pitching of Olson—the loyal rooting of Mrs. H. P. Chase—were all features of a historic event.

Teas

Teas for the ladies were held on Wednesday in the Spring Room of the Greenbrier, on Thursday afternoon after the ball game at the delightfully situated Kates Mountain Club, and on Friday afternoon in the Casino when prizes were presented. The latter event brought in many of the men and was a fitting windup of the formal Convention events.

Tennis

There were large entry lists for both singles and doubles in tennis, the tournament being very capably handled by Mr. G. A. Sawin of Newark. Men's singles were won by Mr. G. A. Sawin, runner up being Mr. W. Edwards. Men's doubles, finals of which were prevented by rain on Friday, were so far played as to enable a decision to be reached as to winners and prizes were awarded to Sawin and Summerhayes, with C. H. Wolfe and R. D. Evans as runners up.

Golf

Prizes for the various events, under the management of Mr. A. M. Schoen, were awarded as follows:

Low grass score—Mr. A. E. Knight.
Winner 1st 16—Mr. M. G. Kennedy.
Runner up—Mr. W. S. Lee.
Winner 2nd 16—Mr. R. H. Knowlton.
Runner up—Mr. A. C. Cooper.
Winner 3rd flight—Mr. M. McIver.

Mr. Kennedy's victory entitles him to have his name inscribed on the handsome Mershon Golf Trophy, which will become the property of the first person who succeeds in winning the golf tournament at two Institute Conventions. It has previously been won by Mr. A. M. Schoen of Atlanta, Mr. J. C. Mock of Detroit, Mr. E. W. Allen of Chicago, Mr. L. F. Deming of Philadelphia, and Mr. A. A. Brown of New York City.

Ladies Putting Contest

First—Mrs. R. C. Muir, Schenectady.
Second—Mrs. N. M. Garland, New York City.

Bridge Tournament

First—Mrs. W. S. Lee of Charlotte.
Second—Mrs. C. D. Hembold, Washington.
Consolation—Mrs. V. Karapetoff, Ithaca.

Special bridge prizes were awarded to:
Mrs. M. C. Olson of Schenectady.
Miss F. K. Cooke of New York City.
Mrs. T. F. Barton of Schenectady.
Mrs. A. R. Smith of Schenectady.

Hearts

Winner—Mrs. W. J. Foster.

PACIFIC COAST CONVENTION

Portland, Oregon, July 21-24, 1920

The Pacific Coast Convention of the A. I. E. E. was held at the Multnomah Hotel, Portland, Oregon, July 21 to 24. The registered attendance was 251; the various technical sessions and entertainment features were exceedingly interesting and profitable to all who attended and reflected great credit upon the members responsible for the arrangement, including Mr. E. F. Whitney, Acting Chairman and Mr. W. C. Heston, Secretary of the Portland Section; and the Chairmen of Committees as follows: General Convention Committee, R. M. Boykin, Arrangements Committee, J. E. Yates, Entertainment, R. F. Monges, Program, O. B. Coldwell.

Morning Session—July 21

Vice-President, John B. Fisken of Spokane presided at the opening session on Wednesday morning, July 21. Honorable George L. Baker, Mayor of Portland, extended a welcome on behalf of the City. Secretary Hutchinson made a brief address, at the close of which he stated that Mr. Fisken had agreed to accept an invitation from President-Elect Berresford to become Chairman of the Sections Committee of the Institute for the administrative year beginning August first. The announcement was received with unanimous approval.

Dr. C. E. Magnusson of the University of Washington, and Vice-President Elect of the Institute, then delivered an exceedingly interesting address relating to the memorable discoveries of Volta, Oersted, Ampere, Ohm, Faraday and Arago, underlying the progress that has been made in electrical engineering. He called attention to the fact that it was one hundred years ago to a day; namely, on July 21, 1820 that Oersted announced his remarkable discovery of the relation between the magnet and the electric current.

Mr. F. D. Weber called attention to the law now in force in Oregon, requiring registration of all who practise professional engineering in this state. He stated that until July 1, 1920, engineers possessing certain qualifications who were already practising had the privilege of registering without examination and, since that date all candidates were passed upon by an examining board. Engineers already registered include the following: Civil, 805; Mechanical, 178; Hydraulic, 157; Electrical, 119; Mining, 64; Metallurgical, 50; Structural, 36; Chemical, 14; Logging, 12; Naval, 11 and Fire Prevention, 2.

Technical papers were then presented as follows:

"Factors Controlling The Design and Selection of Suspension Insulators" by W. D. A. Peaslee, Consulting Engineer of the Jeffery-De Witt Insulator Company (presented by Mr. Peaslee).

"Unit Voltage Duties in Long Suspension Insulators" by Prof. Harris J. Ryan and Henry H. Henline of the Leland Stanford University (presented by Prof. Ryan).

Afternoon Session, July 21

The Presiding Officer at this session was Mr. E. F. Whitney Acting Chairman of the Portland Section.

The paper entitled "Electrical Characteristics of the Suspension Insulator at the Higher Voltages" by Mr. F. W. Peek, Consulting Engineer of the General Electric Company, Pittsfield, Massachusetts was presented by Mr. R. F. Monges, Portland.

The discussion on the three papers mentioned above was participated in by Messrs. J. B. Fisken, Spokane, M. T. Crawford, Seattle, E. R. Stauffacher, Los Angeles, L. C. Williams, San Francisco, G. E. Quinan, Seattle, W. A. Hillebrand, San Francisco, K. A. Hawley, New York, S. C. Lindsay, Seattle, L. Lauridsen, Portland, A. C. Pratt, Butte, C. P. Osborne, Portland, D. W. Proebstel, Portland, J. C. Clark, San Francisco, H. H. Schoolfield, Portland.

Morning Session, July 22

Mr. R. F. Hayward of Vancouver, B. C. presided at this Session and the following papers were presented by the authors:

"Electric Power Consumption on the Electrified Rocky Mountains and Missoula Divisions of the C. M. & St. P. Railway," by Mr. R. Beeuwkes, Electrical Engineer of the C. M. & St. P. Ry.

Discussion followed by Messrs. J. B. Fisken, Spokane, A. A. Miller, Seattle, G. E. Quinan, Seattle, Paul Lebenbaum, Portland, H. T. Plumb, Salt Lake City, S. C. Lindsay, Seattle, W. J. Davis, Jr., San Francisco, H. J. Ryan, Leland Stanford Univ., E. R. Cunningham, Portland, J. C. Clark, San Francisco, J. R. Read, Vancouver, B. C., R. M. Boykin, Portland.

"Bridge Methods For Alternating Current Measurements" by D. I. Cone, Pacific Telephone & Telegraph Company, San Francisco.

Discussion followed by Messrs: W. A. Hillebrand and R. W. Mastick of San Francisco; H. J. Ryan and J. C. Clark of Leland Stanford University; W. D. Scott and C. E. Magnusson of Seattle; H. V. Carpenter of Pullman.

Afternoon Session, July 22

Mr. G. E. Quinan, Chairman of the Seattle Section presided. A paper entitled "Sawmill Refuse, Powdered Coal and Oil Fuels" by Darrah Corbet of Chas. C. Moore & Company, Seattle, was presented by the author.

Discussion followed by Messrs.: L. T. Merwin, C. P. Osborn, J. H. Paulhemus, H. H. Schoolfield, of Portland; J. B. Fisken of Spokane, S. H. Graf of Corvallis, R. F. Howard, Vancouver, B. C., S. C. Lindsay and Ralph Galt, Seattle and W. A. Hillebrand of San Francisco.

Evening Session, July 22

Doctor C. E. Magnusson of Seattle, Vice President-Elect presided. A paper on "Application of Mild and Alloy Steels to High-Tension Suspension Lines" by L. R. O'Neill, Chief Engineer, Maryland Pressed Steel Company, Hagerstown, Md., was presented by Mr. W. D. A. Peaslee.

Discussion followed by Messrs. John B. Fisken of Spokane, R. W. Sorensen of Pasadena and S. C. Lindsay of Seattle.

INSTITUTE AFFAIRS

A general discussion on the subject of Institute welfare had been scheduled by the Convention Committee for this session. Secretary Hutchinson opned the discussion with a statement rgarding the present status of the principal activities of the Institute, including the actions that have already been taken relative to carrying out the recommendations made last year by the Development Committee and the Sections Delegates at the Lake Placid Convention in June, 1919.

An interesting discussion followed which was participated in by Messrs. L. T. Merwin, J. B. Fisken, C. E. Magnussen, G. E. Quinan, W. A. Hillebrand, R. W. Sorensen, J. C. Clark, H. T. Plumb, H. V. Carpenter, R. F. Hayward, W. A. Scott, H. H. Schoolfield and F. L. Hutchinson.

The session closed by the unanimous adoption of a resolution requesting the Board of Directors to give serious consideration to holding the 1921 Annual Convention in conjunction with the Pacific Coast Convention at Salt Lake City, Utah.

Friday Morning, July 23

Vice President, John B. Fisken presided. A paper entitled "Power Factor Correction of Distribution Systems" by D. M. Jones, General Electric Company, Schenectady, New York, was presented by the author.

Discussion followed by Messrs. J. E. Woodbridge, W. J. Davis, of San Francisco; R. F. Heyard of Vancouver, B. C.; Harris J. Ryan of Stanford Univ.; H. T. Plumb of Salt Lake City; C. A. Whipple of Seattle; O. B. Caldwell and L. T. Merwin of Portland.

The session closed with the unanimous adoption by the visiting members and guests of a resolution expressing their appreciation of the effective services of the officers, committees and members in providing for the comfort and entertainment of all in attendance at the convention.

Entertainment

On Wednesday evening, July 21 the members and guests were taken by the Portland members on an automobile trip over the Boulevards and through some of the beautiful Parks and residential sections of Portland and vicinity.

Thursday, July 22

Thursday afternoon there was a tea for the ladies at the Waverly Country Club, which was greatly enjoyed by the fifteen ladies present.

Friday, July 23

On Friday afternoon a Golf Tournament for the John B. Fisken cup resulted in a victory for Mr. C. L. Wernicke of Portland, who, thereby, is entitled to retain the cup until the next Pacific Coast Convention.

Friday afternoon was utilized by the majority of those in attendance to participate in a trip by automobile over the far and justly famed Columbia River Highway, after which the entire party, including the golfers, attended a banquet at the Crown Point Chalet on the Highway. About 165 members and guests attended. Mr. Whitney, acting chairman of the Portland Section, presided and Vice-Pres. John B. Fisken presented the golf prizes to Mr. Wernicke winner of the tournament and Mr. Whitney who had the low grass score. A brief address relating to effects of the work of the engineer on the social environment of the Pacific Coast States was given by Mr. W. H. Galvani of Portland. Dancing followed until a late hour when all returned to Portland after a most enjoyable evening and with many expressions of appreciation of the manner in which the officers and committees of the Portland Section had managed this and all other events of the Convention.

Saturday was utilized by many of the visiting members to inspect power plants and other places of engineering interest.

A. I. E. E. DIRECTORS MEETING

JUNE 30, 1920

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at The Greenbrier, White Sulphur Springs, W. Va., Wednesday, June 30, 1920, at 5:00 p.m.

There were present: President Calvert Townley, New York; Vice-Presidents N. A. Carle, Newark, N. J., Wills Maclachlan, Toronto; Managers W. A. Del Mar, C. S. Ruffner, W. I. Slichter, New York, E. H. Martindale, Cleveland, F. D. Newbury, Pittsburgh;Secretary F. L. Hutchinson, New York. Also President-elect Berresford, by invitation.

Upon recommendation of the Finance Committee monthly bills amounting to $17,372.94 were approved.

Chairman Slichter of the Meetings and Papers Committee reported that a special committee consisting of himself as chairman and Messrs. Charles E. Bonine, Carl Hering, F. B. Jewett, C. E. Skinner, and W. L. Upson, had been appointed to make arrangements for the October meeting in Philadelphia, which is to be devoted largely to addresses commemorating the one-hundredth anniversary of the electrical discoveries of Oersted, Ampere, Arago and Davy.

Reports were presented of meetings held on June 7 and 21, 1920, of the Board of Examiners; and the actions taken on applications at those meetings were approved. Upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 80 students were ordered enrolled; 449 applicants were elected to the grade of Associate; 21 applicants were elected to the grade of Member; 59 applicants were transferred to the grade of Member; 18 applicants were transferred to the grade of Fellow.

Reports of the various subcommittees of the Industrial and Domestic Power Committee, consisting principally of outlines of plans of these subcommittees for the preparation of monographs relating to applications of electricity in the various industries covered by the subcommittees, were presented; and it was voted to refer these reports to the Publication Committee for consideration of a plan of procedure in publishing these monographs and similar technical information that may be prepared by other committees of the Institute, including the Marine Rules recently formulated by the Marine Committee.

Upon the recommendation of the Sections Committee, a request for authority to organize an Institute Section at Cincinnati, Ohio, was granted.

Dr. W. R. Whitney, whose term as one of the three representatives of the A. I. E. E. on the Engineering Division of the National Research Council expired June 30, 1920, was reappointed for a term of three years ending June 30, 1923.

An invitation from the American Engineering Standards Committee for the Institute to act with the Bureau of Standards as joint sponsors in the formulation of a safety code for lightning protection, was accepted; and it was voted to authorize the President to appoint a committee of two or three members of the Board to confer with the Bureau of Standards regarding the matter, including the question of organization of a Sectional Committee to carry on the work as required by the Rules of Procedure of the A. E. S. Committee.

President Townley reported orally upon the conference held in Washington, June 3-4, 1920, of representatives of more than seventy engineering societies, including the Institute, and which resulted in a recommendation that these societies join a proposed body to be known as "The Federated American Engineering Societies", the governing body of which will be "The American Engineering Council". Mr. Townley outlined the main features of the constitution as adopted at the Washington meeting and as published in the July issue of the Institute JOURNAL. The following resolution was unanimously adopted:

RESOLVED, that it is the sense of the Board that the A. I. E. E. should join the Federated American Engineering Societies, but that as there is a small attendance at this meeting and a new Board will be constituted commencing with the administrative year on August 1, action be deferred until the August meeting of the Board; and that in the meantime the matter be referred by letter to the members of the incoming Board, with a request that they give careful consideration to the matter and be prepared to act at the next meeting.

The Secretary called attention to the constitutional amendments recently adopted providing for the division of the entire membership of the Institute into districts and the election of a vice-president from each district, and recommended that a special committee be appointed. It was voted that the President be authorized to appoint a committee to consider the division of the membership of the Institute into districts in accordance with the constitutional amendments adopted May 21. and to make recommendations to this Board regarding the number of districts that should be established and the territorial limits of each district.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

At the conclusion of the meeting, the Board expressed its appreciation of the faithfulness and marked ability with which President Townley has administered his office during the past year. President Townley responded briefly, thanking the members of the Board for their hearty cooperation during the year and expressing his appreciation of the opportunities which he had enjoyed of being associated with the members of the Board in the work of the Institute during the past year.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

For the Sixth National Exposition of Chemical Industries which will be held in Grand Central Palace, New York, September 20 to September 25, inclusive, there are being arranged the biggest symposiums on Chemical Engineering ever carried out in this country. Up to the present four symposiums have been scheduled. One will be on Fuel Economy, one on Materials Handling, one under the general head of Chemical Engineering, and another on Industrial Management. Moving pictures have played a big part in previous chemical expositions but this year there will be a series of films which will far surpass anything before attempted. The majority of these are absolutely new, in fact some are still in the process of making.

With 370 applications for exhibits already booked, the Sixth National Exposition of Chemical Industries will be on a record breaking scale. The exposition has become an institution in the United States and each year finds new displays that further reveal the ingenuity and cleverness of this country's chemists.

There will be a wide range of exhibits this year. The fact that the exposition has been divided into sections has caused greater interest than ever and the Materials Handling Division and the Fuel Economy Division, both of which will be new this year, have attracted many large concerns.

With the majority of the exhibits tending along the lines of progress and economy it is evident that a visit to the exposition will benefit manufacturers and business men. Impressions not gained elsewhere, and valuable in the future will be stowed away, for a glance into the inside of chemistry has been known to bring improved conditions in many industries and manufacturing plants.

ANNUAL MEETING OF TELEPHONE PIONEERS OF AMERICA

The Seventh Annual Meeting of the Telephone Pioneers of America will be held at Montreal, Canada, on September 10th

and 11th, 1920, with headquarters at the Windsor Hotel. The Bell Telephone Company of Canada will provide entertainment for the members and their families on the 11th. For the trip, special accommodations have been arranged from New York and other points, providing for a side trip to Au Sable Chasm on the return, with a steamer trip through Lake George.

THE FEDERATED AMERICAN ENGINEERING SOCIETIES

One of the outstanding features of the Organizing Conference in Washington, June 3-4, 1920 was the enthusiastic interest and cooperation exhibited by the delegates of the local, state and regional engineering organizations. It is not surprising therefore that these organizations should be among the first to apply for membership in the Federated American Engineering Societies. In this connection it is interesting to note that the Technical Club of Dallas, at its meeting of June 22d made application for membership and at the same time filed its claim as being the first local organization to apply.

At the Annual meeting of the American Institute of Chemical Engineers held in Montreal June 28-29, 1920, the question of the Institute becoming a member of the Federated American Engineering Societies was favorably discussed and referred to the Council for consideration at its meeting on July 25th, at which time definite action will be taken. In the discussion the opinion was expressed that the Institute should be a member of this organization and if its finances would not permit this, that members should be assessed the necessary amount.

The report of the delegates to the Washington Organizing Conference was read at the meeting of the Board of Directors of the American Institute of Electrical Engineers at the Annual Convention at White Sulphur Springs, W. Va., June 30th and the following resolution adopted:

RESOLVED, That it is the sense of this Board that the A. I. E. E. should join The Federated American Engineering Societies, but that as there is a small attendance at this meeting and a new Board will be constituted commencing with the administrative year on August 1, action be deferred until the August meeting of the Board and that a letter be sent the members of the incoming Board, with a request that they give careful consideration to the matter and be prepared to act at the next meeting.

The report of the delegates to the Washington Organizing Conference was read at the meeting of the Board of Direction of the American Institute of Mining and Metallurgical Engineers on June 25, was favorably discussed and referred to the Finance Committee to devise and report on means of meeting the financial requirements.

The report of the delegates to the Washington Conference representing the American Society of Civil Engineers will be presented at the Annual Convention of the Society, at Portland, Oregon, August 10-12, 1920.

In the aftermath of the Washington Conference there has been considerable discussion of the new organization and a number of incorrect statements have been made; one of these is that "During the war, technical men observed the fact that many engineering problems required the joint action of the technical societies. This requirement was met by the formation of Engineering Council. Now the Organizing Conference proposes new organization." This is not correct, as it has been repeatedly pointed out that the work of The Federated American Engineering Societies will be administered by the American Engineering Council which will succeed the present Engineering Council. This procedure received the approval of Engineering Council at its meeting on October 16, 1919, when it endorsed the "General plan for a national engineering council as outlined by the Joint Conference Committee of the Founder Societies."

It has also been suggested in the technical press that "no specific business is as yet outlined for action by the Council" that "The federated society is so completely nebulous that one cannot commend or condemn it" and it will be sometime before the new organization will begin to function. As a matter of fact the Organizing Conference at the closing session on June 4 adopted the following resolution:

RESOLVED, That it is the sense of this Organizing Conference that the Joint Conference Committee should be entrusted with making provisions for putting the conclusions of this conference into effect and that Engineering Council be requested to carry on its work until the new organization has been established, and by all proper means to further the program of the new organization. The Conference further recommends to the contributing societies that they continue supplying the funds required by Engineering Council until its work is taken over by the new organization.

Engineering Council at its meeting of June 17, 1920 unanimously adopted resolutions complying with this request. The resolutions were published in the July JOURNAL.

The action of Engineering Council in accepting the invitation of the Organizing Conference means that the activities of Engineering Council which are those to be undertaken by The Federated American Engineering Societies, will be continued without interruption until the American Engineering Council is prepared to take up the work.

The statement that this new organization "is completely nebulous" is refuted by the fact that the Organizing Conference in Washington adopted a complete constitution and by-laws to govern the organization which came into active existence when The American Society of Mechanical Engineers applied for membership immediately following their adoption, and at which time assurances were given that the Detroit Engineering Society and the American Institute of Electrical Engineers had taken, or would take, similar action.

To this nucleus must be added the Technical Club of Dallas so that The Federated American Engineering Societies has come into active existence and the first meeting of its governing body will be held probably in November of this year.

The organization is to deal with what are commonly known as welfare or non-technical matters. It is not a social organization; it is not an organization of individual members. As its title indicates, it is a federation of societies with whose autonomy and activities it in no way interferes. It does not create a new technical society but it will succeed the present Engineering Council and will be more comprehensive as to scope and membership.

The Federated American Engineering Societies will not in any sense be a competitor of any existing organization. Its success will depend upon the whole hearted support given by the individual engineers and allied technologists of this country through the respective engineering and allied technical societies with which they are identified. The unanimity of opinion in which there was no dissenting vote, with which the following fundamental resolutions of the Washington Organizing Conference were adopted indicated that the psychological moment had arrived for an organization of this character and this fact assures its success:

RESOLVED, That it is the sense of this Organizing Conference that an organization be created to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions.

RESOLVED, That it is the sense of this conference that the proposed organization should be an organization of societies or affiliations and not of individuals.

SOME EXPLANATIONS BY THE JOINT CONFERENCE COMMITTEE

The object of The Federated American Engineering Societies as declared in its Constitution, and as has been repeatedly stated,

> Shall be to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions.

Notwithstanding this, the statement is repeatedly made that the organization does not deal with the interests of the individual engineer and of the allied technologists. The purpose of the organization is that of service first to the nation, state and community, and second, to the profession which obviously must include the interests of the individual. While it is true that it does not deal with the interests of the engineer and technologist as does a labor union for its member, nevertheless its work will do more ultimately to advance the interests of the individual than a labor union could possibly do, because the advancement of the profession through a greater recognition by the public of the engineer and allied technologist, and the greatly increased solidarity and higher standards of these professions must unquestionably work for their ultimate good.

Not a New Organization

The Joint Conference Committee, among others, has referred to The Federated American Engineering Societies as a "new" organization. This is not strictly correct. While the name is new, the organization will be a successor to the existing Engineering Council, whose work will be amplified and carried on on a much more extended plan as to scope and membership.

How and Why the Name was Selected

There has been considerable comment on the name of the new organization. Probably no detail caused the Committee on Constitution and By-Laws of the Organizing Conference, more serious thought than the question of a suitable name. The purpose was to secure a short title that could readily be used, and many suggested names were rejected for good and sufficient reasons. The Committee decided that the name of the organization should be indicative of its character, based on the fundamental resolution of the Organizing Conference, that it should consist of societies and not of individual members. The words "Association," 'Confederation," "Federation," and others were suggested and considered and all were rejected and finally as a compromise the word "Federated" was unanimously agreed to. In view of the fact that other countries are looking with interest on this movement with the probability that there will be similar organizations formed in those countries, it was felt desirable that some distinctive name should be given the organization in this country, and so the word "American" was inserted. Objection to this was made on the ground that this country is the "United States of America" but the answer was that the soldiers of this country fought in Europe as "The American Expeditionary Forces" and have been internationally so recognized. It was thought undesirable to use so long a name as Engineering and Allied Technical Societies especially in view of the fact that engineering as defined in the preamble of the Constitution is an all inclusive word, and it was, therefore, decided to use only the word "Engineering" in the title. Hence the name "The Federated American Engineering Societies."

It is probable however, that when the organization begins to function it will be referred to rarely as The Federated American Engineering Societies but will be called the American Engineering Council which is the executive body of the organization.

Basis of Representation

There seems to be difficulty in understanding what the basis of representation should be where a state organization exists and where there are also strong local organizations and affiliations. The Constitution provides that a state council or organization, representative of the engineers and allied technologists in the state, can be represented on the American Engineering Council on the basis of all the engineers and allied technologists in the state. If however, there exists a strong local organization or affiliation which elects to have its own representative or representatives on the Council then the state council or organization is entitled to representation on the basis of all the engineers and allied technologists in the state, less the engineers and technologists that are to be represented through their local organization or affiliation. This will not prevent the local organization or affiliation from participating in the work of the state council or organization in the consideration of matters affecting the state only.

No Provision for Dues

The Joint Conference Committee has received several letters inquiring as to the provisions for dues. The Constitution and By-Laws provide for funds contributed by the Member-Societies for the support of The Federated American Engineering Societies. Inasmuch as it would be unreasonable for a small local society to pay as large a contribution as a national society the Constitution provides that the contribution shall be on the basis of the number of members in the organization at the rate of \$1.50 per member for national societies and \$1.00 per member for local, state and regional organizations or affiliations. The individual, therefore, does not directly pay any dues but the Member-Society of which he is a member contributes to the support of The Federated American Engineering Societies on a per capita basis of its membership. It, therefore, follows that any one who is a member of several organizations which hold membership in The Federated American Engineering Societies will be counted in the total membership of each Society as a basis of its contribution.

Organization Not Cumbersome

It has also been stated that "the machinery proposed is somewhat elaborate and appears to be cumbersome and expensive." The Joint Conference Committee can see no basis for this statement. The By-Laws provide that

> Any Society or organization of the engineering or allied technical professions whose chief object is the advancement of the knowledge and practise of engineering or the application of allied sciences and which is not organized for commercial purposes, is eligible for membership.

The Federated American Engineering Societies will function through the American Engineering Council which will meet either annually, or bi-annually, as it will determine. This American Engineering Council will consist of representatives from the Member-Societies on the basis of one representative for from 100 to 1000 members and an additional representative for each additional 1000 members or major fraction thereof. From this body of representatives will be formed an Executive Board of thirty, consisting of six officers and twenty-four other members selected in part fom the national societies and the remainder from the local, state or regional organizations or affiliations. The plan reported by the Committee on Constitution and By-Laws provided that the representation on the Executive Board should be based on the ratio of the total number of members in the national societies to the total number of members in the local, state and regional organizations or affiliations. The Organizing Conference however changed this to the ratio of the number of representatives from the national societies to the number of representatives from the local, state and regional organizations or affiliations, on the American Engineering Council. This Executive Board will meet monthly or as often as may be found to be necessary to properly transact the business of The American Engineering Council. There will be an executive officer who will also be the secretary of these bodies and who will be entrusted with carrying out their instructions.

As a matter of fact, the American Engineering Council thus

created is less cumbersome or unworkable than the present Engineering Council; furthermore it has the distinct advantage of being more democratic and broader in its scope and membership.

Organization Conservatively Financed

As to the statement that the organization is expensive, it is pointed out that on the basis of the present membership of Engineering Council the income from the contributions provided in the Constitution of The Federated American Engineering Societies would be about $75,000. At no time in the history of its existence has the budget of Engineering Council exceeded $50,000. Provision is made, however, that

The Executive Board shall, whenever practicable, provide for the whole or a part of the expense of members of or representatives attending its own meetings and those of the Council.

On the basis of past experience, it is estimated that if the expenses of all the representatives on American Engineering Council and of the members of its Executive Board were paid to each meeting of these bodies, there would be involved an annual expense of about $25,000. The purpose of these expenditures was to secure a full attendance of the representatives of The American Engineering Council and on the Executive Board, especially during the earlier years of the organization. As will be noted in the excerpt from the Constitution the expenses of representatives of the Council and members of the Executive Board will be provided from such funds as may be available. If, in the judgment of the Executive Board, this money should be required for more urgent work the expenses of the representatives and members would not be provided for. It seems to the Joint Conference Committee that it would be highly desirable to have sufficient funds to pay the expenses of this representative body of men who contribute their time for the good of the engineering and allied technical professions. The payment of these expenses is the only part of the organization that can be said to be expensive.

Organization Democratic Not Autocratic

It has also been stated that the form of organization that has been set up is "autocratic, not democratic."

If a democratic organization is taken to mean one in which its constitutents have a voice in its affairs then the Federated American Engineering Societies is truly a democratic organization. Member-Societies of this organization are represented on the American Engineering Council which has full power to control and to direct the activities of the American Engineering Council and of its Executive Board and can determine whether it is necessary for the former to meet annually, bi-annually, or tri-annually, or how frequently the latter shall meet.

The Opportunity

The Joint Conference Committee is unqualifiedly of the opinion that an opportunity has been created for bringing about a solidarity of the engineering and allied technical professions that has never heretofore been available and that the success of the movement will depend on the whole-hearted support of each American engineer and of each technologist, who, if determined that this movement shall succeed, will obviously not bother with the details or the form of organization, in his efforts to secure the end desired.

A NEW FRENCH PUBLICATION

The publication of a new review of wireless telegraphy, entitled *Radioelectricite*, will be of interest to technical men as well as to the general public. *Radioelectricite* has been constituted in France by highest men in science and industry, and for its technical part appeals to the most eminent scholars or men of genius. Information regarding the publication may be addressed to 12, Place de Laborde, Paris, France.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

ABSTRACT OF NEW YORK LAW FOR LICENSING OF PROFESSIONAL ENGINEERS AND LAND SURVEYORS*

Effective May 14, 1920

Present practitioners must obtain licenses within 2 years

ADMINSTRATION: In hands of a board of five licensed engineers appointed by the regents of the University of the State of New York.

APPLICATION FOR CERTIFICATE: Must be made on prescribed form to Regents of the University of the State of New York, Albany, New York.

PROFESSIONAL REQUIREMENTS: Law covers all those practising or offering to practise professional engineering or land surveying.

Experience without Degree. To practise Engineering: 6 or more years of active professional engineering work, one of which shall have been in responsible charge, of a character satisfactory to the board. To practise Land Surveying: 4 or more years of active engagement in land surveying work of a character satisfactory to the board.

*Engineering Council does not guarantee the legal accuracy of this abstract.

Educational Allowance. Each two years of study of engineering in a school of engineering of standing satisfactory to the regents considered equivalent as to one year of active practise.

Society Membership. No provision covering membership in a National Engineering Society.

GENERAL REQUIREMENTS: Citizenship of United States. To practise Engineering: not necessary. To practise Land Surveying: necessary,—or a declaration to become a citizen.

Age. At least 21 years.

Miscellaneous. Must be of good character and repute. To practise Land Surveying, must speak and write the English language.

EXAMINATIONS: If evidence presented in application does not appear to board conclusive or warranting issuance of a certificate, applicant may present further evidence, which may include the result of a required examination.

Nature. Not prescribed.

Frequency. Not prescribed.

FEE: For certificate to practise Engineering or Land Surveying—$25.00

For certificate to practise both Engineering and Land Surveying—$35.00

If issuance of certificate be denied, fee shall be returned.

EXPIRATIONS AND RENEWALS: No provisions.

PUBLIC WORK: Two years after act takes effect, no county, city, town or village, or other political sub-division shall engage in construction or maintenance of any public work involving professional engineering or land surveying for which plans, specifications and estimates have not been made by, and construction and maintenance supervised by, a licensed engineer or land surveyor, provided contemplated expenditure for completed project does not exceed $2000.

SEALS: Each licensee may obtain a seal of design authorized by board, bearing licensee's name and the legend "licensed professional engineer" or "licensed land surveyor". Plans, specifications, plats and reports may be stamped with said seal.

EXEMPTIONS: See also "Reciprocity".

Offering to Practise by non-resident.

Employees of Licensed Practitioners. Employees of licensed engineers or licensed land surveyors, so long as practise does not include responsible charge of design or supervision as principal.

Contractors and Superintendents. Not covered by this law.

Federal, State and Municipal Employees. Employees of state or any political sub-division are exempted from the time act becomes effective only until the then existing term of office expires. Officers or employees of United States entirely exempt.

Corporations or Partnerships may engage in the practise of engineering or land surveying provided person or persons connected with such corporation or partnership in charge of design or supervision which constitutes such practise is or are licensed. Same exemptions as apply to individual apply to corporations and partnerships.

Overlapping Duties. Engineers not prohibited from making land surveys essential to engineering projects.

RECIPROCITY: Non-Resident Practitioner may practise in this state, provided he is legally qualified for such professional service in his own state or country, where the necessary qualifications for which meet the requirements of the board of regents. May be granted a certificate upon payment of the required fee if he holds a like unexpired certificate from another state or territory in the United States in which the requirements for license or registration are of a standard satisfactory to the board.

New Resident. Provided he has filed application for license and has paid required fee, may practise for such reasonable time as the board requires in which to consider and grant or deny application.

REVOCATION OF CERTIFICATE: The regents may revoke a certificate for cause only after a hearing at which the accused has the right to be represented by counsel, to introduce evidence and to examine and cross-examine witnesses.

PENALTIES: Any person who, after this act has been in effect 2 years, is not legally authorized to practise and shall so practise or otherwise violate its terms shall be deemed guilty of a misdemeanor and shall for each offense of which he is convicted be punished by a fine of not less than $100 nor more than $500, or by imprisonment for 3 months or both by fine and imprisonment.

LEGISLATIVE INFORMATION: Law is Article IV-A of Chapter 25, Laws of 1909.

Approved May 14, 1920. Introduced into Senate, No. 1104, by Mr. Ferris, March 17, 1920.

Article VII-A, Chapter 25, Laws of 1909 applies to registration of architects. Laws of 1915, Chapter 454.

PAYMENT FOR ESTIMATING

October, 1919, the American Institute of Architects, Engineering Council and Associated General Contractors of America, appointed three conferees each, to discuss the matter of payment for estimating. These conferees agreed upon a report which was submitted to their respective organizations under date of February 17, 1920, and has since been under consideration by them. Engineering Council at its meeting June 17 adopted the conclusion in a report of a special committee to which the report of the conferees had been referred as follows:

Whenever in the execution of work, competitive bids are asked for on detailed plans and specifications, those invited to bid should be provided with such an estimate of the quantities involved in the work as the surveys, plans and specifications permit to be made. The intent of this requirement is that a single estimate of quantities should be made by or for the engineer, architect, or other representative of the owner, so that each separate bidder will not be put to the expense of making up a separate schedule of estimates. This latter practise not only means a needless waste in the carrying on of contract work, but also discourages bidders and causes needless repeated handling of official plans and specifications in making up separate schedules of estimates.

ENGINEERING FOUNDATION

AN AMERICAN HYDRAULIC LABORATORY

Certain engineers have recently proposed an endowed American Hydraulic Laboratory. There are many needed contributions to hydraulic engineering and the underlying science which can best be made by a laboratory with sufficient resources. Numerous problems relating to power development, water supply, irrigation, sewerage, river improvement and other practical applications of hydraulics await solution by the work of competent experimenters in such a laboratory.

In Engineering Foundation there exists the instrumentality for bringing into existence such a laboratory as is suggested. To the limit of its small resources Engineering Foundation during the past year supported Mr. Clemens Herschel in experiments on weirs, which resulted in an improved form of weir and a simple straight line formula. Engineering Foundation Board is thoroughly competent to receive and administer endowment funds in any amount, including those which might be especially designated for an American Hydraulic Laboratory. Furthermore, the Foundation could undertake the establishment and management of such a laboratory and could publish, through the journals of its supporting societies, the technical press and its own bulletins, the results of the experimental work.

Instead of creating a new laboratory it might be found advisable for Engineering Foundation, if funds should be provided, to serve as an American Hydraulic Institute. The Institute could enlarge the usefulness of the existing hydraulic laboratories of the universities, the Government and the industries by directing experimenters and allocating problems to the laboratory best equipped for each specific project undertaken. It could contribute to the support of the experimenter and, if existing facilities were not adequate, could improve the facilities in the laboratory selected for the work.

As the instrumentality of its Founder Societies, Engineering Foundation is ready in this respect to serve the Profession and the industries connected with hydraulic engineering, and to apply the generous gifts of individuals or corporations to the needs of the Profession and these industries.

INTERSTATE COMMERCE COMMISSION NEEDS ENGINEERS

The United States Civil Service Commission states that the Interstate Commerce Commission is making every effort to expedite the valuation of common carriers. The importance of hurrying this work is evident, in view of the law which provided for the return of transportation properties to private

control and which specifies that the Interstate Commerce Commission shall adjust rates so as to insure a fair return upon the aggregate value of the railway property of carriers, the basis being the valuation made by the Commission.

It is stated that the office technical force of the Commission is now engaged in the computation and assembly of the large amount of data furnished by the field engineers. For this office work the Commission needs architects and engineers (civil, mechanical, electrical, structural, signal, telegraph and telephone). Senior architects and engineers are offered entrance salaries from $2,100 to $2,700 a year; junior engineers, $720 to $1,920; junior architects, $1,320 to $1,920. Rodmen and chainmen at $720 to $1,080 will also be appointed in the field and office forces. Employees are given a daily allowance for subsistence, as well as transportation expenses, when away on official business, and are also allowed the increase of $20 a month granted by Congress. The prospects for promotion are said to be good.

The Civil Service Commission will receive applications for these positions until further notice.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

INSTRUCTOR IN ELECTRICAL ENGINEERING at a university located in Central New York, duties beginning Sept. 15th. Must be an engineering school graduate. Opportunity offered to pursue post-graduate. Apply by letter stating age, education and experience, and enclose small photograph if available. Z-1727.

EQUIPMENT ENGINEERS. Men of intermediate type of technical training. Electrical or mechanical. Preferably electrical. These men will be trained in our work to tackle the problems of machine switching, telephony and equipment of new telephone offices with the latest developments in telephone practise. Location N. Y. City. Z-1730.

RESEARCH ENGINEER. Must have had advanced technical training and should have done responsible electrical research laboratory work. Should be familiar with the recent developments of vacuum tubes and high frequency telephone transmission. Should be capable of developing as an executive. Location N. Y. City. Z-1731.

ELECTRICAL ENGINEER with broad knowledge of power plant engineering and operation, and electric railway equipment, to make technical investigations and reports on industrial projects involving extensive use of electric powers, and on railway electrification problems, for the information of an analytical organization in New York City, interested in valuation of investment securities. Complete, detailed, and chronological statement of education, experience, and other qualifications and statement of salary expected, must accompany application. Z-1691.

ENGINEERS with technical and practical training in mechanical, structural, civil and electrical engineering wanted by progressive industrial concern which operates over a dozen plants with main office in Toledo, Ohio. We are organizing our own power, construction, and maintenance department and offer splendid opportunities to first class men who have had drafting experience, as duties include both office and field work. In reply state education, experience in full, salary desired, and when available. Location Ohio. Z-1668.

COMMERCIAL POWER ENGINEER experienced in analyzing and testing isolated power plants, a good general grounding in cost fundamentals, and some knowledge of power rates. Location New York State. Z-1671.

YOUNG MAN, about 25 years of age, with an appreciation for and not intolerant to engineering problems. Should know something about magnetic apparatus and be particularly strong on the subject of humidity, how to measure and control it. Location New York City. Z-1672.

CHIEF INDUSTRIAL ENGINEER, of broad experience wanted for major position on technical staff of an important analytical organization in New York City. Applicant must be familiar with various branches of engineering, and have ability to pass judgment on the scientific, technical and commercial soundness of industrial and other enterprises whose securities the analytical organization desires to consider in making investment recommendation to its clients. No attention will be paid to communications that do not contain complete, detailed chronological information relative to the education, experience, and other qualifications of the applicant. Men whose ability is worth less than $10,000 a year need not apply. Z-1661.

INSTRUCTOR to handle the correspondence course in Armature Winding. Practical experience in Armature Winding is an essential for the work. Teaching experience is somewhat desirable, but not at all essential. The theoretical part of the work does not enter; there is a slight amount needed. Man who knows the subject of Winding in several different ways, particularly in maintenance work, in general repair shop work and in shop manufacture. Location New York City. Z-1642.

FACTORY MANAGER—POLYPHASE MOTOR MANUFACTURE. Expansion of facilities and rearrangement of duties have left open position of Factory Manager. Satisfactory record of results accomplished must be submitted, including production and indicating a thorough familiarity with economical design and manufacture. This is an excellent opening for a man of the proper qualifications, and first communication should give complete information as to ability, salary expected, etc. Only those of proven ability will be considered. Location Michigan. Z-1620.

INSTRUCTOR to teach either or both electrical and mechanical engineering. Prefer young man with some practical experience or man who desires to come to the Pacific Coast for personal reasons. Location California. Z-1599.

ASSISTANT to engineer in charge of one of the best known electrical laboratories in the country is open to a technical engineer of several years laboratory experience. Principal duties will be to supervise the experimental and development work of the Laboratory. This work is chiefly on electrical measuring devices. Salary commensurate with experience and ability. Location New England. Z-1540.

MANAGER OF SHIPPING AND RECEIVING, to take charge of operations, involving large tonnage in connection with railroad, motor truck and marine shipments in a plant covering extensive acreage. Must be thoroughly experienced and able to take entire charge of organizing planning and carrying out the work efficiently. Plant located one hours ride from New York City. Z-1531.

SUPERINTENDENT OF MINING property in Chile. Technical graduate, preferably in Electrical or Mechanical. Executive and operating experience in electric railroading, steam turbine power plant, and open pit mining desirable. Only experienced men wanted. Knowledge of Spanish desirable, but not necessary. Good opportunity for right man. Give age, married or single. Education, technical training, technical and executive experience, salary expected, references and when available. Location Chile. Z-1355.

INSTRUCTOR IN ELECTRICAL ENGINEERING. Duties beginning September 1st, in New England Engineering College, mainly instruction in electrical engineering Laboratory.

Graduate of one or two years engineering experience desired. Z-1284.

ELECTRICAL AND MECHANICAL ENGINEER for 3000 h. p. hydro electric plant in Bolivia. Must be able to improve efficiency and take charge of plant. Z-1150.

TECHNICAL GRADUATE, with some teaching experience and some experience in the designing and testing of electrical machinery, to take charge of a dynamo laboratory, together with some classroom work, in a day and evening technical school in New York. Salary $2700. for nine months work. Write particulars, regarding age, education and experience. Z-1789.

MEN AVAILABLE

ELECTRICAL ENGINEER, technical graduate, 1916. Three years experience plant department of telephone and telegraph company. Some experience lighting and power layouts also teaching experience. Salary desired depends upon location and opportunity. E-2255.

ELECTRICAL ENGINEER, 8 years practical experience. Telephoning, Power House and Sub Station installation. Inspection. Testing. Age 28, Married. Available September 1st, 1920. E-2256.

ELECTRICAL AND MECHANICAL ENGINEER. Hold second assistant unlimited marine license, but prefer stationary work. Two years technical training. Seven year practical stationary and marine steam and electrical, 1 year office work with well known manufacturer of electrical equipment. Prefer permanent location New York City. E-2257.

ELECTRICAL ENGINEER. 29; married. Technical education; 4 years generating station and substation operation. Past 3 years in engineering offices on the design of stations, transmission, lighting, and industrial motorizing. Available August 1. Salary $2400 per year. E-2258.

MECHANICAL AND ELECTRICAL ENGINEER, age 36. Technical graduate. 13 years experience in design, construction and operation of hydraulic, steam and electrical installations. At present employed in large industrial plant as general superintendent. Experienced in organizing operating forces for new and unusual industries. Salary $6000. E-2259.

EXECUTIVE ASSISTANT to general manager or chief engineer of a manufacturing concern, holding company or public utility. Experience 2 years teaching; three years construction work; three years consulting engineering work for federal and state governments. Can assemble corps of engineers familiar with the Polish, Russian, German and French languages on reasonable notice. Member A. S. M. E. and A. I. E. E. Salary $4500-5000. E-2260.

GRADUATE ELECTRICAL ENGINEER, 6 months Westinghouse test, 2 years central station and sub-station design, 6 months factory illumination and motor control layout, 2 years U. S. Army Officer Motor Transport Corps, 5 years general automobile experience, desires commercial position. Available July 1st to go anywhere. Will consider any good proposition. E-2261.

ELECTRICAL MECHANICAL ENGINEER; practical and technical man open for engagement as superintendent of power, consulting, or developing engineer. Eleven years broad experience in management, maintenance, operation, construction, and installation of power plants and mines. Last three years spent in mining and oil field work. Minimum salary $3600. E-2262.

ENGINEER technically trained, 5 years railroad operating and construction experience. Also several years varied electrical work including 2 years General Electric Test. At present employed in engineering department of large electrical manufacturing concern but desire change to electrified Railroad field. Single, 35, Minimum salary $1800. E-2263.

ELECTRICAL ENGINEER, over 12 years experience in operation, design and construction. Desires position as Superintendent of operation or construction or responsible position in connection with design. Salary $3600 to start. E-2264.

ELECTRICAL ENGINEERING TEACHER, 12 years experience at institutions of recognized standing. Position leading to head of department preferred. Broad experience in commercial engineering work. Age 35, married. Minimum Salary $3500. E-2265.

PRACTICAL ELECTRICAL MAN—age 32, 10 years electrical experience desires position as Instructor of Electrical subjects. Thorough training in electrical work while in the army. Employed at present. Minimum salary $1600. References on request. E-2266.

ELECTRICAL ENGINEER. Want to locate with repair shop or dealer in used electrical machinery in vicinity of New York City. Experience covers armature winding, trouble work, buying and selling. Excellent references. E-2267.

ELECTRICAL ENGINEER, technical graduate, age 28, single. 2½ years Westinghouse test, 2 years United States Navy. 1 year construction work. Some research and production work, good organizer. Wish to locate with a power or industrial firm or with a manufacturer of machinery equipped with electric drive. E-2268.

UNIVERSITY GRADUATE in electrical engineering, single, age 29, eighteen months Westinghouse test, last two years naval officer. Some knowledge of Spanish, German, French and Russian. Desires position on construction work or operating. Will go to South America. E-2269.

TECHNICAL GRADUATE, desires sales or engineering work in or near Los Angeles, Cal., qualifications four years practical electrical work, four years sales experience, in addition to steam engineering training and experience in the navy. Can organize and manage sales agencies, age 31. E-2270.

ELECTRICAL ENGINEER. Technical graduate; age twenty four, single. Two and a half years experience in testing department of Westinghouse Elec. and Mfg. Co. Thoroughly familiar with all steam power plant apparatus, layout and construction. Desires position with consulting engineering firm or firm anticipating extensions in power system. Location west or middle west. Minimum salary $2100. E-2271.

ELECTRICAL ENGINEER, 31, married, ten years broad and intensive experience in large power and industrial plants, covering switchboard design and construction, power plant layout and erecting, shop practise and testing. Past two years with large manufacturing company as Erecting and Repair Engineer. Desire change to position requiring tact, efficiency and thorough knowledge of all phases of electrical construction and operation. Minimum salary $3000. Available on reasonable notice to present employers. E-2272.

PRACTICAL ELECTRICAL ENGINEER, 28, married. Three years technical training, 7 years engineering experience in construction, maintenance, central station work, mine and mill electrification and operation. Salary depends on location. E-2273.

GRADUATE ELECTRICAL ENGINEER, married, 36, twelve years construction and operation various types power plant and mill electrical apparatus. Experienced in large sizes and complex controls. Eight years of above with one of largest electrical manufacturing companies. Desires to locate off the "road". Present salary $3400. E-2274.

SALES REPRESENTATIVE, experienced salesman, with New York office and established clientele in automobile, hardware, electrical trades, solicits an additional account for Metropolitan district on commission basis. E-2276.

ELECTRICAL ENGINEER. Technical graduate, G. E. test-man. Experience in Radio Telegraphy and Telephony. Practical experience in factory production. Industrial manufacturing or Hydroelectric position desired where progress is assured according to ability shown. Position in consulting engineering office would be considered. Location in New England preferred. E-2277.

ELECTRICAL ENGINEER, age 32, married, technical education, 10 years with large electrical manufacturing company, on test floors and as engineer in charge of design of all classes of switching equipments including layout for large power house and substation installations. Energetic and a good organizer. Desire position as executive or as consulting engineer. Available August 1st. Middle West preferred. Salary dependent upon location and opportunities for advancement. E-2278.

SALES ENGINEER, wishes position with a manufacturing company, to act as agent representative or sales manager, for the sale of electrical and mechanical apparatus, familiar with New England territory and foreign trade. Or position with an undustrial organization for the development of above trade conditions. E-2279.

TECHNICAL GRADUATE, experienced in sub-station and high tension transmission design, desire a position where ability and hard work can be capitalized. Age 25, married. Location unimportant. E-2280.

MANAGER ENGINEERING DEPT. of Large New York Export & Import house desires to make a change. A graduate Electrical Engineer having also studied law, 29 years of age, single, with eight years commercial and engineering experience in U. S., Canada and Europe. A successful organizer and executive. Salary $6000. E-2281.

CONSTRUCTING AND OPERATING ENGINEER, executive ability, excellent personality, energetic, aggressive, M. I. T. 1915. Experience with Electric Light and Power Co. Assistant Electrical Engineer, Central Station design and develop-

ment of Operating statistics. At present with firm of Construction Engineers as Assistant Local Electrical Engineer, Design office, 200,000 K. W. Central Station. Responsible for purchasing all electrical material. Salary has increased 93% in ten months. Desire permanent location. Available 30 day notice. Salary $4000. E-2282.

TESTING ENGINEER, with three years electrical laboratory and eleven years public utility and central station experience. Am expert on all branches of electrical instrument and meter repair work. Location preferred New York City or vicinity. Salary $2400. E-2283.

GRADUATE ELECTRICAL ENGINEER, age 26, single, has had experience in telephone work, both automatic and manual; general plant maintenance, and in the design and layout of power houses and substations. Desires something permanent in any locality. E-2284.

ENGINEER, with eleven years practical experience in the Construction and Maintenance of High & Low Tension Transmission and Distribution Systems, Power Generation, Oil, Gas and Steam Engines; a competent executive; at present employed as general Superintendent of Light and Power over eleven towns and two plants. E-2285.

GRADUATE ELECTRIC AND MECHANICAL ENGINEER. Age 30. B. S. and E. E. degree with 10 years experience in the design of sub-station and power plants, also construction, industrial and commercial for light, heat and power. Employed at present with a public service corporation. Salary $2500 to start. Available at once. Location New York vicinity. E-2286.

INSTRUCTOR IN ELECTRICAL ENGINEERING, Electrical Engineer, age 26, degree B. S. 1917, employed in design and supervision of construction of electrical railway equipment, desires teaching position (engineering subjects) in technical school or college. Minimum salary $2200. Location in or near New York. E-2287.

ELECTRICAL ENGINEERING EXECUTIVE, thoroughly versed in modern efficiency methods of factory production, planning, scheduling and costs. Has had nine years experience in the design and manufacture of electrical cables. Good correspondent with knowledge of French and German. Seeks position with future. Minimum salary $4500. per annum. E-2288.

ELECTRICAL ENGINEER for large industrial plant desires immediate change to similar work. Graduate 1909, 33 years married, eleven years experience, covering apprentice, sales, testing, estimating, layout, maintenance and construction work. Salary $3600. E-2289.

ELECTRICAL ENGINEER, five years technical training, five years substation and steam turbo plant operation, five years assistant electrical engineer street lighting maintenance and construction, one year foreman power and lighting installations. Would consider export firm or local offering responsible position and broader opportunities. Salary commensurate with duties and location. E-2290.

GRADUATE ELECTRICAL ENGINEER, age 40, married with eighteen years experience in Mechanical and Electrical Engineering desires a position as Factory Manager, Superintendent, or Production Engineer, in a factory manufacturing electric motors, or other electrical apparatus. Minimum salary $4000. E-2291.

EXPERIENCED ELECTRICAL AND CIVIL ENGINEER with B. S. and M. S. Degrees from large universities, desires professorship of Engineering or headship of department of physics or in the manufacture and sale of scientific and engineering equipment. Has had experience as professor of Physics, electricity, and engineering branches. Also has served as assistant city engineer, highway engineer, and consulting electrical engineer, and one year as factory manager. Salary $6000. Location immaterial. Available short notice. E-2292.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—W. Ammen, 133 Franklin Ave., Mt. Vernon, N. Y.
2.—Edwin G. Helm, Construction Dept., Potomac Ry. & Pr. Co. Martinsburg, West Va.
3.—Carl Irving, 1253 West 51st Place, Los Angeles, Cal.
4.—Cyril H. Light, Office of Inspector of Engg. Material, U. S. N., 938 Edison Bldg., Chicago, Ill.

PERSONAL

CHARLES O. RAUSCHKOLB has been put in charge of a new sales office and service station of the Wagner Electric Manufacturing Company at No. 2007 South Ervay Street, Dallas, Texas.

J. R. WERTH has resigned as Major from the Construction Division of the Army and has opened an office at 6823 Thomas Street, Pittsburgh, for furnishing technical advisory reports to electrical and industrial corporations.

L. L. WILLARD sends announcement that the business heretofore carried on under the name of W. J. Rainey has been incorporated and will be conducted under the name of W. J. Rainey, Inc., at 52 Vanderbilt Avenue, New York City. Mr. Willard is a vice-president of the firm.

IRVING E. MOULTROP, Chairman of the Boston Section of the Institute, was on June 24 elected by the trustees of the United Engineering Society to fill the vacancy on that Board caused by the recent death of E. Gybbon Spilsbury, one of the trustees representing the American Society of Mechanical Engineers.

OBITUARY

LEWIS T. GLASER formerly electrical engineer with the Municipal Electric Light Plant of Cleveland, Ohio, died on June 8, 1920, after a lingering illness. Mr. Glaser started his electrical work in 1910 with the Wenatchee Valley Gas & Electric Company, Washington as a meter tester. In four years he became Assistant Superintendent. He then entered the employ of the Cleveland Municipal plant in charge of underground construction, wiring, switchboards, etc. Mr. Glaser was elected an Associate in the Institute in 1914.

FRANCIS W. THROOP, who was Hydraulic Engineer with the Empresa Electricas Asociados, Lima, Peru, was killed on March 24, 1920 at Chosica near Lima as the result of an accident. Mr. Throop, on a tour of inspection, was riding his horse along the banks of one of the streams feeding the hydroelectric plant. The bank, undermined by the freshets, gave way and rider and horse were lost. Mr. Throop was a graduate of Cornell in the class of 1892. On leaving college he accepted a position with the Bell Telephone Co., later entering the employ of the G. E. Co., the Pittsburgh Reduction Co. and others. In 1908 he became Power House Supt. for the Ft. Hamilton Cataract Power, Light & Traction Company at Hamilton, Ont. In 1918 he entered the employ of the Empresa Electricas Asociados. Mr. Throop was elected to the grade of Associate in the Institute in 1909.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (JULY 1-31 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

Direct-Current Motor and Generator Troubles—Operation and Repair.

By Theodore S. Gandy and Elmer C. Schacht. First edition. N. Y. & Lond., McGraw-Hill Book Co., Inc.; 1920. 274 pp., illus., tables, 8 x 6 in., cloth, $2.50.

The chief object of this book is to give simple, effective methods for finding and remedying troubles of direct-current motors and generators. In addition, the selection, operation, care and repair of direct-current machinery are analyzed from the operator's point of view. The theory underlying the design of these machines is omitted, as the book is intended for operators, not for designers.

Drainage Engineering.

By Daniel William Murphy. First edition. N. Y. & Lond., McGraw-Hill Book Co., Inc., 1920. 178 pp., illus., plates, tables, 9 x 6 in., cloth, $2.50.

This is a general treatise on the drainage of agricultural lands, which indicates the various questions to be considered in connection with a drainage project, and presents the principles involved in the design and construction of drainage works. The author was formerly a Drainage Engineer in the U. S. Reclamation Service.

Engineering for Land Drainage.

A Manual for the Reclamation of Lands Injured by Water. By Charles Gleason Elliott. Third edition, revised, N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1919. 363 pp., illus., maps, tables, 8 x 5 in., cloth, $2.50.

Contents: Development of Land Drainage.—The Drainage Engineer.—Engineering Technique.—Drainage and How Accomplished.—The Preliminary Survey.—Underdrains and their Location.—Flow in Underdrains. The Runoff from Underdrained Areas.—Size of Tile-drains.—Selection of Drain-tile.—Construction of Tile-drains.—Flow in Open Channels.—The Runoff from Large Areas.—Location and Construction of Open Ditches.—Problems in Openditch Work.—Drainage Districts.—Levee Drainage Systems.—Reclamation of Tidal Lands.—Drainage of Irrigated Lands.—Drainage of Peat and Muck Lands.—Control of Hill Waters.—Drainage of Home Surroundings.—Estimates and Accounts.—Records.—Tables.

This book is prepared to present the essential features of drainage engineering as practised in this country today and is adapted to the use of professional engineers and students. This edition has been revised and enlarged. The discussion of the hydraulics of flow has been rewritten and new tables for the discharge of tile drains are given. A diagram to facilitate the use of Kütter's formula in the design of ditches and canals has been added, as well as new material.

Die Helmholtzsche Wirbeltheorie Fur Ingenieure.

By G. Bauer. Munchen & Berlin. R. Oldenbourg, 1920. 146 pp., illus., diagrams, 10 x 7 in., paper, 14 marks.

The hydrodynamic problems met in such fields as airplane and ship building call for an acquaintance with the theory of vortex motion, but this theory, although it has for some time taken a considerable and useful place in electrical theory, is less well known by those engaged in other fields. It is the author's opinion that the chief cause of this ignorance is the lack of any work from which the engineer can obtain an understanding of the theory of vortices with a minimum of effort, a lack that the present monograph is intended to supply.

The method adopted is that of a commentary on Helmholtz's famous paper of 1858 on vortex motion. The paper is presented in full, with extensive illustrations and explanations. Helmholtz's two answers to Bertrand's papers on the motion of fluids are also included.

International Commerce and Reconstruction.

By Elisha M. Friedman. With a foreword by Joseph French Johnson. N. Y., E. P. Dutton & Co., copyright, 1920. 432 pp., tables, 8 x 5 in., $5.

Beneath the military campaigns of the war, a silent economic process has been changing the character of the commerce of the world. Profound changes have taken place, which this book attempts to trace in detail, and the principles of which it aims to discuss. It recites some of the facts essential to the formation of a new commercial and financial view and advocates a definite trade policy for the retention of our commercial gains from the war years.

Inventions. Their Development, Purchase and Sale.

By William E. Baff. N. Y., D. Van Nostrand Co., 1920. 230 pp., 8 x 5 in., cloth, $2.00.

The author of this work discusses the marketing of inventions. The subject is considered from the various points of view of the inventor, the capitalist or investor, and the manufacturer, and advice given to each as to the methods for making a correct judgment of the value of any invention.

Die Magnetische Induktion in Geschlossenen Spulen.

By Arthur Scherbius. Munchen & Berlin, R. Oldenbourg, 1919. 91 pp., illus., 10 x 7 in., paper, 7 marks.

This monograph treats of the possibilities, both theoretical and technical, of phase transformation by transformers and machines without commutators. The author discusses these possibilities with special reference to the limits within which technical applications may be possible and gives particular attention to the saturated transformer.

Manual for the Oil and Gas Industry under the Revenue Act of 1918.

By Ralph Arnold, J. L. Darnell and Others. N. Y., John Wiley & Sons, Inc.; Lond. Chapman & Hall, Ltd., 1920. 190 pp., charts, tables, 9 x 6 in., cloth, $2.50.

This manual was first issued in 1919 as a bulletin by the Oil and Gas Section of the Bureau of Internal Revenue. The demand having exceeded the supply, this private reprint, in which certain features have been brought up to date, is published.

The book is intended to assist the taxpayer of the oil and gas industry in preparing his Federal tax returns correctly and expeditiously. It is divided into three parts. Part one deals directly with the law and regulations, part two with depreciation, while part three describes methods of estimating underground reserves, especially by means of production curves, a collection of which are included.

RESISTANCE DES MATERIAUX ET ELASTICITE.

Cours Professé a l'Ecole des Ponts et Chaussées. By Gaston Pigeaud. Paris, Gauthier-Villars et Cie, 1920. 772 pp., diagrams, 8 x 6 in., paper, 64 francs.

This textbook represents the instruction given at L'Ecole des Ponts et Chaussees, and its arrangement, the author states, has been largely determined by the necessity of quickly preparing the students to apply the subject in the field of girders. At the beginning there is, therefore, no attempt to introduce the study by a preliminary exposition of the theory of elasticity, and throughout there is an avoidance of abstract principles.

After a brief review of the principles of mechanics and graphic statics, the theory of girders is explained. This is followed by a discussion of the various uses of the girder. The theory of elasticity is then introduced and occupies the concluding third of the book.

THE RUDDER MARINE DIRECTORY.

A Trade List of Shipbuilding and Marine Industries. N. Y., Rudder Publishing Co., 1920. 438 pp., 9 x 6 in., cloth, $5.00.

The title of this directory is sufficient indication of its contents, and suggests its possible usefulness to those interested in ship construction and operation. The present edition is considerably larger than the first, which appeared in 1919. The lists are conveniently classified and arranged to facilitate their use.

DIE SCHALTUNGSGRUNDLAGEN DER FERNSPRECHANLAGEN MIT WÄHLERBETRIEB.

By Fritz Lubberger. Munchen & Berlin, R. Oldenbourg, 1920. 168 pp., plates, 13 x 9 in., boards, 28 marks.

This book is intended to give engineers acquainted with manually operated telephone exchanges an introduction to automatic systems, which are frequently so confusing to the beginner. The author has made an extended examination of the systems of wiring used or proposed for this purpose and has selected the essentials of proper procedure from them.

Beginning with an easily understood automatic circuit, the book then proceeds to describe generally the principles of the various parts of the circuit, and follows this with explanations of the various systems that have been devised for the practical solution of the problems involved. The book includes bibliographical references, a list of German patents and many plates illustrating the arrangements described.

SERVICE AT COST PLANS.

An Identical Analysis of Statutes, Ordinances, Agreements and Commission Orders in Effect, or Proposed, together with a Discussion of the Essentials of Local Transportation Franchises. By Harlow C. Clark. N. Y., American Electric Railway Association, 1920. 315 pp., 9 x 6 in., cloth, $2.50.

The existing necessity for a readjustment of the rates for local transportation companies upon a basis that, while it protects the public from excessive charges, will attract the new capital necessary for the development of transportation facilities as extensions are demanded, has led to the introduction of various "service at cost" plans in a number of communities. This volume is intended to provide the public and the operators of local transportation facilities with a convenient summary of the principles and details of the various cost of service plans that have been adopted or proposed. It contains a statement of the principles that must underlie any legal expression of the right to conduct these utilities, if private capital is to be secured, an examination of the various statutes, ordinances and orders to ascertain the extent to which these principles have been applied, and identical analysis of the plans in service and proposed.

ROMANCE OF A GREAT FACTORY

Charles M. Ripley

The Gazette Press, Schnectady, N. Y. 1919.

"Romance of a Great Factory" presents the human interest side of present day industry as typified in a great factory, that of the General Electric Company at Schenectady, New York. While avowing that "with no effort to produce 'literature', these stories were hastily dictated while still under the spell of the spectacular and awe-inspiring scenes witnessed on various trips through our great factory employing nearly twenty-five thousand men", the author suceeds in putting before the reader a vivid and realistic picture of the factory life, with the shop worker and his interests in the foreground, and with a back ground of scientific and statistical information that adds to its value.

Following an introduction by Dr. Charles P. Steinmetz, the author plunges into factory life amid "The Great Industrial Orchestra", as the first chapter is entitled. He finds himself at 12:30 p. m. in building number 49 as the whistle blows to end the dinner period. "In less time than it takes to describe it, lathes, drill presses, cranes and hand tools all joined together singing their respective parts, and I was surrounded by a great industrial orchestra—the building reverberating to the indescribable song of American industry." He then shows the meaning of the song, which in building number 49 is "steel for our ships".

Each chapter is a story in itself, that may be read and enjoyed separately. The style is spontaneous, as the author dictated the work directly to his "Electrical Secretary", an "Ediphone" or Edison business phonograph; "Miss Edison", he explains, was always ready for anything, even taking a trip with him once on one of the ponderous cranes handling freight. Some of the chapters that are of special popular interest are Chapter XI, "The Girls' Part", in which the dexterity of the girls working in the factory is illustrated, and the safety and convenience of their working place are emphasized; and Chapter XII, "The Peace Celebration", which takes one back to November, 1918, to see the factory evacuated in less than an hour when the great steam whistle sounded.

Following the numbered chapters are "Fragments", among which items of interest are given Dr. Steinmetz's private system of shorthand, the average employe's years of service with the company, the number of fatal industrial accidents in the factory, showing that fishing is more dangerous than working in the factory, and the work of the Committee of One Thousand in selling Liberty Bonds, with a list of its members.

The book is profusely illustrated, and will prove of interest to members of factory organizations as well as to uninitiated outsiders.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Baltimore.—April 23, 1920, Engineers Club. Subject: "The Suspension Insulator for High-Voltage Power Transmission—Its Past and Future." Speaker Mr. F. H. Allner, of the Penna Water & Power Co. Attendance 28.

April 26, 1920, Johns Hopkins University. Joint meeting with Baltimore Section A. S. M. E. Subject: "The Super Power System." Speaker: Mr. W. S. Murray. Attendance 98.

May 14, 1920, Johns Hopkins University. Illustrated lecture on "The Safety Car." Speaker: Mr. C. H. Beck, of the Westinghouse Traction Brake Company. Attendance 49.

May 21, 1920, Engineers Club. Subject: "The Future of Hydroelectric Development." Speaker: Mr. W. C. Grover, U. S. Geological Survey.

Cleveland.—May 18, 1920, Rooms of Cleveland Engineering Society. Business meeting and election of officers as follows: Chairman, A. M. MacCutcheon; Secretary-Treasurer, G. M. Cameron; Chairman Papers Committee, Irving Van Horn; Directors, W. D. Smoot, E. S. Connell, H. S. Wallau, B. W. David (ex-officio). Attendance 140.

The business meeting was preceded by a dinner. Mr. P. M. Lincoln acting as master of ceremonies. Talks were given by

Messrs. Bush, MacCutcheon and others, followed by Professor V. Karapetoff, whose subject was "Some Present Day Problems in Electrical Research."

Detroit-Ann Arbor.—June 25, 1920, Detroit Board of Commerce. Annual Meeting and Banquet. Speakers: Messrs. E. S. Elliot, E. H. Martindale and D. V. Williams. Election of officers as follows: Chairman, C. E. Kittredge; Vice-Chairman, A. S. Albright; Secretary-Treasurer, C. E. Wise. Attendance 50.

Pittsburgh.—June 8, 1920, Chamber of Commerce Building. Election of officers as follows: Chairman, B. C. Dennison; Secretary-Treasurer, H. W. Smith; Executive Committee, Messrs. A. L. Broomall, G. Meedman, J. V. Peters, W. L, Shafer. Subject of meeting: "The Advantages of Interconnecting Industrial Power Plants." Authors: E. C. Stone, Duquesne Light Co., J. D. Thomas, West Penn Power Co.. F. C. Hamher, Westinghouse Elec. & Mfg. Co. Discussion was entered into by Messrs. Smith, Harvy, Kelly, Stoltz and Funck. Attendance 54.

Portland.—June 8, 1920, University Club. Annual dinner meeting. Election of officers as follows: Chairman, W. D. Scott; Secretary, W. C. Heston; Executive Committee, C. P. Osborne and O. L. LeFever. A talk on the subject of meterology was given by Mr. Edward Wells, Meterologist in charge of the Portland Station. Attendance 45.

St. Louis.—June 7, 1920, Engineers Club. Business meeting followed by presentation of paper on "The Broader Application of Engineering Methods" by Mr. B. H. Peck, General Manager of the Southern Illinois Light & Power Co. Attendance 63.

Spokane.—May 21, 1920, Davenport Hotel. Annual Meeting. Election of officers as follows: Chairman, R. S. Daniels; Secretary-Treasurer, L. J. Pospisil; Executive Committee, D. F. Henderson, B. M. Merrill and John B. Fisken. Subject of meeting: "Some Notes on Public Utilities Valuation." Speaker: Mr. Chas. A. Lund, Distribution Engineer of the City of Tacoma. Attendance 37.

PAST BRANCH MEETINGS

University of Cincinnati.—May 29, 1920, Chester Park Club House. Banquet. Reading of annual report and awarding of prizes for the best student papers. Professor Hoffmann acted as toastmaster. Toasts were given by Messrs. Wilson, Norton, Rodi, Osterbrock, Oster, Thomas, Nycum, Manson and Louis. Election of officers took place as follows: Chairman, R. S. Redmon; Vice-Chairman, G. C. Brown; Treasurer, Sec. 1, John Doran, Sec. 2, G. T. Addiston; Secretary, Professor C. B. Hoffmann. Attendance 67.

School of Engineering of Milwaukee.—June 18, 1920. Annual report was read, and election of officers as follows: Chairman, F. A. Kartak; Vice-Chairman, G. D. Rick; Secretary, L. F. Greve; Treasurer, C. E. Buchan. Attendance 50.

University of Notre Dame.—May 24, 1920, Engineering Building. Subjects: "Faraday and Maxwell, Their Part in the Development of the Science of Electricity" by D. Fitzgerald; "A Hydroelectric Power Plant to Supply Energy to a Paper Mill" by O. Ruzek. Attendance 23.

June 9, 1920. The Oliver Hotel. Annual Banquet. Addresses were given as follows: "The Development of the Department of Electrical Engineering at Notre Dame" by Rev. James Burns; "The Electrical Science and the Students of Engineering" by Rev. Thomas Irving; "A Survey of the Work of the A. I. E. E. Branch at Notre Dame" by Professor Caparo; "What is expected of Young Engineers" by Professor Benitz. Attendance 30.

Oregon State Agricultural College.—June 3, 1920. Election of officers as follows: Chairman, Roy C. Avrit; Vice-Chairman, Samuel Doukas; Secretary-Treasurer, Walter D. Olson. Attendance 14.

Stanford University.—May 3, 1920. Report of membership committee and other business. Attendance 17.

June 8, 1920. Illustrated lecture on "Super-sound" by Professor H. J. Ryan. Attendance 37.

University of Washington.—June 1, 1920, Forestry Hall. Subject: "The Long Lake Plant of the Washington Water Power Company and the Proposed Skagit River Development by the City of Seattle." Speaker: C. F. Uhden, City Engineer's Office. Attendance 35.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED JUNE 30, 1920

Addis, Judd, Clerk, Westinghouse Elec. & Mfg. Co., 1400 Alaska Bldg., Seattle, Wash.

Alender, Walter A., Traveling Electrical Inspector, Swift & Co., Union Stock Yards; res., 5525 S. Paulina St., Chicago, Ill.

Almquist, Paul B., Partnership, Western Tool Mfg. Co.; res., 822 So. Wabash Ave., Chicago, Ill.

Anderson, Burt T., Asst. Signal Engineer. Delaware, Lackawanna & Western Railroad Company, 312 Adams Express Bldg., Hoboken; res., 28 Salter Place, Maplewood, N. J.

Anderson, John F., Dispatcher, Hydro-Electric Power Commission of Ontario, Belleville, Ont.

Anderson, Russell E., Engineering Draftsman, H. M. Byllesby & Co., 208 S. La Salle St., Chicago, Ill.

Andresen, Hilmar, Bridge Designing Engineer, City of Chicago, 2001 City Hall Bldg.; res., 5024 N. Sawyer Ave., Chicago, Ill.

Andrews, Clyde B., Radio Electrician, Pearl Harbor Navy Yard, Pearl Harbor, Oahu; res., 1424 Victoria St., Honolulu, T. H.

Anglemyer, Wilbur J., Research Engineer, Kellogg Switchboard & Supply Co., Adams & Aberdeen Sts., Chicago, Ill.

Anson, Stuart M., Sales Engineer, Westinghouse Elec. & Mfg. Co., 1012 Park Bldg., Worcester, Mass.

Arenberg, Albert L., Illuminating Engineer, Central Electric Co., 316 S. Wells St., Chicago, Ill.

Argabrite, Harry H., Stores Manager, Western Electric Co. Inc., 1425 Curtis St., Denver, Colo.

Arnold, Samuel, 3rd, Electrical Engineer, American Bridge Co., Ambridge; res., 158 Dixon Ave., Ben Avon, Pittsburgh, Pa.

Bailey, Walter L., Asst. Electrical Engineer, Morgan & Wright; res., 449 Lenox Ave., Detroit, Mich.

Bair, D. Arthur, Asst. Chief Draftsman, Distribution Division, Commonwealth Edison Co., Chicago; res., Drexel Ave., La Grange, Ill.

Barmack, Boris J., Engineer, Commonwealth Edison Co., 72 W. Adams St.; res., 1124 S. Richmond St., Chicago, Ill.

Bason, George F., Instructor, Electrical Engineering Dept., Sibley College, Cornell University; res., 1007 E. State St., Ithaca, N. Y.

Bateman, Sidney J., Load Dispatcher, Essex Power Station, Public Service Electric Co.; res., 830 Mt. Prospect Ave., Newark, N. J.

Bates, Albert Wood, Manager, Western Electric Co., Inc., New Haven, Conn.

Batsel, Max C., Radio Engineer, Signal Corps, U. S. A., Camp Alfred Vail, N. J.

Battern, Algy Ross, Local Manager, Iowa Light, Heat & Power Company, Carroll, Iowa.

Bayer, Edward F., Jr., Inspector, Electrical Engineering Dept., Westchester Lighting Co.; res., 417 S. 4th Ave., Mt. Vernon, N. Y.

BEDFORD, LYNN N., Commercial Engineer, General Electric Co., 53 W. Jackson Blvd., Chicago, Ill.

BENDER, JOSEPH G., Patent Drafting Dept., Western Electric Co., 463 West St., New York, N. Y.

BERRY, THOMAS D., Supt., Engenia System, Hydro-Electric Power Comm. of Ontario, Toronto; res., Markdale, Ont.

BLISS, WILLIAM W., Transmission Engineer, The Pacific Tel. & Tel. Co., San Francisco; res., 6443 Hillegass Ave., Oakland, Cal.

BLYE, PAUL W., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

BOUSKA, JAMES W., Foreman, Repairs & Electrical Equipment, Commonwealth Edison Co.; res., 2255 So. Springfield Ave., Chicago, Ill.

BOWDEN, WILLIAM C., Electrical Contractor, 2 Repper Ave., Middle Village, L. I., N. Y.

BOWMAN, HERMAN N., Engineer, Western Electric Co., 463 West St., New York, N. Y.

BRADLEY, DANIEL L., Electrical Contractor, 11 W. Main St.; res., 1449 Willow Street, Norristown, Pa.

BRADSHAW, GEORGE H., Foreman, Switchboard Dept., Hydro-Electric Power Commission, 42 Culp St., Niagara Falls, Ont., Can.

BRITTON, EMMET W., Associate Editor, *Journal of Electricity*, 531 Rialto Bldg., San Francisco, Cal.

BROCKMAN, FRANCIS C., Radio Engineer, General Electric Co.; res., 217 Walnut St., Roselle Park, N. J.

BROKMANN, JOHN, Supervisor, Repairs, Electrical Equipment, Commonwealth Edison Co.; res., 1519 Hollywood Ave., Chicago, Ill.

BROWN, HARRY C., Electrical Draughtsman, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

BROWN, IRWIN E., Superintendent of Repairs, The Lehigh Valley Light & Power Co., Northampton; res., 1421½ Liberty St., Allentown, Pa.

BRUECKNER, JULIUS R., Works Manager, Gibb Instrument Co., 348 Palmer St. East, Detroit, Mich.

BUCK, KENDALL, Operating, White River Hydro-Electric Station, Puget Sound Power & Light Co., Dieringer, Wash.

BUFORD, PASCHAL, Agent, Western Electric Co.; Travis, Hayes, Williamson & Caldwell Co's., 208 W. 7th St., Austin, Texas.

BUNKER, EDMUND C., Chief Electrician, Power House, Charleston Consolidated Railway & Light Co.; res., 11 Radcliffe Place, Charleston, S. C.

BURGER, EDWARD J., Supt. of Distribution, Lorain County Electric Company, Lorain, Ohio.

BURNHAM, DAVID W., Electrical Draughtsman, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

BUTLER, ABNER I., Construction Foreman, General Electric Co.; res., 152 E. Superior St., Chicago, Ill.

BUZZELL, HAROLD W., Testing Dept., Commonwealth Edison Co., 28 No. Market St.; res., 6136 Ellis Ave., Chicago, Ill.

CAMERON, JAMES R., Salesman, Westinghouse Elec. & Mfg. Co., Law & Commerce Bldg., Bluefield, W. Va.

CAMP, CLIFFORD R., Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

CAMPBELL, LOUIS O., Construction Superintendent, General Electric Co., Monadnock Bldg., Chicago, Ill.

CARNAHAN, GROVE C., Foreman, W. A. Jackson Co., 760 Old Colony Bldg.; res., 6451 Greenwood Ave., Chicago, Ill.

*CATLETT, JAMES T., 4015 Meridian Ave., Seattle, Wash.

CERECEDO, JAVIER H., General Manager & Engineer, The Union Commercial Corp., and Cerecedo & Co., San Juan, P. R.

CHALLIES, JOHN B., Director of Water Power, Department of Interior, Ottawa, Canada.

CHAPEL, HARRIE D., Instructor, Milwaukee School of Engineering; res., 163 Mason St., Milwaukee, Wis.

CHAPPLE, EDWARD A., Electrical Mechanic, Toronto Hydro-Electric System; res., 89 Wroxeter Ave., Toronto, Ont.

CHARTERS, DALTON E., Electrical Engineer, Windsor Hydro-Electrical System, 31 Chatham St., Windsor, Ont., Can.

CHISHOLM, WILLIAM J., New York Edison Co., 327 Rider Ave., New York, N. Y.

CHRISTIANSEN, KAY AXEL, Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh; res., 512 Rebecca Ave., Wilkinsburg, Pa.

CLAUSSEN, WELLS H., Pole Lead Inspector, Dept. of Public Utilities, 507 County-City Bldg., Seattle, Wash.

CLEAVER, CHARLES H., Engineer in charge of Meter Dept., North Pacific Public Service Co., Bremerton; res., Manette, Wash.

CLOGER, EATON J., Asst. Instructor of Electrical Engineering, Mass. Institute of Technology, Cambridge; res., 8 Nottingham St., Dorchester, Mass.

CLOKE, PHILIP R., Instructor, Electrical Engineering Dept., Pennsylvania State College, State College, Pa.

COFFEY, FRANK J., Chief Electrician, Giant Powder Co., Giant, Cal.

CONWELL, RAY O., Operating Dept., Alabama Power Co., 935 Brown-Marx Bldg., Birmingham, Ala.

COOK, RALPH J., Testing Engineer, Van Dorn Electric Tool Co., 2978 Woodhill Road, Cleveland, Ohio.

COTTER, WILLIAM F., Engineer, Western Electric Co., 463 West St., New York, N. Y.; res., 68 Oakland Ave., Jersey City, N. J.

COULON, WILLARD S., Electrical Instructor, Vocational School, Camp Upton, N. Y.

COVER, LEO G., Supt. of Experimental Engineering, Laboratory, National Lamp Works of General Electric Co., Nela Park, Cleveland, Ohio.

COX, ALLEN H., Manager, A. H. Cox & Co., 307 First Ave., Seattle, Wash.

COX, ROBERT W. S., President, National Electrical Instrument Co., 21 Bromfield St., Boston, Mass.

CRESSINGHAM, RICHARD H., Asst. Div. Engineer, The Mountain States Tel. & Tel. Co., So. Division; res., 1216 N. Ange St., El Paso, Texas.

CRUMP, LINDELL L., Electrical Engineer, Union Electric Light & Power Co.; res. 4229 Botanical Ave., St. Louis, Mo.

CUMMINGS, GEORGE M., Telephone Exchange Maintainance, South Western Bell Tel. Co.; res., 4236 Cleveland Ave., St. Louis, Mo.

CURRY, ROY M., Inspector, Lincoln Electric Co.; res., East 8903 Birchdale Ave., Cleveland, Ohio.

CUTLER, RALPH D., Sales Manager, The Hartford Electric Light Co., Hartford, Conn.

DALY, WILLIAM F., Sales Engineer, Crocker-Wheeler Co., Old Colony Bldg., Chicago Ill.

DARE, CLIFFORD H., Electrical Instrument Maker, Brooklyn Navy Yard; res., 94 Clinton Ave., Brooklyn, N. Y.

DEAN, R. A., Electrical Inspector, Pullman Company, 701 Pullman Bldg.; res., 615 E. 112th St., Chicago, Ill.

DEBEECH, ALBERT V., Asst. Engineer, Motive Power Dept., Interborough Rapid Transit Co., 621 Broadway, New York, N. Y.

DE SILVIA, FRED E., Underground Electrical Construction & Maintenance, Puget Sound Traction, Light & Power Co., Electric Bldg., Seattle, Wash.

DEWAR, ALBERT, Central Office Equipment Engineer, The Pacific Tel. & Tel. Co.; res., 1409 Larkin St., San Francisco, Cal.

DIBBLEE, JOHN, Electrical Engineer, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

DINWIDDIE, James A., Salesman, Westinghouse Elec. & Mfg. Co., 1137 Ohio Bldg., Toledo, Ohio.

DIPPEL, HOWARD W., Inspection, Western Electric Co., Inc., 463 West St., New York; res., 532 Jamaica Ave., Astoria, L. I., N. Y.

DOBBERPUHL, RAY H., Sales Engineer, Cutler-Hammer Mfg. Co., 12th St. & St. Paul Ave., Milwaukee, Wis.

DOOLEY, DANIEL R., Engineer, Automatic Electric Co., Morgan & Van Buren Sts., Chicago, Ill.

DORAN, PATRICK E., Asst. Manager, Douglas Traction & Light Co.; res., 922 12th St., Douglas, Ariz.

DOYLE, EDWARD F., Production Supt., Cable & Insulating Mills, National Conduit & Cable Co., Hastings-on-Hudson, N. Y.

DREBING, C. L., Foreman Electrician, Pullman Co.; res., 8914 Exchange Ave., Chicago, Ill.

DUFFIN, CHARLES G., Engineer, The Pacific Tel. & Tel. Co., 507 Sheldon Bldg., San Francisco, Cal.

DURHAM, BARRY G., Chicago Manager, Albert & J. M. Anderson Mfg. Co., 150 South Dearborn St., Chicago., Ill.

EATON, CECIL L., Sales Engineer, A. H. Cox & Co.; res., 710 Terry Ave Seattle, Wash.

EATON, DEAN W., Superintendent, Sun Electric Co., Bartlesville, Okla.

ELLIS, GOULD, System Operator, Ohio Power Co., 217 Cleveland Ave., N. W., Canton, Ohio.

ERICKSON, EMIL, Commonwealth Edison Co.: res., 6443 S. Lincoln St., Chicago, Ill.

ERIKSON, EBEN W., Manager, St. Louis Office, Victor Electric Corp., 214 University Club Bldg., St. Louis, Mo.

ERLANGER, ARNOLD, Sales Engineer, Monitor Controller Company, 30 Church St., New York, N. Y.; res., Westfield, N. J.

EVANS, BENJAMIN D., Draftsman, Patent Department, Western Electric Co., 463 West St., New York, N. Y.; res., Garwood, N. J.

EVERSON, RUSSELL B., Chief Electrician, The Okonite Co., Canal St., Passaic; res., 86 Lakeview Ave., Clifton, N. J.

FALLIS, GORDON W., Operating, White River Hydro-Electric Station, Puget Sound, Power & Light Co., Dieringer, Wash.

FARALLA, RAOUL A., 1834 Coney Island Ave., Brooklyn, N. Y.

FARLEY, WILLIAM C., Supt., Kentucky Utilities Co., Harlan, Ky.

FARRINGTON, JOHN F., Radio Engineer, Western Electric Co., 463 West St., New York, N. Y.

FAST, JOHN E., Electrical Engineer, American Telephone & Telegraph Co., 311 W. Washington St., Chicago, Ill.

FAY, CHARLES A., Chief Electrician, The Prest-O-Lite Co., Inc.; res., 4206 Cornelius Ave., Indianapolis, Ind.

FERNALD, JOHN M., Salesman, Cutler-Hammer Mfg. Co., 77 Franklin St., Boston, Mass.

FINN, WALTER E., Sales Engineer, Cutler-Hammer Mfg. Co., 323 No. Michigan Ave., Chicago, Ill.

FLAMMER, HOWARD A., Draftsman, Western Electric Co., 463 West St., New York, N. Y.; res., 92 Richelieu Terrace, Newark, N. J.

FLINT, GLENN E., Electrician, Margaret Street Substation, Turners Falls Power & Electric Co.; res., 24 Montmorenci St., Springfield, Mass.

FLYNN, THOMAS F., Electric Inspector, Public Service Commission, Albany; res., 1863 9th Ave., Watervliet, N. Y.

FONTANA, CHRISTOPHER L., Long Lines Dept., American Tel. & Tel. Co., Boatmen's Bank Bldg., St. Louis, Mo.

FORREST, ELBERT E., Engineer, Gary Heat, Light & Water Co., 5th Ave. & Broadway, Gary, Ind.

FREEPARTNER, JOHN J., Telephone Engineering, City of Seattle Public Utilities, Seattle, Wash.

FRICK, GEORGE H., Chief Electrician, The Mohawk Rubber Co., River & Second St., Akron, Ohio.

FURTICK, GROVER C., Erecting Engineer, General Electric Co., Witherspoon Bldg., Philadelphia, Pa.

*GARVER, PAUL L., Electrical Engineer, Designing, Industrial & Railway Motor Engineering Dept., Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

GASKELL, JOSEPH F., Power Engineer, Philadelphia Electric Co., 1000 Chestnut St., Philadelphia; res., 204 Florence Ave., Jenkintown, Pa.

GASTONGUAY, EMILE, Chief Electrician, Alaska Gastineau Mining Co., Thana, Alaska.

GIBSON, EARL S., Engineer, Tel. Systems Engg. Branch, Western Electric Co. Inc., 463 West St., New York, N. Y.

GILDROY, JOHN L., Electrical Contractor, Gildroy Bros., 2151 So. Leavitt St., Chicago, Ill.

GILES, RAYMOND B., Draftsman, Great Western Power Co., 14 Sansome St., San Francisco, Cal.

*GIVEN, LOUIS E., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

GONZALEZ, JUAN I., 50 W. 96th St., New York, N. Y.

GORBAKOWSKY, ILIA, Consulting Engineer, Peoples Industrial Trading Corp., 140 Nassau St., New York, N. Y.; res., 42 W. 38th St., Bayonne, N. J.

GORHAM, EMMET B., Asst. Illuminating & Testing Engineer, Commonwealth Edison Co.; res., 2925 Congress St., Chicago, Ill.

GOSS, C. H., Electrician, Consumers Power Co., res., 116 Mc Bride St., Jackson, Mich.

GRAHAM, FRANK H., Telephone Engineer, Western Electric Co., 463 West St.; res. 546 W. 157th St., New York, N. Y.

GREENHILL, DOUGLAS C., Telephone Engineer, Northern Electric Co.; res., 4171 St. Catherine St., Westmount, Montreal, Canada.

GREGSON, MONTRUVILA E., Asst. General Foreman, Dist. Dept., The New York Edison Company, 171 West 107th Street, New York, N. Y.

GRIFFETH, GERALD G., Equipment Engineer's Office, The Pacific Tel. & Tel. Co., Sheldon Bldg., San Francisco, Cal.

*HADA, TSUNEZO, Head of Research Dept., Hitachi Engineering Works, Sukegawa, Ibaragiken, Japan.

HADDEN, WESTON, Asst. Electrical Engineer, Western Electric Co., Inc., 463 West St., New York; res., 1716 Albermarle Road, Brooklyn, N. Y.

HAIGHT, AARON L., Assistant Engineer, New York & Queens Electric Light & Power Co., Electric Bldg., Long Island City, N. Y.

HAM, J. E., Commercial Electrical Engineer, General Electric Co., 1026 Monadnock Bldg., Chicago, Ill.

HAMILTON, WALTER L., Electrical Testing Engineer, 11 Norwood Terrace, Holyoke, Mass.

*HAMMOND, FREMONT M., Operating Engineer, Radio Station, Marion, Mass.; res., 160 E. Main St., Patchogue, N. Y.

HANGAARD, FREDERICK B., Electric Light Dept., Town Hall, Sydney, res., 294 Edgewater Road, Newton, N. S. W., Aus.

HANNON, FRANK R., Electrical Supt., Ordnance Dept., U. S. Government, Raritan Arsenal, Metuchen, N. J.

HANSEN, GEORGE J. C., Asst. Supt., Repair Shops, Commonwealth Edison Co., 28 N. Market St., Chicago, Ill.

HARMAN, RICHARD A., Foreman, Repair Shop, Hughes-Peters Electric Co.; res., 1387 N. 4th St., Columbus, Ohio.

HARMS, RHINEHART W., Western Sales Manager, R. Thomas & Sons Co., 1055 Old Colony Bldg., Chicago, Ill.

HART, M. EMANUEL, Owner, Enterprise Electrical Co., 407 Baronne St., New Orleans, La.

HASHIMOTO, SEIJI, Naval Engineer, 1 Madison Ave., New York, N. Y.

HAWLEY, ALBERT B., Transformer Dept., General Electric Co.; res., 74 Edward Ave., Pittsfield, Mass.

HELMER, WALTER S., Shops & Equipment Dept., Chicago Elevated Railroads, 1341 Edison Bldg., 72 W. Adams St., Chicago, Ill.

HERZ, W. E. H., Representative of Compagnie Francaise, Thomson-Houston, Paris, France; General Electric Co., Lynn, Mass.

HETH, WILLIAM A., Electrical Designer, The Milwaukee Elec. Ry. & Light Co., Public Service Bldg., Milwaukee, Wis.

HEUSER, JOHN N., Salesman, Cutler-Hammer Mfg. Co., Peoples Gas Bldg., Chicago, Ill.

HILL, CURTISS L., Asst. Supt., Power & Equipment, Tacoma Railway & Power Co., Tacoma, Wash.

HILL, HERBERT R., Hydro-Electric Power Commission of Ontario, 190 University Ave.; res, 555 Euclid Ave., Toronto, Ont.

HINCHLIFF, EDWIN L., District Supt., Ironwood & Bessemer Railway & Light Co., Ironwood, Mich.

HIZAWA, GOTARO, Manager, Power & Mining Dept., Shibaura Engineering Works, Shiba, Tokyo, Japan.

HOCKADAY, OLIN S., Testing Dept., General Electric Co., 603 Interurban Bldg., Dallas, Texas.

HODGKINS, W. J., General Supt., Ashland Light, Power & Street Railway Co.; and Ironwood & Bessemer Railway & Light Co., Ashland, Wis.

HOFFMAN, R. A. Junior Engineer, The Denver Gas & Electric Light Co.; res., 475 Corona St., Denver, Colo.

HOLLAND, JOHN R., Erecting Engineer, General Electric Co.; res., 535 North Troy St., Chicago, Ill.

HOLMES, TYLER L., Manager, Western Electric Co., Inc., 1425 Curtis St., Denver, Colo.

HOOT, HAROLD T., Engineering Asst., New York Telephone Co., 15 Dey St., New York, N. Y.

HORINE, KARL, Testing Engineer, Commonwealth Edison Co., 28 N. Market St., Chicago; res., 1125 Oak Ave., Evanston, Ill.

HORTON, J. WARREN, Engineer, Western Electric Co., 463 West St., New York, N. Y.; res., 105 So. Grove St., E. Orange, N.J.

HORTON, WILLIAM F., Engineering Asst., Automatic Engineers Office, Western Union Telegraph Co., 195 Broadway, New York, N. Y.

HUNT, EDWARD C., Engineer, Valuation Dept., Pacific Gas & Electric Co., 445 Sutter St., San Francisco, Cal.

HYLAND, JOSEPH L., Electrician and Switchboard Operator, Turners Falls Power & Electric Co., 409 Union St., W. Springfield, Mass.

HYNDMAN, FRANKLIN L., Requisition Engineer, General Electric Co.; res., 14 S. Church St., Schenectady, N. Y.

ILER, STANLEY B., Asst. Engineer, Hydro-Electric Power Comm. of Ontario, 190 University Ave., Toronto, Ont.

IMBERY, ARTHUR, Leeds Electrical Construction Co. Ltd., Charmouth St., Leeds, Eng.

IMHOFF, ELDON A., Engineer, Chicago Elevated Railway, 72 W. Adams St.; res., 2441 N. Rockwell St., Chicago, Ill.

IRONSIDE, GEORGE A., Assistant Superintendent, Hydro-Electric Power Commission, Merchants Bank Bldg., Hamilton, Ont., Can.

ISHIDA, SHINICHIRO., Chief Electrical Engineer, 3rd Div., Kiso Electrical & Industrial Co., Nagoya, Japan.

ISHIMARU, EIKICHI, Electrical Designer, Shibaura Engineering Works., Tokio, Japan.

JACINTO, SANCHO R., Electrician, Malolos Electric Light & Ice Power Co., Malolos, Bulacan, P. I.

JACKSON, HARRY L., Chief Electrician, Three Forks Portland Cement Co., Hanover, Mont.

JANSSEN, HERMAN F., Sales Engineer, Allis-Chalmers Mfg. Co.; 807 Franklin Trust Co., Philadelphia, Pa.

JEWELL, LEONARD, Electrician, A. R. Williams, Front St.; res., 193 Glenholme Ave., Toronto, Ont., Can.

JERMAN, ED. C., Instructor X-Ray Tecnique, Victor Electric Corp., 236 S. Robey St., Chicago, Ill.; res., Topeka, Kansas.

JOHNSON, ARTHUR C. K., Sales Engineer, V. V. Fittings Co.; res., 1446 Balmoral Ave., Chicago, Ill.

JOHNSON, RAYMOND H., Designer & Engineer, Columbia Graphophone Co.; res., 78 Rowsley St., Bridgeport, Conn.

JOHNSTON, ROBERT M., Factory Manager, Jeffery-Dewitt Insulator Co., Kenova, W. Va.

JOHO, ERNEST C., Draftsman, Western Electric Co., Inc., 463 West St., New York, N. Y.

JONES, CLINTON, Commercial Engineer, General Electric Co., Pittsfield, Mass.

JONES, ERNEST, Jones & Hitchen, Louja del Comercio, Havana, Cuba.

JONES, PHILIP FRANK, Engineer, Development & Research Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

JONES, RAY V., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

JONES, ROBERT A., Electrical Engineer, Power & Mining Engineering Dept., General Electric Co., Schenectady, N. Y.

JORDAN, THOMAS, Plant Electrician, Utah Copper Company, Arthur, Utah.

JOYCE, WILLIAM B., Salesman, Electrical Engineering Equipment Co. of Chicago, 84 State St., Boston; res., Salem, Mass.

JULIUS, DIETRICH J., Chief Electrician, U. S. Navy, Navy Recruiting Station, Meridian, Miss.

KARCHER, E. KENNETH, Electrical Engineer, Utica Gas & Electric Co., Utica, N. Y.

KASAI, KWAN, Electrical Engineer, Electrotechnical Laboratory, Ministry of Communications, Tokyo, Japan.

KEEFE, THOMAS F., Supt., Transmission & Distribution, Ironwood & Bessemer Railway & Light Co., Ironwood, Mich.

KEENAN, GEORGE M., Supervisor of Operation, The Lehigh Valley Light & Power Co., Front St. Plant, Allentown, Pa.

KEESE, FOSTER D., Instructor, International Correspondence Schools; res., 1504 Capouse Ave., Scranton, Pa.

KELLY, JOHN J., Asst. to Works Supt., Canada Carbide Co. Ltd., Shawinigan Falls, Quebec, Can.

KIDDER, JAMES W., Supervisor, Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

KILGALLEN, JAMES D., Electrical Draftsman, Western Electric Co. Inc., 463 West St.; res., 4312 Kepler Ave., New York, N. Y.

KINER, GLENN, Engineer, Kellogg Switchboard & Supply Co., 1066 W. Adams St., Chicago, Ill.

KING, LOUIS M., Asst. Chief Electrician, Coke Works, American Steel & Wire Co., Cleveland, Ohio.

KINSMAN, FRED, Electrical Engineer, Ford Motor Co.; res., 813 Garland Ave., Detroit, Mich.

KINSMAN, RUSSELL C., Instructor, University of Alabama, Tuscaloosa, Ala.

*KIRKPATRICK, THOMAS P., Industrial Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

KISTLER, WILLIAM J., Chief Electrician, Hauto Plant, Lehigh Valley Light & Power Co., Hauto; res., Summit Hill, Penn.

KLEIN, HARRY R., Inspection Engineer, Lehigh Power Securities Corp., Hunsicker Bldg., Allentown, Pa.

KNAPP, CARL M., Electrical Engineer, Crown Oil & Refining Co., Pasadena; res., 4803 Fannin St., Houston, Texas.

KNAPP, FRANK E., Foreman, Electrical Maintenance, Morgan & Wright (U. S. Rubber Co.); res., 1475 Vinewood Ave., Detroit, Mich.

KNOX, CARLOS C., Electrical Engineer, Cleveland Electric Illuminating Co., Illuminating Bldg., Cleveland, Ohio.

*KNUTZ, JAY H., Assistant Inspector, Public Service Co. of Northern Illinois, 10 Illinois St., Chicago Heights, Ill.

KOCH, MARSHALL M., Field Engineer, Henry L. Doherty, 60 Wall St., New York, N. Y.

KOLLATH, FRANCIS C., Electrical Inspector, The Pullman Co.; res., 4821 W. Eddy St., Chicago, Ill.

KOMM, PAUL M., Manufacturing Research, Western Electric Co.; res., 1726 Wallen Ave., Chicago, Ill.

KOPPRASCH, ALEXANDER, Supervising Engineer, Electrical Manufacturer's Equipment Co.; res., 3633 N. Ashland Ave., Chicago, Ill.

KUHN, ARTHUR H., Engineer, H. M. Byllesby & Co., 208 So. La Salle St., Chicago, Ill.

KUSHLAN, MAX, Senior Bridge Designing Engineer, City of Chicago, City Hall Square Bldg., Chicago, Ill.

KUTTEL, FRANK P., Student Engineer, Testing Dept., General Electric Co., Schenectady, N. Y.

KVAAL, ANDREW B. S., Engineering Dept., Western Electric Co., Inc., 463 West St., New York, N. Y.

LA BARR, OLIVER EARL, District Agent, Puget Sound Power & Light Co., Bothell, Wash.

LANDRY, KENNETH W., Asst. Supt., Worcester Electric Light Co.; res., 295 Park Ave., Worcester, Mass.

LANSFORD, WILLIS R., Secretary, Hohn Collins Co., 427 C St., N. W.; res., 3607 13th St., N. W., Washington, D. C.

LAWLER, ELLIOTT R., Asst. Engineer, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.

LAWSON, WILLIAM G., Asst. Supt. of Lines, Hydro-Electric Power Commission of Ontario, Merchants Bank Bldg., Hamilton, Ont.

LAZARA, MICHAEL P., Electrician, Bliss Electrical School, Tacoma Park, Washington, D. C.

LEE, ROBERT E., General Electric Co., 411-413 National Realty Bldg., Tacoma, Wash.

LEONARD, Leon H., Electrical Engineer, Cutler-Hammer Mfg. Co., 12th & St. Paul Sts., Milwaukee, Wis.

LEWIS, HOWARD A., Advertising Director, Electrical Trio, McGraw Publishing Co., 10th Ave. & 36th St., New York, N. Y.

LIEBER, CHARLES A., Electrical Engineer, Wagner Electric & Mfg. Co., 6400 Plymouth Ave.; res., 3868 Russell Ave., St. Louis, Mo.

LIVERMORE, L. S., Load Dispatcher, Puget Sound Traction, Light & Power Co.; res., 1142 19th Ave. North, Seattle, Wash.

LOBECK, ADOLF J., Engineer, 285 Warburton Ave., Yonkers, N. Y.

LOW, DAVID, Lockwood, Green & Co., 245 State St., Boston, Mass.

LOWE, J. CORNELIUS, President, Laco Lamps, Ltd., 23 Doud St., Montreal, Quebec, Can.

MACLEAN, GEORGE L., Electrical Engineer, Canadian Connecticut Cotton Mills, Ltd., Sherbrooke, Que.

MAC MURPHY, FRANKLIN, Student, Columbia University; res., 301 West 108th Street, New York, N. Y.

MANN, EARL K., Instrument Repairman, Hickock Instrument Co.; res., 874 E. 105th St., Cleveland, Ohio.

MARTIN, MERRITT K., Substation Operator, Puget Sound Traction, Light & Power Co., Bothell, Wash.

MARTIN, NEILL H., Electrical Draftsman, Sargent & Lundy, Edison Bldg., Chicago, Ill.

MASON, FREDERICK G., Foreman, Meter Dept., Ironwood & Bessemer Railway & Light Co., Ironwood, Mich.

MASON, JORDAN A., Engineering Dept., General Electric Co., Monadnock Bldg.; res., 152 E. Superior St., Chicago, Ill.

MATHES, CARL F., Supt., Electric Meter Dept., Carolina Power & Light Co., Raleigh, N. C.

MATHIS, ANDREW W.. Chief Load Dispatcher, Puget Sound Traction, Light & Power Co., 600 Electric Bldg., Seattle, Wash.

MATHIS, GOULD G., Load Dispatcher, Puget Sound Traction, Light & Power Co.; res., 2624, 1st Ave. North, Seattle, Wash.

MAY, JOHN T., Equipment Engineer, Eng. Dept., Western Electric Co., Hawthorne Works, Chicago, Ill.

MAYER, JOHN H., Asst. Division Engineer, Postal Telegraph & Cable Co., 253 Broadway, New York, N. Y.

McCONNACHIE, WILLIAM, Electrical Designer, A. C. Engineering Dept., British Thomson-Houston Co. Ltd. Rugby, Eng.

McCULLOUGH, PHILLIP M., Outside Plant Construction Engineer, Nebraska Telephone Co., Omaha, Neb.

McDONALD, JAMES W., Jr., Draughtsman, Stone & Webster Eng. Corp., 147 Milk St.. Boston, Mass.

Mc FARLAND, WILLIAM E., Power Distribution Engineer, Cleveland Electric Illuminating Co., 308 Illuminating Bldg., Cleveland, Ohio.

McINTYRE, JOHN A., Telephone Engineer, Western Electric Co., 463 West St., New York, N. Y.

McKAY, FRED M, Engineering Dept., Athens Electric Co., 29 South Court St., Athens, Ohio.

McKENZIE, ROBERT M., Municipal Dept., Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.

Mc KINLEY, RICHARD T., Electrical Inspector, Pullman Co., 701 Pullman Bldg., Chicago, Ill.

McNETT, RICHARD F., Supervisor of Power, The Robbins & Myers Co.; res., 139 E. Cassilly St., Springfield, Ohio.

McPHERSON, HARRY L., Valuation Accounting, Engineering Department, Puget Sound Traction, Light & Power Company, 602 Electric Bldg., Seattle, Wash.

MEAGHER, JAMES P., Chief Electrician, H. McN. Dockyard; res., 146 Argyle St., Halifax, N. S.

*MEEHAN, THOMAS P., Asst. Inspector, Public Service Company of Northern Illinois; res., 73 Hickory St., Chicago Heights, Ill.

MEISTER, GEORGE J., Engineering Department, Crocker-Wheeler Co., Ampere; res., 78 South 13th St., Newark, N. J.

*MEJIA, JULIO E., Student, Rensselaer Polytechnic Institute; res., 1809, 7th Ave., Troy, N. Y.

MERRITT, HAROLD W., Designing Engineer, The Cutler-Hammer Mfg. Co., Milwaukee, Wis.

MEYER, CLAUDE PERRY, Sales Engineer, Century Electric Co., 1827 Pine St., St. Louis, Mo.

MIDDLETON, ELLIOTT W., Electrical Engineer, Front Street Station, The Lehigh Valley Light & Power Co., Allentown, Pa.

MILLIKIN, KEITH C., Asst. Manager, Midland Hydro-Commission, Bay St., Midland, Ont.

MITCHELL, SAM E., Sales Agent, General Electric Co., 609 Colman Bldg., Seattle, Wash.

MIX, MARTIN I., Asst. Supt. of Pressures, Peoples Gas Light & Coke Co., 122 So. Michigan Ave., Chicago, Ill.

MOALE, EDWARD S., Electrician, Motive Power Dept., Interborough Rapid Transit Co., 600 W. 59th St., New York, N.Y

MONG, CLIFFORD E., Supervising Toll Foreman, Pacific Tel. & Tel. Co., 324 Sheldon Bldg., San Francisco, Cal.

MORE, THOMAS R., Operator, North Coast Power Co., McMinnville, Oregon.

MORGAN, JOSEPH McDOWELL, Electrician, Potomac Electric Power Co.; res., 621 Upshur St. N. W.. Washington, D. C.

MOSS, MALCOLM W., Assistant in Physics, Massachusetts Institute of Technology, Cambridge; res., 44 Fairfield St., Boston, Mass.

MUENCH, FRED C., Draftsman, Bureau of Standards; res., 2945 Tilden St., Washington, D. C.

MULFORD, ALLEN, Electrical Engineer, International General Electric Co., Schenectady, N. Y.

MURDOCK, ALFRED W., Electrical Engineer, Hydro-Electric Power Comm. of Ontario; res., 177 College St., Toronto, Ont., Can.

MURIAN, STEPHAN B., Supervisor of Design, Sessions Engineering Co., 22 W. Monroe St., Chicago, Ill.

MURPHY, J. RAYMOND, Electrical Engineer, Electrical Dept., Pacific Commercial Co., Manila, P. I.

NASH, DE LLOYD D., Electrical Engineer, Standard Oil Co. of N. J.; res., 424 Cherry St., Elizabeth, N. J.

NEIL, HARRY A., Chief Operator, Niagara, Lockport, & Ontario Power Company; res., 76 Phelps St., Lyons, N. Y.

NELSON, OSCAR L., Dist. Equipment Supervisor, Western Union Tel. Co.; res., 2135 Sixth St. North, Minneapolis, Minn.

NICHOLSON, ALBERT C., General Electrical Foreman, Illinois Steel Company (South Works); res., 7229 Merrill Ave., Chicago, Ill.

NIELSEN, ROBERT N., Draftsman, Lockwood, Greene & Co.; res., 1719 N. Keeler Ave., Chicago, Ill.

NIXON, NORMAN J., Draftsman, Canadian Westinghouse Co.; res., 254 Prospect St., Hamilton, Ont.

NORTH, S. H., Service Engineer, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

NORTON, CHESTER A., Branch Manager, Westinghouse Lamp Co., 1409 Alaska Bldg., Seattle, Wash.

NORTON, EDGAR A., Service Dept., Canadian Westinghouse Co., Hamilton, Ont., Canada.

*NOTT, GORDON E., Asst., Testing Dept., Hydro-Electric Power Commission Laboratories, 8 Strachan Ave., Toronto, Ont., Can.

OKUNO, SUTEZO, Graduate Student, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

OLSON, WILLIAM J., Operator, Light Department, City of Seattle; res., 508 30th Ave., Seattle, Wash.

OSBURN, MASON B., Asst. Supt., Pullman Car Works, Pullman, Ill.

OTT, VOYLE D., Engineering Research Laboratory, Webster Electric Co., Racine, Wis.

PALUEFF, KONSTANTIN K., Transformer Engineering Dept., General Electric Co.; res., 15 Myrtle St., Pittsfield, Mass.

PARKER, HARRY C., Electrical Engineer, Canadian General Electric Co., 212 King Street West, Toronto, Ont.

PATTERSON, ROBERT D., Commercial Engineer, 50 Church St., New York; res., 1259 78th St., Brooklyn, N. Y.

PEARCE, EDGAR B., Asst. Division Engineer, Eastern Division, Postal Telegraph Cable Co., 253 Broadway, New York, N. Y.

*PEARSON, OSCAR A., Electrical Engineer, Thordarson Electric Mfg. Co., 501 Jefferson St., Chicago; res., Crystal Lake, Ill.

PEDERSON, THORVALD, Inspecting Engineer, Cutler-Hammer Mfg. Co., 1238 Guardian Bldg., Cleveland, Ohio.

PERKINS, CYRUS A., Draughtsman, Hydro-Electric Power Commission; res., 122 University Ave., Toronto, Ont.

PERKINS, GUY S., Salesman, Root-Neal Co.; res.. 2375 Main St., Buffalo, N. Y.

PERKINS, HAMMOND M., Electrical Tester, General Electric Co., Lynn; res., 367 Central St., Auburndale, Mass.

PETERSON, HAROLD D., Equipment Engineer. N. Y. Telephone Co., Long Island Div.; res., 1946 E. 15th St., Brooklyn, N. Y.

PETTENGILL, HARRY C., Electrical Engineer & Estimator, William A. Corrao Electric Co., 507 Manhattan Bldg., Chicago, Ill.

PICKERING, ALBERT E., Manager, The Great Lakes Power Co., Ltd., Sault Ste Marie, Ont., Canada.

PLATT, BRUCE C., Asst. Elec. Engr., Hydro-Electric Power Comm. of Ontario, 190 University Ave., Toronto, Ont., Canada.

PLOWMANN, CARROL S., Asst. Chief Operating Engineer, Singer Manufacturing Co., Elizabethport; res., 30½ 2nd St., Elizabeth, N. J.

POPSKY, CHARLES H., Research Laboratory Assistant, Habirshaw Electric Cable Co., Yonkers, N. Y.

PORTER, ARTHUR S., Manager, Hamilton Office, Canadian General Electric Co., 603 Spectator Bldg., Hamilton, Ont., Can.

PORTER, LESLIE F., Engineer, Repeater Section, Western Electric Co. Inc., 463 West St., New York, N. Y.

POTTS, MELVIN, Electrical Engineer, Standard Steel & Bearings Inc., Plainville, Conn.

Potts Thomas R., Engineer, Southeastern Underwriters Association, Atlanta, Ga.

Puchstein, Albert F., Asst. Professor, Elec. Engg. Dept., Ohio State University, Columbus, Ohio.

Purdy, Fred R., Operating Dept., United Electric Light & Power Co.; res., 601 W 181st St., New York, N. Y.

Putnam, Arthur D., Engineer, Worcester Electric Light Co., 11 Foster St., Worcester, Mass.

Read, Lance, Service Engineer, Westinghouse Electric & Mfg. Co., 32 S. Peoria St., Chicago; res., 534 N. Court St., Rockford, Ill.

Redding, William Chester, Engineer, Western Electric Co. Inc., 463 West St., New York, N. Y.

Reed, John W., Sales Engineer, Holtzer-Cabot Electric Co., 627 Metropolitan Life Bldg., Minneapolis, Minn.

Rees, Raymond J., Asst. Electrician, The Great Western Sugar Co., Brighton, Colo.

Reid, William M., Meter Inspector, Hydro-Electric Power Commission of Ontario, 8 Strachan Ave., Toronto, Ont., Can.

Reier, George Conrad, Development & Research Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

Reneker, Robert Lee, Electrical Engineering Dept., Ford Motor Co., Detroit; res., Royal Oak, Mich.

Reynolds, Frank J., Engineer, Hartford Electric Light Co., 266 Pearl St., Hartford, Conn.

Ribal, E. A. H., Secretary, Dearborn Electrical Construction Co. Inc., 27 West Kinzie St., Chicago, Ill.

Richey, Nelson R., Electrical Engineer, General Electric Co., Fort Wayne, Ind.

Riggs, Albert C., Supt., Line Construction, Puget Sound Power & Light Co., 7th & Olive Sts., Seattle, Wash.

Roberg, Philip, Research Engineer, National Carbon Co., Cleveland; res., 1377 Lakeland Ave., Lakewood, Ohio.

Roberts, Bruce W., Engineering Dept., Puget Sound Traction, Light & Power Co.; res., 813 W. 64th St., Seattle, Wash.

Robinson, Benjamin, Chief Electrician, Bristol Brass Corp., 122 6th Ave., Bristol, Conn.

Robinson, Harry W., Sales Engineer, Sprague Electric Works of General Electric Co., 1213 American Bldg., Baltimore, Md.

Robinson, Isaac R., Asst. Engineer, Public Works Dept., Wellington, New Zealand.

Rocky, Basil S. S., Transformer Engineer, Apparatus Sales Dept., Canadian General Electric Co. Ltd., 212 King St. West, Toronto, Ont.

Rockey, James K., Long Lines Engineering Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.; res., Ridgefield Park, N. J.

Rosenfeld, Benjamin, Sales Engineer, Roland Electrical Co.; res., 3201 Presbury St., Baltimore, Md.

Ross, Walter R., Asst. Design Engineer, Philadelphia Electric Co., 1000 Chestnut St.; res., 1800 N. Broad St., Philadelphia, Pa.

Rothwell, Hugh D., Asst. Engineer, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.

Rubin, Maurice, Electrical Engineer, Public Service Commission, 1st District, 49 Lafayette St., New York. N. Y.

Rust, James E., Electrical Engineer, Kohler Bros., 111 N. Jefferson Ave., Chicago; res., 328 Prairie Ave., Park Ridge, Ill.

Ruxton, Thomas B., Leadingman Electrician, U. S. Navy Yard; res., 20 Columbia St., Portsmouth, N. H.

Salmon, S. H., Jobber & Dealer in Electrical Supplies, 50 Obispo, Havana, Cuba.

Sanders, Walter J., Asst. Operating Engineer, City of Chicago, 405 W. Chicago Ave; res., 6228 S. Winchester Ave., Chicago, Ill.

Saville, John A., Sales Engineer, Western Electric Co., Inc. Chicago; res., 216 Fourth St., Wilmette, Ill.

Schafer, J. Peter, Research Engineer, Western Electric Co., 463 West St., New York, N. Y.

Schiller, Avery, R., Electrical Engineer, John A. Stevens, 904 Sun Bldg., Lowell, Mass.

Schmid, Charles F., Technical Asst., Electrical Testing Laboratories, 80th St. East End Ave., New York; res., 475 Gramatan Ave., Mt. Vernon, N. Y.

Schoening, Edward M., Electrical Foreman, Pullman Co.; res., 9222 Houston Ave., Chicago, Ill.

Schuler, Louie L., Engineer, Haughton Elevator & Machine Co.; res., 405 Prescott St., Toledo, Ohio.

Schuler, William A., Engineer, Western Electric Co., 463 West St.; res., 32 St. Nicholas Place, New York, N. Y.

Schwaner. Robert M., Inspecting Engineer, Westinghouse Elec. & Mfg. Co.; res., 1937 Daly Ave., New York, N.Y.

Scofield, Robert W., Electrical Engineer, American Tel. & Tel. Co., 195 Broadway, New York; res., 267 Halsey Street, Brooklyn, N. Y.

Scott, Fred J., Meter Tester & Armature Winder, Washington Water Power Co.; res., 2809 W. Mallon Ave., Spokane, Wash.

Seaman, George B., Construction Engineer, General Electric Co., Monadnock Bldg.; res., 11141 Esmond St., Chicago, Ill.

Seefield, Charles W., Clerk, Meter Dept., Puget Sound Power & Light Co.; res., 2 Smith St., Seattle, Wash.

Seely, Roy A., Engineer, Western Electric Co., 463 West St.; res., 611 W. 114th St., New York, N. Y.

Seem, Warren P., Gen. Supt. of Throwing, The Schwarzenbach Huber Co., Altoona, Pa.

Seuel, F. J. P., Engineer, Underground Extensions, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

Sexton, Carlton H., Engineering Dept., Western Electric Co., Inc., 463 West St., New York, N. Y.

Sharpe, Victor L., Foreman, Sprague Electric Works of General Electric Co., Bloomfield; res., 739 Springdale Ave., E. Orange, N. J.

Shaw, John W., Assistant Superintendent of Station Repairs, Hydro-Electric Power Commission of Ontario, Merchants Bank Bldg., Hanilton, Ont.

*Shea, Timothy E., Instructor in Physics, Massachusetts Institute of Technology, Cambridge; res., 49 Worcester St., Newton Upper Falls, Mass.

Sheatsley, George W., Electrician, Ozark Coal Mining Co., Cumberland; res., 1210 South 8th St., Tacoma, Wash.

Shipp, James E., Apparatus Sales Dept., Motor Section, Canadian General Electric Co., Ltd.; res., 456 Gladstone Ave., Toronto, Ont.

*Shirk, William B., Student, Lehigh University, Bethlehem; res., 125 S. 6th St., Lebanon, Pa.

Shore, Sydney E., Sr., Chief Load Dispatcher, Georgia Railway & Power Co., 24 E. Alabama St., Atlanta, Ga.

Simons, Robert, Methods Assistant, The Bell Tel. Co. of Pa.; res., 921 N. 28th St., Philadelphia, Pa.

Sims, William F., Field Engineer, Generating Stations, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

*Sinclair, Bliss G., Chief Electrician, American Nitrogen Products Co., La Grande, Wash.

Sinclair, Ovid E., Inspector, Public Service Co. of Northern Illinois, Crystal Lake, Ill.

Singer, Fred J., Asst. Operator, Puget Sound Power & Light Co., 7th & Olive Sts., Seattle, Wash.

Skibbe, Fred F., Electrical Draftsman, Manufacturing Dept., Pullman Co.; res. res., 7245 Champlain Ave., Chicago, Ill.

Skrainka, Walter J., Electrical Engineer, Wagner Electric Mfg. Co.; res., 4235 Lindell Blvd., St. Louis, Mo.

Smalley, David D., Div. Supt., Midland Countiies Public Service Corp., Santa Maria, Cal.

Smedley, Harry J., Valuation Dept. The Byllesby Engineering & Management. Corp., Continental & Commercial Bank Bldg.,Chicago, Ill.

Smith, A. Z., Electrical Contractor, 905 Court A, Tacoma Wash.

Smith, Benjamin M., General Engineering Laboratory, General Electric Co., Schnectady, N. Y.

Smith, Frederic, Div. Supt. of Construction, The Pacific Tel. & Tel. Co., 835 Howard St., San Francisco, Cal.

Smith, Fred W., Electrical Engineer, The Robbins & Myers Co., Springfield, Ohio.

Smith, James C., Commercial Manager, The Virginian Power Co., Charleston, W. Va.

Smith, Marvin W., Designing Engineer. Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1105 Trenton Ave., Wilkinsburg, Pa.

SMITH, ROBERT W., Engineering Asst., Engineering Dept., Bell Telephone Co. of Pennsylvania, 416 7th Ave., Pittsburgh, Pa.

SNOOK, WARD H., Secretary & General Manager, Paulding Home Telephone Co., Paulding, Ohio.

SNOW, FRANK S., Electrical Draftsman, U. S. Navy Yard; res., 170 Gate St., Portsmouth, N. H.

SNOW, WILBER C., Power Solictor, City of Seattle Lighting Dept., 204 County-City Bldg.; res., 418 24th Ave. South, Seattle, Wash.

SNYDER, FRED H., Electrical Operating Engineer, City of Chicago, 405 W. Chicago Ave., Chicago, Ill.

SOKOLOFF, MAX N., 911 E. 178th St., New York, N. Y.

SPENCER, WARREN G., Electrical Engineer, General Electric Co., 627 State Mutual Bldg., Worcester, Mass.

SPINNEY, PARKER T., Efficiency Engineer, Habirshaw Electric Cable Co., 320 Warburton Ave., Yonkers, N. Y.

SPITLER, WESLEY N., Electrical Designer, Sessions Engineering Co., 22 W. Monroe St., Chicago; res., Mt. Greenwood, Ill.

SPOONER, JOHN W., Electrical Engineer, Sessions Engineering Co., 1203 Majestic Bldg., 22 W. Monroe St., Chicago, Ill.

STAMM, OTTO E., Chief Tester, New York Edison Co., 92 Vandam St., New York, N. Y.

STANG, WILLIAM H., Inspection Engineer, Lehigh Power Securities Corp., Hunsicker Bldg., Allentown, Pa.

STARIN, MARTIN W., Special Apprentice, Van Nest Electrical Shops, N. Y., N. H. & H. R. R.; res., 2078 Boston Road, New York, N. Y.

STEADMAN, HAROLD C., Sales Engineer, Cutler-Hammer Mfg. Co., 1238 Guardian Bldg., Cleveland, Ohio.

STEELE, FRANK W., A. C. Engineering Dept., British Thomson-Houston Co. Ltd.; res., 133 Murray Road, Rugby, England.

STEVENS, EARL E., Electrical Testing Engineer, Commonwealth Edison Co., 28 N. Market St., Chicago, Ill.

STODDARD, FRED M., Chief Electrician, South Covington & Cincinnati Street Railway Co., Cincinnati, Ohio.

STRATTON, WILLIAM D., Engineer, Western Electric Co.Inc., 463 West St.; res., 609 W. 115th St., New York, N. Y.

STRONG, ALBERT E., Chief Inspector, Kellogg Switchboard & Supply Co., Adams & Aberdeen Sts., Chicago, Ill.

SUDDUTH, ARTHUR L., Instructor, School of Engineering of Milwaukee; res., 163 Mason St., Milwaukee, Wis.

SUERTH, JOSEPH A., Supervising Electrician, Peoples Gas, Light & Coke Co., 122 S. Michigan Ave., Chicago, Ill.

SUMMERFIELD, SIDNEY C., Central Office Engineering, Western Electric Co., Hawthorne Station, Chicago, Ill.

SUTHERLAND, GEORGE, Engineer, Electrical Engineering Div., Stone & Webster Engg. Corp., 147 Milk St., Boston, Mass.

SWIFT, HERBERT A., Estimator of Station Construction, Toronto Hydro-Electric System, Duncan & Nelson Sts., Toronto, Ont., Can.

SYKES, STANTON B., Control Specialist, General Electric Co., 1026 Monadnock Bldg., Chicago, Ill.

TAVENNER, GEORGE T., Sales Engineer (Electrical), Lincoln Electric Company, 3215 Singer Bldg., New York, N. Y.

TEMPLE, ELMER J., Electrical Engineer, General Electric Co.; res., 20 Stratford Ave., Pittsfield, Mass.

TERRY, WILLIAM H., Electrical Draftsman, Generating & Substation Design, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

THOMPSON, HARRY B., Operator, Utah Power & Light Co., Grace, Idaho.

THOMPSON, ROBERT W., Manager & Secretary, Thompson & Castelton, Inc., 316 1st Ave. South, Seattle, Wash.

*THOMPSON, STEPHEN W., Sales Engineer, Century Electric Company, St. Louis, Mo.

TILLINGHAST, THEO. V., Chief Clerk, P. L. & M. Dept., Pullman Co., Pullman Trust & Savings Bank, Chicago, Ill.

TILTON, HENRY O., Sales Agent, General Electric Co., 340 Main St., Worcester, Mass.

TOYER, HARRY EDWARD, Asst. Supt., Hydro Plant, Winnipeg Electric Railway Co., Pinawa, Manitoba.

TRAFERT, ARCHIE WILSON, Railway Sales Agent, General Electric Co., Colman Bldg., Seattle, Wash.

TRACY, EDWARD R., Switchboard Engineer, The Pacific Tel. & Tel. Co., 503 Sheldon Bldg., San Francisco, Cal.

TRUEAX, CLYDE P., Electrical Engineer, Condron Co., 1433 Monadnock Bldg.; res., 5633 Cottage Grove Ave., Chicago, Ill.

TURNER, EDWARD E., Asst. Chief Engineer, Lehigh Valley Light & Power Co., Hauto, Pa.

UNDERHILL, ARTHUR W., JR., Engineering Dept., Niagara, Lockport & Ontario Power Co., 1638 Marine Bank Bldg., Buffalo, N. Y.

UPSON, CLAIR P., Electrical Draftsman, Tennessee Coal, Iron & R. R. Co.; res., 802 Tuscaloosa Ave., Birmingham, Ala.

VAN BUSKIRK, JAMES, District Manager, Moloney Electric Co., 431 So. Dearborn St., Chicago, Ill.

VANHALANGER, L. JOSEF, Electric Service Engineer, Westinghouse Elec. & Mfg. Co.; res., 2103 Lawrence Ave., Chicago, Ill.

VAN RENNES, CORNELIS, Designing Engineer, Delco Light Co., Taylor St.; res., 35 Illinois Ave., Dayton, Ohio.

VANSANT, SOMERS S., Electrician in Charge, American Sugar Refinery Co.; res., 225 Warren St., Jersey City, N. J.

VIOL, WALTER E., Telephone Equipment Engineer, Western Electric Co., 463 West St., New York, N. Y.

WAGNER, CHARLES F., Research Electrical Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh; res., 812 Cedar Ave., N. S., Pittsburgh, Pa.

WALKER, FREDERICK, Draftsman-Engineer, Canadian Westinghouse Co., Hamilton, Ont., Can.

WALKER, RICHARD, Inspector, Engineering Dept., South Eastern Underwriters Association, Atlanta, Ga.

WALL, J. VAN RENSSELAER, Engineer, Tel. Systems Development Organization, Engineering Dept., Western Electric Co. Inc., 463 West St., New York, N. Y.

WALLACE, GEORGE A., Lecturer in Electrical Engineering, McGill University, Montreal, Canada.

WALLIS, CHARLES R., Sales Agent, General Electric Co., 609 Colman Bldg., Seattle, Wash.

WANAMAKER, ERNEST, Electrical Engineer, Chicago, Rock Island & Pacific Railway La Salle Street Station, Chicago, Ill.

WARNER, LESLIE THOMAS, Electric Light Dept., Town Hall; res., 289 Old Canterbury Road, Dulwich Hill, Sydney, N. S. W., Aus.

WEAN, LINCOLN E., Asst. Elec. Designer, Philadelphia Electric Co.; res., 1947 N. Camac St., Philadelphia, Pa.

WEEKS, ARTHUR W., Assistant Engineer, Gas Rectifiers, General Electric Co., W. Lynn; res., 9 Redington St., Swampscott, Mass.

WEST, CHARLES P., Draftsman, Cleveland Railway Co., Cedar Ave. Power House, Cleveland, Ohio.

WHITE, B. STUART, Electrical Supt., Fraser Cos., Ltd., Edmundston, N. B., Canada.

WINTER, BOYD W., Salesman, Westinghouse Elec. & Mfg. Co., Alaska Bldg., Seattle, Wash.

WINTERS, WALTER N., Plant Electrician, Gorden Oil & Gas Co., W. Tulsa, Okla.

WISWELL, FREDERICK G., Chief Draftsman, Puget Sound Power & Light Co., 605 Electric.Bldg., Seattle, Wash.

WOLF, HERBERT J., Assistant Plant Engineer, Pratt & Whitney Co., Hartford; res., 98 Gregory St., New Haven, Conn.

WOOD, ERNEST B., Instructor of Physics, Pratt Institute, Brooklyn, N. Y.

WOOD, HERBERT A., Electrical Engineer, Railway Dept., Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.

WOOTTON, WILLIAM L., Graintex Company, Inc., 170 Madison Ave., New York, N. Y.

WRIGHT, GEORGE T., Student, Electric Traction Dept., L. B & S. C. Railway, Norwood Junction, London, Eng.

WRIGHT, PAUL L., Engineer, Western Electric Co. Inc., 463 West St.; res., 126 W. 104th St., New York, N. Y.

WRIGHT, VIRN J., Electrical Draftsman, U. S. Navy Yard; res., 52 Daniel St., Portsmouth, N. H.

YOSHIMURA, GEORGE U., Draftsman, Control Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

YOUNGER, MARTIN L., Electrical Engineer, General Electric Co., 19 Maud St., Pittsfield, Mass.

*ZINN, MANVEL K., Research Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

ZURICK, MARTIN J., Chief Electrician, The Great Western Sugar Co., Brighton, Colo.

Total 440

*Former enrolled students.

ASSOCIATES RE-ELECTED JUNE 30, 1920

BENTZ, HENRY C., Manager, Appliance Dept., St. Paul Electric Co.; res., 637 Marshall Ave., St. Paul, Minn.

CAHOON, WILLIAM H., Electrical Designer, Perin & Marshall, 50 Trinity Place, New York; res., 10 Hillside Court, Jamaica, N. Y.

CONNELL, C. W., Captain, A. S. A., U. S. Army, 1748 Q St. N. W., Washington, D. C.

DUNN, EDWARD J., General Superintendent, Indiana Utilities Co., 215 W. Maumee St., Angola, Ind.

ELLYSON, DOUGLAS WALKER, Electrical Engineer, General Electric Co., Monadnock Bldg., Chicago, Ill.

GIBBS, HARRY T., Ra lway Sales Engineer, Canadian Westinghouse Co., 1207 Bank of Hamilton Bldg., Toronto, Ont.

MCADAM, CLARENCE E., Engineer in Charge of Power Plant, Visayan Refining Co., Cebu, Cebu, P. I.

TOLMAN, CLARENCE M., Electrical Engineer, Moose Mountain, Ltd., Sellwood, Ontario, Can.

VAITSES, GREGORY S., Chief Electrical Tester New York Shipbuilding Corp., Camden; res., 308 Boulevard, Pitman, N. J.

MEMBERS ELECTED JUNE 30, 1920

BENHAM, FRANK A., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

BURROWS, ROBERT PENN, Secretary & Treasurer & Sales Engineer, The Electric Sales& Engineering Co., 815-23 Prospect Ave,. Cleveland, Ohio.

CARROLL, PENN LEARY, Lieut-Comdr., U. S. Navy; Chief Engineer, U. S. S. New Mexico, Navy Dept., Washington, D. C.

CHU, YU MAI, Asst. Engineer, Acting Chief Engineer, Kwongtung Tramway Co., The Bund, Canton, China.

CLAMER, GUILLIAM H., 1st Vice-Pres. & Secy., The Ajax Metal Co., Frankford Ave. & Richmond St., Philadelphia, Pa.

CRAIG, BERRYWICK S., Electrical Engineer, The Texas Co., Port Arthur, Texas.

EWING, SYDNEY E. T., Consulting Mechanical & Electrical Engineer, Consolidated Mines Selection Co. Ltd., Johannesburg, S. Africa.

GOODWIN, ALBERT G. T., Power Plant Engineer, Broken Hill Associated Smelters, Port Pirie, S. Australia

GRANT, HENRY W., Supt. of Railway, Pacific Northwest Traction Co. & Puget Sound International Railway & Power Co., Everett, Wash.

GUTHORN, SEYMOUR L., Electrical Engineer, Perin & Marshall, 2 Rector St. New York, N. Y.

HUIE, OLIVER J., Chief Engineer, Southern Bell Tel. & Tel. Co. & Cumberland Tel. & Tel. Co. Inc., 78 Pryor St., Atlanta, Ga.

PEARSON, EDGAR FORD, Electrical Engineer, Northwestern Electric Company, Portland, Oregon.

POPE, HARRY B. Chief Substation Operator, Brooklyn Edison Co., Inc.; res., 34 Jefferson Ave., Brooklyn, N. Y.

SANDT, ROBERT A., Chief Engineer, Maxwell Engineering & Manufacturing Co., 61 Broadway, New York, N. Y.

SHEARER, HAROLD H., Engineer, General Engineering Staff' American Tel. & Tel. Co., 195 Broadway, New York, N. Y

STEPHENSON, LEIGH J., Private work on Electric Motors & Control Systems, 2157 West 107th St., Chicago, Ill.

TICE, FRANK H., Engineer & Estimator, George Woodward, Jr., 1723 Sansom St., Philadelphia, Pa.

WIDMARK, LAWRENCE E., Chief Engineer, Star Electric Motor Co., 124 Miller St., Newark, N. J.

WITHINGTON, SIDNEY, Electrical Engineer, N. Y. N. H. & H. R. R.; res., 86 Linden St., New Haven, Conn.

MEMBERS RE-ELECTED JUNE 30, 1920

BOYDEN, DAVIS S., Asst. Superintendent, Electrical Engineering Dept., The Edison Electric Illuminating Co. of Boston, 39 Boylston St., Boston, Mass.

RAE, FRANK B., Consulting Engineer, Avenue Bldg., 4500 Euclid Ave., Cleveland, Ohio.

TRANSFERRED TO GRADE OF FELLOW JUNE 30, 1920

BIBBINS, JAMES R., Supervising Engineer, The Arnold Co., Chicago, Ill.

BYLLESBY, HENRY M., President, H. M. Byllesby Co.; President Standard Gas & Electric Co., Chicago, Ill.

CALDWELL, HARRY L., Engr. of Elec. Distribution, Public Service Co. of Northern Illinois, Chicago, Ill.

CRAVATH, JAMES R., Member of firm, Fowle & Cravath, Chicago, Ill.

DEL MAR, WILLIAM A., Chief Engineer, Habirshaw Electric Cable Co., New York, N. Y.

ELLS, FREDERICK W., Chief Engineer, Northwestern Mfg. Co., Milwaukee, Wis.

FRASER, DANIEL M., Estimating Engineer, Canadian General Electric Co. Ltd., Toronto, Ont.

GEAR, HARRY B., Engr. of Distribution, Commonwealth Edison Co., Chicago, Ill.

HALL, CHESTER I., Engineer, Experimental Laboratory, General Electric Co., Fort Wayne, Ind.

KING, ARTHUR C., President, Illinois Appraisal Co., Chicago, Ill.

MILTON, TALIAFERRO, Manager, Chicago Office, Electric Storage Battery Co., Chicago, Ill.

MORTENSEN, NIELS L., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

MORTENSEN, SOREN H., Electrical Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

MOUNTAIN, JOHN T., Asst. to Chief Operating Engineer, Commonwealth Edison Co., Chicago, Ill.

REINHARD, LOUIS F., Chief Engineer, Mechanical Appliance Co., Milwaukee, Wis.

SCHWEITZER, EDMUND O., Chief Testing Engineer, Commonwealth Edison Co., Chicago, Ill.

SNOOK, H. CLYDE, Electrical Engineer, Western Electric Co., New York, N. Y.

WALLACE, JOHN N., Engineer in Australasia, Western Electric Co. Ltd., Wellington, N. Z.

TRANSFERRED TO GRADE OF MEMBER JUNE 30, 1920

ACKLAND, EUSTACE W., Managing Director, National Electrical & Engineering Co. Ltd., Wellington, N. Z.

ADAMS, HARRY H., Supt. Shops & Equipment, Chicago Surface Lines, Chicago, Ill.

ALLEN, N. L., Chief Electrical Engineer, American Zinc Lead & Smelting Co., Mascot, Tenn.

ANNETT, FRED A., Associate Editor, "Power," New York, N. Y.

BACON, FRANK R., President, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

BAKER, HENRY S., In Charge Detail Apparatus, Ontario Power Co., Niagara Falls, Ont.

BENSON, ROBERT J., Power Engineer, Wagner Electrical Mfg. Co., St. Louis, Mo.

BELL, WILLIAM I., Mechanical & Electrical Engineer, South Park Commissioners, Chicago, Ill.

BOOTH, WILLIAM K., Secretary & Chief Engineer, Booth Electric Furnace Co., Chicago, Ill.

BOWMAN, DONALD, Engineer of Apparatus & Materials, Commonwealth Edison Co., Chicago, Ill.

BRACK, G. S., Electrical Engineer, The Sanitary District of Chicago, Chicago, Ill.

BRITTON, JOHN A., Vice-President & General Manager, Pacific Gas & Electric Co., San Francisco, Cal.

BROWN, CARLTON E., Meter Engineer, Commonwealth Edison Co., Chicago, Ill.

BURR, FRANK D., Power Engineer, Denver Gas & Electric Light Co., Denver, Colo.

CLINGERMAN, BYRON H., Managing Power Engineer, B. F. Goodrich Co., Akron, O.

CRELLIN, EARLE A., Electrical Engineer with Leland S. Rosener, San Francisco, Cal.

CURTIS, LESLIE F., Asst. Professor of Electrical Engineering, University of Washington, Seattle, Wash.

D'HUMY, FERNAND E. Central Office Engineer, Western Union Telegraph Co., New York, N. Y.

DU VALL, W. CLINTON, Associate Professor of Electrical Engineering, University of Colorado, Boulder, Colo.

EDWARDS, STANLEY R., Editor, "Telephony," Chicago, Ill.

FLANDERS, MILTON M., Charge Dept. of Electrical Tests, Bliss Electrical School, Washington, D. C.

FLEET, ARTHUR H., Manager, Specialty Dept., Cutler-Hammer Mfg. Co., Milwaukee, Wis.

FOX, EDWIN G., Electrical Engineer, Steel & Tube Co. of America, Indiana Harbor, Ind.

GILLESPIE, FONTAINE M., Chief Operating Engineer, Riegos y Fuerza del Ebro, Barcelona, Spain.

GILMAN, RALPH E., Electrical Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

GROWDON, JAMES P., Asst. General Superintendent, Northwestern Electric Co., Portland, Ore.

GUILFORD, WILLIAM S., Director, Griffin Engineering Co. Ltd., Capetown, S. Africa.

HUBBARD, FRANK H., Patent Attorney, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

JACKSON, WILLIAM A., President, W. A. Jackson Co., Chicago, Ill.

JAMES, WILLIAM F., Sales Engineer, Westinghouse Electric & Mfg. Co., Philadelphia, Pa.

JOHNSON, ALVIN W., Elec. Engr. in Charge General Construction, General Electric Co., Chicago, Ill.

KAMMERMAN, JOHN O., Asst. Professor of Electrical Engineering, University of Wisconsin, Madison, Wis.

LAUE, GILBERT E., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

LOCKE, DEAN J., Electrical Engineer, with Albert S. Richey, Worcester, Mass.

LODYGUINE, ALEXANDER, Inspector Incoming Electrical Material, Sperry Gyroscope Co., Brooklyn, N. Y.

LUNN, ERNEST, Chief Electrician, The Pulman Co., Chicago, Ill.

MAVITY, VICTOR T., Electrical Engineer, Braden Copper Co., Rancagua, Chile, S. A.

MCHENRY, MORRIS J., Manager, Walkerville Hydro-Electric System, Walkerville, Ont.

MORSE, ROBERT E., Engineer-in-Charge, Henry R. Kent & Co., Rutherford, N. J.

NYE, HENRY V., Special Sales Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

O'CONNOR, ALBERT, Manager, Switchboard Dept., Westinghouse Elec. & Mfg. Co., Boston, Mass.

OSTRANDER, JOHN K., Electrical Engineer, Dwight P. Robinson & Co., New York, N. Y.

PARKER, ROSS I., Apparatus Sales Dept., General Electric Co., Chicago, Ill.

PETROWSKY, JOHN F., Designing Engineer, A. C. Engineering Dept., Crocker-Wheeler Co., Ampere, N. J.

REINHARD, GUSTAV A., Asst. Chief Engineer, Mechanical Applicance Co., Milwaukee, Wis.

RUSSELL, FRANK J., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

SARA, RICHARD A., Partner, C. A. Sara, Montreal Que.

SCHOU, THEODORE, Chief Engineer, Ideal Electric & Manufacturing Co., Mansfield, O.

SEIBERT, WILLIAM J., Asst. Chief Electrician, General Electric Co., Erie, Pa.

SPENCER, FREDERICK A., Professor of Electrical Engineering, Norwich University, Northfield, Vt.

TODD, WILLIAM B., Asst. Electrical Engineer, E. I. du Pont de Nemours & Co., Wilmington, Del.

TUTTLE, ELBERT B., Asst. Engineer, Bell Telephone Co. of Pennsylvania, Philadelphia, Pa.

WADE, HENRY N., Development Engineer (Electrical), Cutler-Hammer Mfg. Co., Milwaukee, Wis.

WATERHOUSE, JAMES K., Supt. L. I. City District, N. Y. & Queens Electric Light & Power Co., Long Island City, N. Y.

WATT, GEORGE Y., Century Electric Co., St. Louis, Mo.

WHITNEY, RICH D., Associate Professor of Electrical Engineering, Syracuse University, Syracuse, N. Y.

WILKINSON, KENNETH L., Charge Foreign Wire Relations, American Telephone & Telegraph Co., New York, N. Y.

WURTH, WILLIAM, Engineer Statistics, The Peoples' Gas Light & Coke Co., Chicago, Ill.

WYNNE, VALENTINE C., Consulting Engineer, Albany, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candiadates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before August 31, 1920.

Austin, Eugene H., Wilkes Barre, Pa.
Bauer, Ernst, Niagara Falls, N. Y.
Blodgett, Dan A., Flint, Mich.
Brualla, Francis, New York, N. Y.
Bryan, Frank A., Jr., Ft. Wayne, Ind.
Buys, Orville, Pittsburgh, Pa.
Caputo, Nicholas J., Brooklyn, N. Y.
Carr, William W., Wenatchee, Wash.
Chapman, Penrose E., (Fellow), St. Louis, Mo.
Chesterman, Francis J., Philadelphia, Pa.
Colt, Frank B., New York, N. Y.
Cootes, John C. R., Latouche, Alaska.
Denyes, Percy C., Cambellford, Ont.
Dick Herman J., Shelby, Ohio
Dobson, Harry V., Stockton, Cal.
Fitzsimons, Thomas, Philadelphia, Pa.
Gilmore, Martin L., Toronto, Ont.
Green, Leroy S., Baltimore, Md.
Greenhut, Frederick W., New York, N. Y.
Griffith, Lafayette F., (Member), Little Rock, Ark.
Guha, Devendra N., Newark, N. J.
Harlan, Earl, Fresno, Cal.
Hay, H. Harvey, Yonkers, N. Y.
Hayward, Charles L., St. Louis, Mo.
Hazeltine, Harold L., Pittsburgh, Pa.
Hiddleson, William A., Bristol, Tenn.-Va.
Hubbard, George W., Chicago, Ill.
Lewinson, Leonard J., (Member), New York, N. Y.
Lohr, Frederick T., Gouverneur, N. Y.
Lyons, A., Cincinnati, Ohio
Manegold, John R., Milwaukee, Wis.
Martin, Harrison A., Asheville, N. C.
Marvin Harry B., Schenectady, N. Y.
Miller, Herbert E., (Member), Pullman, Ill.
Moray, Thomas H., (Member), Salt Lake City, Utah
Morrison, Hal, Atlanta, Ga.
Nicholas, Frank R., Seattle, Wash.
Nichols, Albert W., St. Louis, Mo.
Noyes, Maxwell E., Pittsburgh, Pa.
O'Connor, Hugh, Cincinnati, Ohio
Page, Samuel T., Philadelphia, Pa.
Plimpton, Bentley A., (Member), Victor, N. Y.
Polk, J. Lane, Jr., Altoona, Pa.
Poole, Homer J., Los Angeles, Cal.
Powel, Charles A., (Member), E. Pittsburgh, Pa.
Royer, Walter D., Pittsburgh, Pa.
Spray, George C., E. Pittsburgh, Pa.
Stone, Ellery W., (Member), San Francisco, Cal.
Thrane, C. Harold, Los Angeles, Cal.
Travis, Julian T., Kansas City, Mo.
Van Wickle, Charles F., Hackensack, N. J.
Vilstrup, Asger, Vancouver, B. C.
Voss, Henry L., (Fellow), Terre Haute, Ind.
Wagner, Gerald J., (Member), Grand Rapids, Mich.
Warrington, C. M., Coshocton, Ohio
Werner, Pierre R., New York, N. Y.
Wood, Homer E. Tacoma, Wash.
Total 57.

Foreign

Arimura, Shinnosuke, Marunouchi Kojimachuku, Tokyo, Japan
Bannister, Albert, Manchester, Eng.
Blackwood, Archibald G., Lake Coleridge, N. Z.
Byng, Edward S., (Member), N. Woolwich, London, Eng.
Dnegro, Arthur P., Santiago, Chile
Elliott, Lee M., Jatibonico Prov., Camaguey, Cuba
Fielder, Ebenezer, Christchurch, N. Z.
Frigon, Augustin, Paris, France
Gibbons, Walter J., Rotorua N. Z.

Yoshikichi, Furukawa, Fukuoka, Japan
Total 33.

OFFICERS of A. I. E. E. 1920-1921

PRESIDENT.

(Term Expires July 31, 1921
A. W. BERRESFORD

JUNIOR PAST-PRESIDENTS.

(Term expires July 31, 1921)	(Term expires July 31, 1922)
COMFORT A. ADAMS	CALVERT TOWNLEY

VICE-PRESIDENTS.

(Terms expire July 31, 1921)

CHARLES S. RUFFNER	C. E. MAGNUSSON
CHARLES ROBBINS	E. H. MARTINDALE
L. T. ROBINSON	C. S. McDOWELL

MANAGERS.

(Terms expire July 31, 1921)	(Terms expire July 31, 1922)
WALTER A. HALL	WALTER I. SLICHTER
WILLIAM A. DEL MAR	G. FACCIOLI
WILFRED SYKES	FRANK D. NEWBURY

(Terms expire July 31, 1923)	(Terms expire July 31, 1924)
L. E. IMLAY	HAROLD B. SMITH
F. F. FOWLE	JAMES F. LINCOLN
L. F. MOREHOUSE	E. B. CRAFT

TREASURER	**SECRETARY**
(Term expires July 31, 1921)	
GEORGE A. HAMILTON	F. L. HUTCHINSON

HONORARY SECRETARY	**DIRECTOR OF THE LIBRARY**
RALPH W. POPE	HARRISON W. CRAVER

GENERAL COUNSEL

PARKER and AARON,
66 Broad Street, New York.

PAST PRESIDENTS—1884-1920

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
T. Commerford Martin, 1887-8.
Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
Schuyler Skaats Wheeler, 1905-6.
Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Kewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.
Calvert Townley, 1919-20.

*Deceased.

A. I. E. E. COMMITTEES

(The list of committees is omitted from this issue, as new appointments will be made for the administrative year beginning August 1.)

INSTITUTE REPRESENTATIVES

ON AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart. C. E. Skinner.

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon. Calvert Townley.

ON COMMISSION OF WASHINGTON AWARD

John Price Jackson. Charles F. Scott.

ON ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle, Charles S. Ruffner C. E. Skinner.

ON ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, E. W. Rice, Jr. Calvert Townley

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle, Samuel Sheldon, W. I. Slichter.

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett. W. R. Whitney.

ON SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

F. G. Agnew, F. C. Holtz, F. Conrad, A. E. Kennelly, S. G. Rhodes. F. P. Cox, Farley Osgood.

Surface Leakage as a Factor in Insulator Design

BY T. M. FEDER

Research Engineer, Jeffery-Dewitt Insulator Company.

The various factors influencing surface resistance and methods of increasing it, are discussed. It is shown that the most economical way of decreasing the leakage is the addition of properly proportioned corrugations on the under side of the flange or skirt. Typical computations are given, showing the approximate increase to be expected when corrugations are added.

ONE of the most important problems to be met by the insulator designer is that of surface leakage, or as it is sometimes, known, creepage. Under service conditions insulators acquire a coating film of moisture, or dust, or both, of a more or less conducting nature. This permits a current to pass from the line to ground over the surface of the insulators. The importance of this feature is well recognized by operating men and is a subject of live interest as evidenced by the attention paid to it in the engineering press. The magnitude of this current depends mainly on the material of the conducting film, and to some degree upon the character of the insulator glaze, since these may control the thickness of the deposited film.

Surface leakage is detrimental in three ways:

First, there is an actual loss of power due to the wasted current. This is very small when compared to the total power transmitted, but it is, nevertheless, one source of lost efficiency. In a long line many insulators are connected in parallel and the total leakage represents a considerable energy loss in a year.

Second, the leakage current causes heating of the insulators. This is a source of trouble on lines insulated by conventional type units, causing rapid expansion and contraction of the unit followed by cracking and consequent electrical failure.

Third, if the leakage be great enough, flash-over will occur, followed by a power arc. The flash-over in itself may not be destructive, but the power arc will heat and crack the thin section of the conventional unit. Regions are known wherein it is necessary to wash insulators quite frequently to avoid shut-downs from this effect.

It is thus seen that leakage should be reduced to as low a value as possible; in other words, the surface resistance of a unit should be made as great as possible without sacrificing other features of design.

It is the purpose of this paper to investigate the methods of increasing this surface resistance. It will be seen, however, that the subject is one which does not lend itself readily to analytical treatment. We can but derive some of the qualitative relations which show the most economical arrangement of the given amount of material for a maximum surface resistance.

From a consideration of the fundamental equation $R = \frac{\rho\, l}{a}$ wherein, $\rho =$ the resistance per unit volume; $l =$ length of conducting path and $a =$ area of conducting path, it is obvious that there is but one way of increasing the surface resistance for a given thickness and character of conducting film, and that is to increase l, the length of the path the current must traverse in creeping from electrode to electrode.

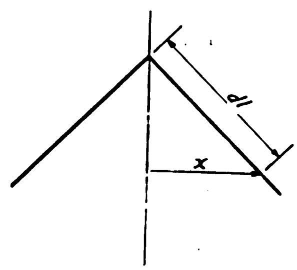

FIG. 1

It is also possible to decrease a, the area of the conducting film, but this change in a is an antagonistic function of other features of design, as it involves small unit diameters and consequently low flash-over values. The solution lies therefore, in adjusting l with as little increase in a as possible. This can be accomplished by either increasing the diameter or by the addition of corrugations and petticoats.

Consider the elementary conic insulator as shown in section in Fig. 1. Assuming a constant value ρ in the following discussions, the length of leakage path to any point on the surface is $d\, l$.

The radius to this point in the leakage path is x.

If t be the uniform thickness of the conducting layer, the cross-section of the conductor is $2\,\pi\, x\, t$.

$$\text{Total resistance } R = \frac{\rho\, l}{a} = \frac{\rho}{2\,\pi\, t}\int_0^L \frac{d\,l}{x} \qquad (1)$$

Given a unit with mathematical surfaces, equation (1) can be evaluated. For conventional types, however, this is impossible and the relation can best be shown by means of a surface resistance integral curve, as in Fig. 2. This being an integral curve, the area under the curve represents total resistance. For a unit not easily treated mathematically these areas are determined by measurement on the particular unit

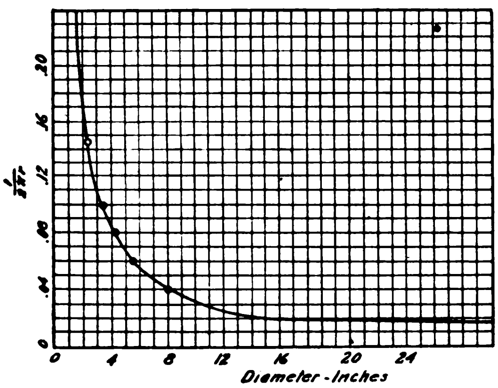

Fig. 2

studied. As shown by the shaded portions, the increase in total resistance gained by each equal increase in diameter becomes smaller and smaller as larger values of diameter are approached. Taking an extreme case, it is possible to increase the diameter without appreciably altering the value of R thereby. This shows how radically wrong it is to base the value of surface resistance on the diameter of the unit alone.

The explanation of this seeming paradox is quite

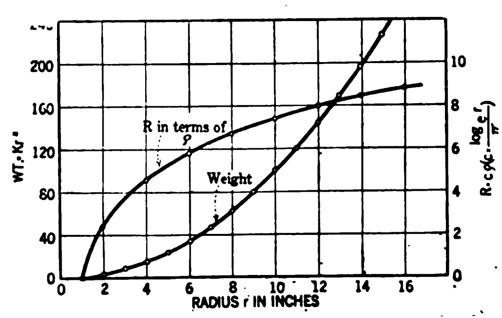

Fig. 3

simple. Surface resistance, as shown, is a function of length of leakage path and of diameter. As we increase length of leakage path l, we increase total resistance, but in so doing, as we increase the diameter, we decrease the total resistance, because of the effect of enlarging the area. Fortunately, as we increase the diameter the increase in length of leakage path attained increases the surface resistance at a greater rate than the increase in area of the conducting film lowers it. The effective increase in surface resistance follows a logarithmic curve, in accordance with the following equation:

Considering the upper surface only, $x = r = l$. Then equation (1) becomes

$$R = \frac{\rho}{2\,\pi\, t}\int_0^L \frac{d\,l}{x} = \frac{\rho}{2\,\pi\, t}\int_0^r \frac{d\,r}{r}$$

$$= \frac{\rho}{2\,\pi\, t}\log_e r$$

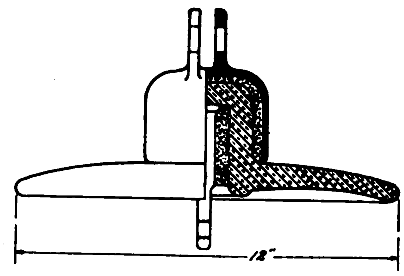

Fig. 4

For both upper and lower surfaces this relation becomes

$$R = \frac{\rho}{\pi\, t}\log_e r$$

For a given thickness of skirt the weight increases as the square of the radius. Graphically, these relations are shown in Fig. 3. Referring to this figure, assume a 12-in. disk (r = 6 in.) whose surface resistance we wish to increase by 20 per cent. For r = 6 in. $R = 0.58\,\rho$ and weight 36 K, where K is an arbi-

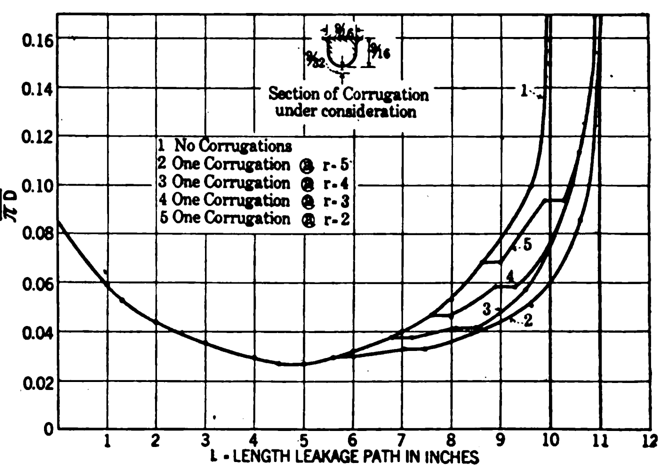

Fig. 5—Surface Resistance Integral Curves

Area under curves represents resistance of path

trary constant for the particular design. An increase of 20 per cent brings these values to $R = 0.696\,\rho$, r = 8.6 in., W = 74 K, an increase of 43 per cent in radius and 105 per cent in weight. Obviously the expense in material necessary to raise the surface resistance 20 per cent by increasing the diameter alone, is very high.

This procedure can be followed utilizing a conventional type unit as follows: Fig. 4 shows a conventional cap and pin type, 12-in. diameter suspension insulator with a smooth flange. The surface resist-

ance integral from this, computed by means of equation (1) is given as Curve (1) in Fig. 5.

In this curve, the resistance per inch of length of leakage path decreases from the cap to the end of the flange and then increases again on the under surface of the flange. The total area under the curve corresponds to $R = 0.50\ \rho$. Increasing this by 20 per cent means an addition of $0.1\ \rho$, corresponding in Fig. 3 to an increase in diameter of from 9 in. to 13 in. or 45.5 per cent and in weight, of 109 per cent, assuming the weight of cap and pin to remain constant. This is actually not true, since the weights of the cap and pin do increase with the diameter, making the increase in weight for a 20 per cent increase in surface by enlarging the diameter nearly 130 per cent.

It is obvious, then, that decreasing the surface leakage by making the unit larger, that is increasing the diameter alone, is a process of doubtful ecomonic value. There remains, then, the other scheme of increasing the surface resistance, and the one usually employed, *i. e.,* adding corrugations on the under side of the flange, increasing the length of leakage path without affecting the diameter of the unit.

Turning now to an investigation of the value of the corrugations and their best arrangement, assume the insulator shown in Fig. 5, placed on the under side of the flange at different radii.

The surface resistance integral curves for these conditions are shown in Fig. 5. The area under curve (1) as before mentioned, gives the resistance of the unit without any corrugations. Curve (2) is based on the same unit with one corrugation at a radius of 5 in.; curve (3) the same corrugation at a radius of 4 in., etc. Remembering that the length of leakage path is the same in all cases utilizing one corrugation, this shows strikingly that corrugations add an amount of resistance which varies inversely as the radius to the center line of the corrugation. The following table shows the approximate values of R.

Radius of corrugation	R	Increase in R	Per cent increase	Radius of smooth unit with equivalent R from Fig. 3
None	$0.50\ \rho$	....	....	4.5 in.
5 in.	$0.686\ \rho$	$0.186\ \rho$	37	8.6 in.
4 in.	$0.73\ \rho$	$0.23\ \rho$	46	9.6 in.
3 in.	$0.795\ \rho$	$0.295\ \rho$	59	11.8 in.
2 in.	$0.85\ \rho$	$0.35\ \rho$	70	14.4 in.

Curve (1) of Fig. 6 shows the relation between the percentage increase in total resistance offered by one corrugation, and the radius to the center line of the corrugation, a straight-line variation. Curve (2) of the same figure shows the percentage increase in total weight caused by a single corrugation at various radii. From these curves we see that R can be increased by 70 per cent and weight only by 8 per cent by adding one corrugation at a radius of 2 in. An attempt to attain this same increase by simply enlarging the diameter would result in an absurd unit. The equivalent addition in radius corresponding to one corrugation at different radii is shown in Fig. 7. It is interesting to note that for the unit referred to, this curve is a rectangular hyperbola. Thus one corrugation at 4-in. radius is equivalent to changing a 12-in. disk to one of 22-in. diameter, considering only resistance gained, with corresponding increase in weights of 16 per cent and 240 per cent respectively for the gain by corrugation and increased diameter.

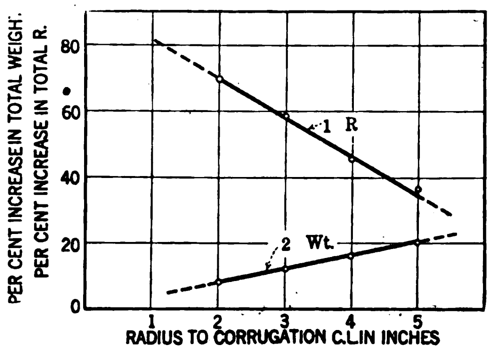

FIG. 6

The preceding discussion has purposely neglected the consideration of any of the other factors of design, of which surface resistance is but one item. However, certain conclusions present themselves which will hold good under any conditions of compromise found necessary by the designer. Surface leakage can be reduced in two ways; by a properly balanced design and by proper care in the field. A poorly designed unit may perform better than a well designed one in the matter of leakage if it is kept clean by periodic washing. In this respect, we must not forget that a deposited film of conducting material is cumulative. That is, a small film causes leakage and consequent heating of the insulator, which in turn evaporates any deposited moisture rapidly, causing it to leave its solid matter behind and so increasing the size of the original deposit and the leakage. A cold insulator will not evaporate the moisture rapidly, and will allow rain to wash the flange clear. The under surface, of course, will remain dirty until washed by the patrol. This is a function

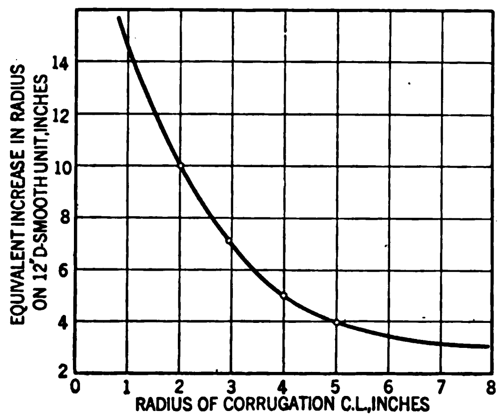

FIG. 7

of the operating engineer and not of the designer, but it is a great expense and it is the duty of all insulator designers to reduce as far as possible this burden on the operating engineer. It is only by a careful study of all such features of design that a rationally designed insulator can be produced that will meet the requirements of the operating engineer to the greatest degree.

The designer can do his part at the drafting table by making the diameter, and so the weight and cost, as small as consistent with other requirements, and the total resistance as large as possible, by the addition of properly proportioned corrugations of small diameter. The corrugations should be heavy enough to resist successfully shocks or power arc. Thin, deep corrugations are mechanically weak and should be avoided. A rationally designed unit has one advantage in surface resistance over the conventional type heretofore mentioned, which lessens the necessity for deep corrugations. In such a design, the body of the unit conforms with the flow lines of dielectric flux. Consequently the electrostatic stress along the surface of the body is everywhere tangential, and tends to throw off all particles of foreign matter which may otherwise lodge on it to form a conducting path. Thus the areas immediately around the electrodes are kept clean of all deposit and the surface resistance is a maximum. This is true of course, only in the consideration of the insulator in a dry condition.

It is hoped that this brief presentation of a very important factor in insulator design will lead operating engineers to a study of the distribution of material in insulator practise that will result in an improvement in the operating conditions of transmission lines in this respect.

Acknowledgments are due to Mr. W. D. A. Peaslee, Electrical Engineer of Jeffery-Dewitt Insulator Company for his many suggestions during the course of preparation of this paper.

FEDERAL ELECTRIC RAILWAYS COMMISSION

A unanimous report was made by the Federal Electric Railways Commission to President Wilson on August 24th, in which extensive reforms in the electric railway industry are recommended in order to restore public confidence and much needed credit. During the past year the electric railways have suffered severely and 48 companies went into receiverships. The War Labor Board made recommendations that the electric lines should increase wages $100,000,000 annually, but did not make any recommendation regarding increase of fares to meet the increasing costs of operation. The result is that the industry, representing six billions of capital, is in even more desperate condition than the steam railways.

The commission, which has been investigating the affairs of the railways for more than a year, makes some radical recommendations which are outlined in a dispatch to the New York *Times* as follows:

"Outstanding among the recommendations is that for the installation of the service-at-cost plan of operation. This plan, now operative in Cleveland, Cincinnati, Dallas, Montreal and other cities will, it is believed, remove the industry from the field of speculative gain, furnish rides at the lowest possible cost and restore credit and public confidence.

Primarily the plan provides for furnishing rides at actual cost, which shall govern the rate of fares, and for protecting the investor by guaranteeing a fixed return on an agreed valuation of his holdings.

Managements are advised that their primary duty is to serve the public with the highest efficiency at the lowest cost, with their cards face upward on the table, and not to use the industry as a means of obtaining profits beyond what may be necessary for upkeep, to pay a fair return upon the agreed value of the property and to secure the investment of funds further required.

The public duty is declared to be the supervision and control of railway properties, with the view of safeguarding the public interest and the allowance of such return upon the fair valuation of the property as may be agreed upon in the contract between the city and the company. By reason of such supervision the future attitude of the public should be one of friendliness and cooperation.

Employes it is said should have a living wage and humane hours of labor and working conditions, and a right to deal collectively with their employers, through committees or representatives of their own selection, but it is added that 'all labor disputes should be settled voluntarily or by arbitration and the award of such board should be final and binding on both parties.'

Other important declarations of the report are:

That public ownership and operation, generally speaking, are undesirable unless the results under private operation prove unsatisfactory, but the right of the public to own and operate all public utilities should be recognized and legal obstacles in the way of its exercise should be removed.

That extensions into outlying territory benefiting private property should be paid for by assessments on such property in proportion to the benefits received, and that the cost of such extensions should not be added to the valuation of the railroad property upon which a fair return is to be allowed.

That franchises should fix no limit as to the time they shall run nor the fares that may be charged.

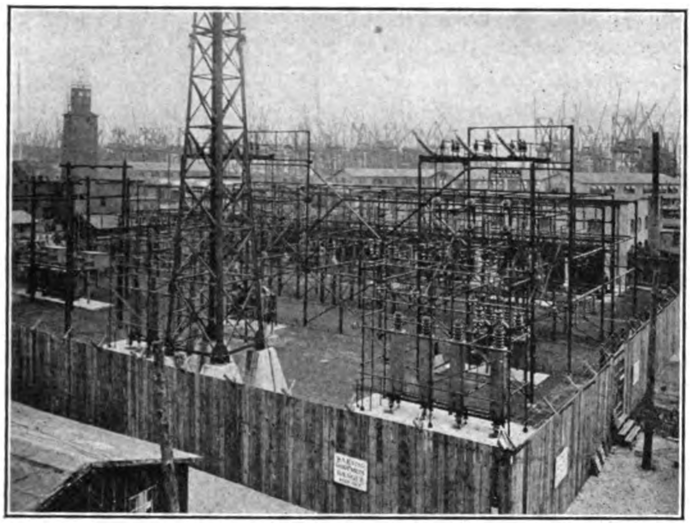
The commission emphasizes the importance of determining by arbitration or otherwise the fair value of the railway property 'as the basis for the financial return of the company,' and also as the basis upon which it may, if desired, be taken over by the municipality."

Features of the Substation at the Hog Island Shipyard

BY W. B. WEST

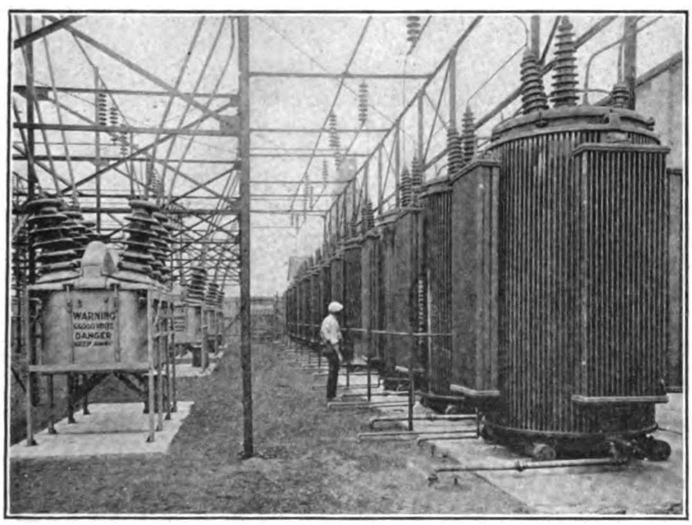
Hydroelectric Research Engineer, New York

THE Hog Island Shipyard, near Philadelphia, Pennsylvania, constructed as a war measure, and which is known all over the world as one of the largest shipyards in existence, is operated throughout by electrical power purchased from the Philadelphia



OUTDOOR 66,000-VOLT BUS STRUCTURE—MAIN SUBSTATION

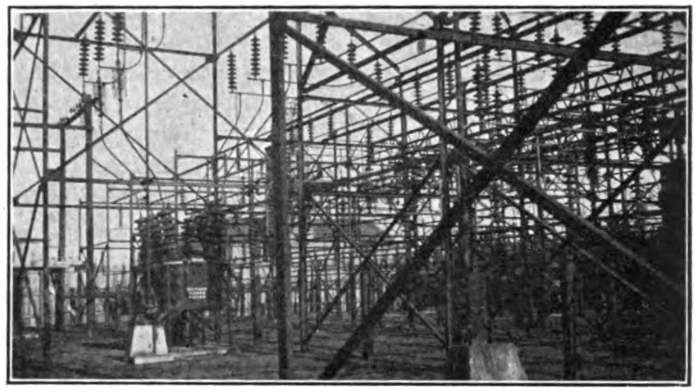
Electric Company and transmitted over a double-circuit, 66,000-volt stranded copper No. 00 tranmission line. There is also another single-circuit line operating at 13,000 volts. Both are three-phase circuits. At the main substation (shown in an accompanying illus-



TRANSFORMER BANK AND HIGH-TENSION OIL SWITCHES. MAIN SUBSTATION

tration) there are twelve General Electric transformers with a capacity of 2000 kv-a. each. The frequency throughout the system is 60 cycles per second. The primaries of the transformers are delta-connected, and the secondaries are Y-connected. Their temperatures were 55 deg. cent. when the writer was at the station in March, 1920. They are purely oil-cooled. Monthly tests are made of the oil in the transformers, and if the oil is below the 28,000 point it is filtered by a filter which is located on the interior of the substation. It too, is a standard G. E. type.

The 66,000-volt oil switches are arranged as shown in one of the illustrations. The bus structure is com-

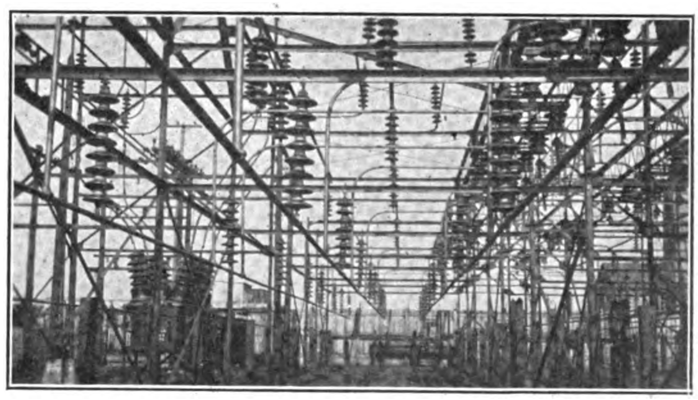


THE BUS STRUCTURE

posed of bronze coated pipes, 1¼ inches in diameter, suspended from eight-disk Ohio Brass insulators. The connections from all switches to the overhead bus structure are also 1¼-in. pipes.

The oil switches in the main substation are operated by electric motors ¼ h. p. each, using direct current at 110 volts pressure. This applies to three switches.

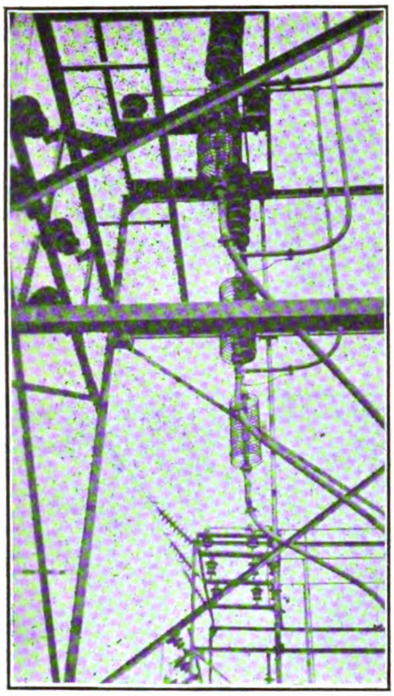
In the storage battery room there are 58 Gould storage cells which operate the oil switches and fire



A "GARDEN" OF ELECTRICAL EQUIPMENT

alarms. Each is capable of delivering 2½ volts maximum.

There is a private telephone exchange in the main substation. Trunk lines run from this P. B. X. exchange to the main telephone building. From the P. B. X. exchange telephone connections are made to the various plants throughout the yard which receive power from the main substation. Therefore, the op-



Details of Choke Coil Construction

eration of the entire system is not only under the control of the load dispatcher in the main substation, but men in the main office may also communicate with operators at the various plants.

From the main substation power is distributed to the seven air compressor stations at a voltage of 4150, and to the pumping stations and other utilities. The compressor plants supply compressed air for the operation of riveters and other structural devices.

Construction was carried on under the greatest imaginable handicaps, as to isolation of location from transportation, bad drainage, weather conditions, and other causes coincident with the construction of the shipyard which was being carried on at the same time.

E. T. Smith who is Electrical Superintendent has immediate supervision of this station's operation. F. G. O'Neil is in charge of the Utilities Department.

High-Frequency Iron Losses

BY THOS. SPOONER

Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Data are presented giving the iron losses for five-mil, 4 per cent silicon steel sheet for a range of frequencies from 5000 to 50,000 cycles per second. An approximate separation of hysteresis and eddy current losses is made showing the result of skin effect on these losses.

A method of test is described which if desired could be used over a much wider range of frequencies than those indicated. The source of high-frequency supply was a new type of arc oscillator.

The probable accuracy of the results and the possible sources of error are discussed.

INTRODUCTION

WITH the rapidly increasing use of wireless apparatus it becomes more and more important to know the properties of the materials entering into the construction of such apparatus. In the design of wireless generators the iron losses of the magnetic circuit present one of the limiting features. The eddy current losses can of course be reduced by using thinner laminations, but a limit is soon reached beyond which it does not pay to go for several reasons, chief of which are that as the material becomes thinner the difficulties of rolling are greatly increased and that as the thickness is decreased the hysteresis losses increase. Five-mil silicon steel can be produced without much difficulty and for many applications does not have excessive eddy current losses. In this paper will be presented some iron loss data for five-mil 4 per cent silicon steel for a range of frequencies from 5,000 cycles to 50,000 cycles. The particular material from which these data were obtained had a thickness of 4.9 mils by micrometer, and of 3.9 mils as calculated from the weight and an assumed specific gravity of 7.5. The resistivity as calculated from the weight and the same assumed specific gravity was 62 michroms per cm³.

METHOD OF TEST

After considering various possible methods of test, it was decided to use a double calorimeter method somewhat similar to that used by Nusbaum*, with the additional feature, however, that arrangements were made to determine the induction at which the iron was operating as well as the exciting current. The high frequency supply was obtained from a tungsten arc oscillator devised by Dr. Rentschler of the Westinghouse Lamp Company. Referring to Fig. 1, this oscillator O was supplied with 500 volts direct current from a generator through a lamp bank of tungsten lamps and an Ammeter A_1. Across the arc was connected an oscillating circuit of paper condensers C_1 and a variable inductance L_1. Tapped across a portion of the inductance was a second tuned circuit consisting of a variable condenser C_2, inductance L_2, the thermal ammeter A_2, and the primary winding of the sample to be tested D_1. The object of introducing this second circuit was to damp out any harmonics which might be generated by the oscillator. Inductively coupled with the inductance of the sample circuit was wave meter W. The sample under test consisted of 24 grams of rings 1¾ in. outside diameter by 1¼ in. inside diameter punched from enameled five-mil steel. The sample was insulated with empire cloth tape, wound with a secondary winding of 60 turns of No. 30 magnet wire and a primary winding of 10 turns of No. 18 lamp cord. The secondary winding was connected to a portable electrostatic voltmeter V_2, designed by Dr. Compton of the Westinghouse Lamp Company. This instrument normally gave a deflection of about 10 cm. on a meter distance scale with 30

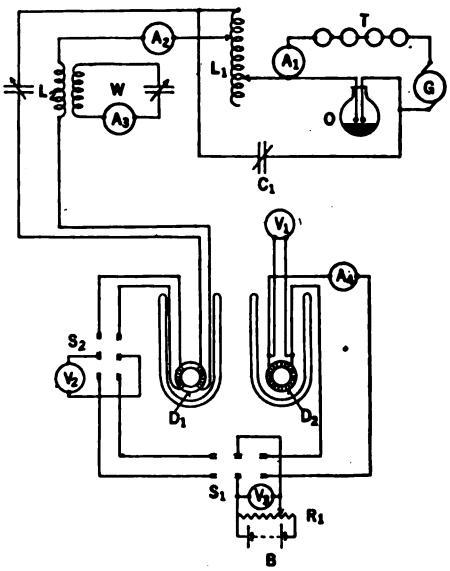

FIG. 1

volts applied. The sensibility was adjustable, however, by changing the level of the instrument. This voltmeter could be connected either to the sample or to a calibrating circuit by means of the switches S_1 and S_2. When connected to the calibrating circuit the voltage was read by means of voltmeter V_3. When switch S_1 was thrown to the right the heater coil D_2 was connected to the battery B. This heater coil was in intimate contact with some five-mil stampings exactly like those of D_1 and of the same weight. The heater coil was made of "advance" wire and was wound around about one-third of the rings. Each of the other thirds was placed outside of the heater coil and the whole insulated with tape in the same way that D_1 was insulated. Thus we had two samples, one of which was heated

*Hysteresis and Eddy Current Losses in Iron at Radio Frequencies, by C. Nusbaum, *Proceedings, Institute of Radio Engineers*, Feb. 1919.

by hysteresis and eddy currents and the other by the I^2R losses in the windings. The ease of escape of heat was about the same for the two samples. The I^2R losses in D_2 were measured by means of the voltmeter V_1 and the ammeter A_4.

The calorimeters, each of which contained one of the samples, consisted of two Dewar flasks about 2 ½ in. inside diameter by 7 in. high. These flasks were made at the same time and were practically identical as shown by cooling curves taken on them. The flasks were filled about two-thirds full of kerosene and each was provided with a stirrer. The equality of the temperatures of the calorimeters was determined by five pairs of copper-advance thermocouples connected differentially to a D'Arsonval galvanometer.

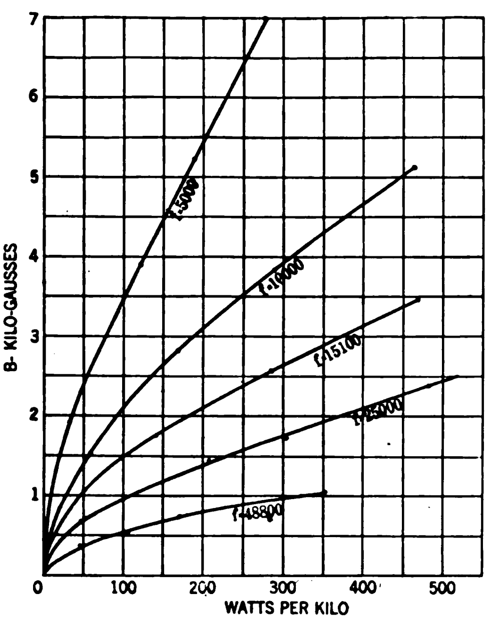

Fig. 2

Procedure

The method of operation was as follows: The oscillator was started by lowering the electrodes into the mercury and then slowly withdrawing them. This was done by tilting the oscillator bulb. The capacity of the sample circuit was adjusted approximately for the frequency desired as determined by calculation. The wave-meter was set for the desired frequency and then the inductance and capacity of the arc circuit adjusted for a maximum reading of the wave-meter. The tap of the inductance L was adjusted until the voltmeter V_2 read a value corresponding to the desired induction for the sample. After these adjustments were made it was found necessary usually to make no further changes except to adjust occasionally for V_2. This might have been done by moving the tap on the inductance but it would usually result in a change of frequency which had to be compensated for. Therefore this voltage adjustment was generally made by raising or lowering the electrodes of the oscillator with respect to the mercury bath by tilting the bulb. A considerable change of voltage could be obtained by this means without materially affecting the frequency. After a run was started the voltage, and therefore the induction, was kept as nearly constant as possible. At the same time current was applied to D_2 and varied until the differential thermocouple galvanometer showed that the two calorimeters were heating at the same rate. V_1 and A_4 were then read and the loss in sample D_1 could be calculated. The thermal ammeter A_2 gave the exciting current and the induction was calculated from the usual formula.

$$B = \frac{E \times 10^8}{4.44 f \times A \times N_2}$$

where E is the voltage, f is the frequency, A is the cross-section of the sample in sq. cm. as determined from the weight and an assumed specific gravity of 7.5 and N_2 is the secondary turns. To obtain the voltage values the electrostatic voltmeter was connected to the battery circuit, R_1 adjusted until the electrostatic instrument read the same as it had on the a-c. circuit and then the voltmeter V_3 read.

In connection with these tests it is interesting to note that in using the various frequencies the average maximum audible frequency of quite a number of observers was about 15,000. One observer in fact was able to adjust the frequency of the apparatus quite accurately at 15,000 due to the fact that his limit of audibility occurred at this point.

In order to eliminate any errors due to possible differences in the two calorimeters, the samples were interchanged at each induction and a second thermal balance obtained.

It was thought that there might be appreciable losses in the primary winding of the sample. In order to determine this point a ring of hard rubber having the same dimensions as the iron sample was wound like D_1, connected in series with the oscillator circuit and placed in one of the flasks. The other flask was left empty. No appreciable heating was produced at 25,000 cycles and two amperes after a period of several minutes. A difference of temperature of one deg. between the two calorimeters corresponded to a deflection of 17 cm. on the galvanometer scale.

In addition to the a-c. tests, ballistic loops were obtained on the sample for $B = 1$, 3 and 5 kilogausses and the hysteresis losses calculated.

Discussion of Results

Table I gives a summary of the test results.

Fig. 2 shows the relation between the induction in kilogausses and the total watt loss in watts per kilogram for 5000, 15,100, 25,000 and 48,800 cycles per second. The inductions are based on net section as calculated from the weight and an assumed specific gravity of 7.5 as mentioned above. If results in gross section are desired, they can be calculated from the space factor

which was about 0.75 for the enameled rings at a pressure of 50 pounds per square inch.

Fig. 3 gives the relation between the induction and the ampere turns per cm. of the exciting current.

Fig. 4 gives the relation between the watts per kilogram and the frequency for various inductions from 0.5 kilogausses to 5 kilogausses.

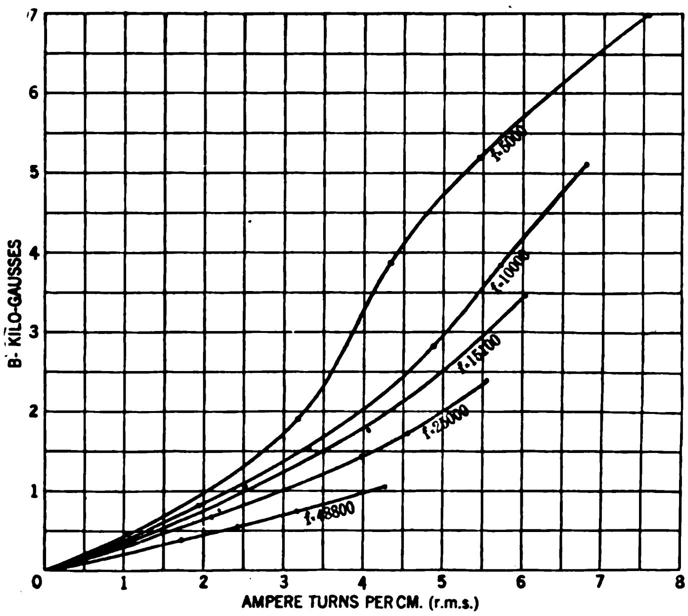

FIG. 3

Fig. 5 gives the relation between the induction and the hysteresis loss in watts per cycle per kilogram as determined from the ballistic loops. This figure also shows magnetization and permeability curves for the material.

Fig. 6 shows the relation between the watts per

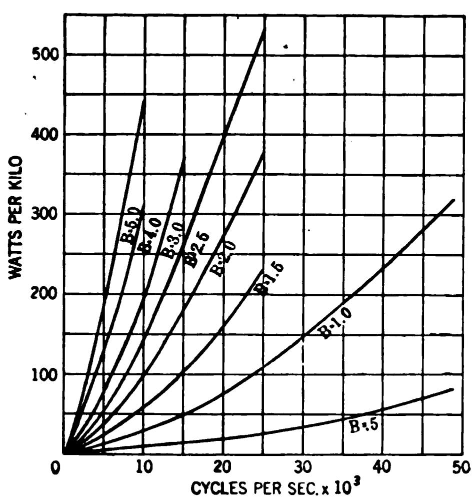

FIG. 4

cycle per kilogram and frequency. The circles on the zero frequency line indicate the ballistic results. It is evident that the relation between the watts per cycle and frequency is not a straight line at the higher inductions, at least as is the case at low frequencies, but has a definite convex tendency upwards. This is undoubtedly due to the skin effect as pointed out by Lloyd and Fisher*, and is explained by them as follows: "The short eddy current paths enclose a smaller flux, while the longest ones enclose the same.

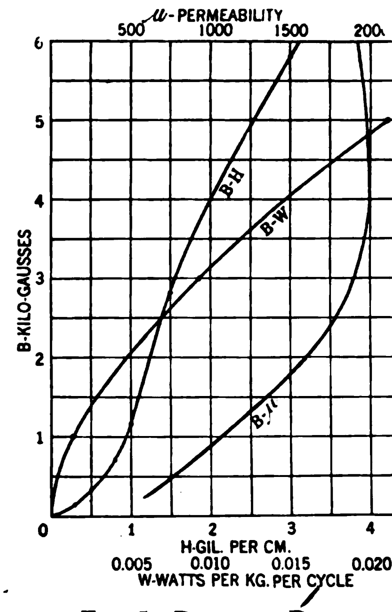

FIG. 5—BALLISTIC DATA

Hence, the average e. m. f. of the eddy current circuits does not increase as fast as the frequency."

Assuming the hysteresis loss as obtained from the

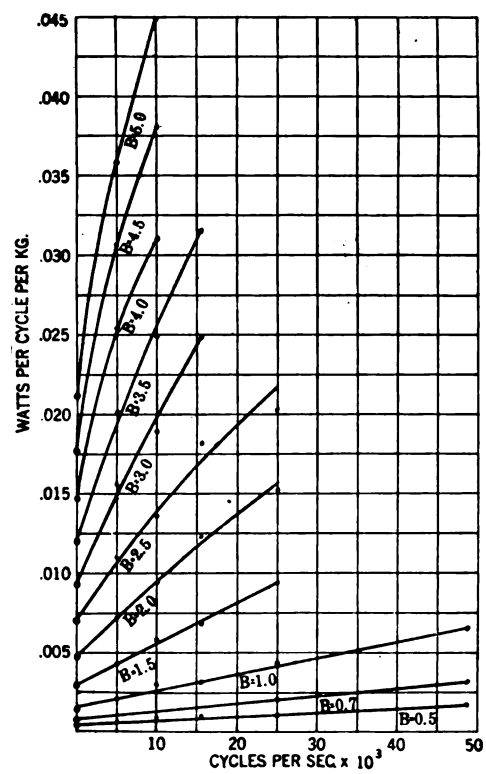

FIG. 6

ballistic tests, the eddy current losses were calculated and the hysteresis and eddy current values were plotted against the induction in kilogausses as shown by

*Bureau of Standards *Bulletin*, Vol. V, No. 4, p. 472-473.

Fig. 7. Next the logarithms of the eddy current losses were plotted against the logarithms of the frequency and the induction as shown by Figs. 8 and 9 respectively. The slopes of the curves are given by the numbers shown just below each line and are the mean

values of the exponents. By this method of analysis it appears that the eddy current losses do not increase as fast as the square of either the induction or the frequency as of course would be expected from the data of Fig. 6. There is another factor however, which should be considered in making such an assumption,

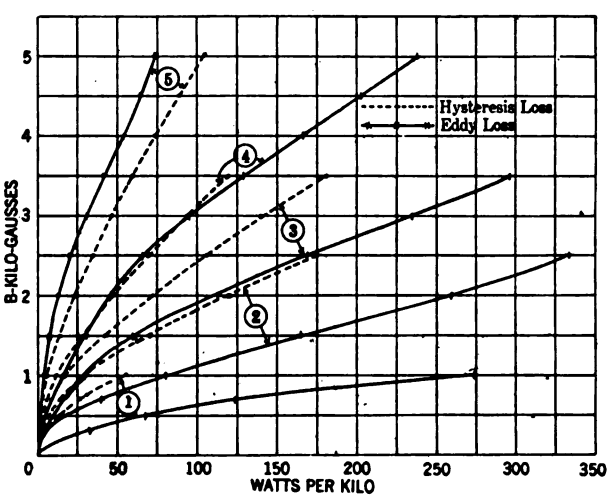

FIG. 7
1—48,800 Cycles. 2—25,000 Cycles. 3—15,100 Cycles. 4—10,000 Cycles. 5—5,000 Cycles.

namely the effect of the non-uniform flux on the hysteresis losses as a result of the skin effect. The actual hysteresis losses are higher than would be the case were the fluxes uniform. Therefore some of the losses which appear as eddy current losses are really hysteresis losses. This effect might be calculated approximately by using Steinmetz' formulas* for skin effect. But it was thought that the accuracy of the present data and the uncertainty as to what permeability values to use would not warrant the time necessary for these calculations as they would be somewhat tedious. Moreover this effect is not large as shown by a calculation of the induction at the centers of the sheet for an average induction of 2000 gausses and a frequency

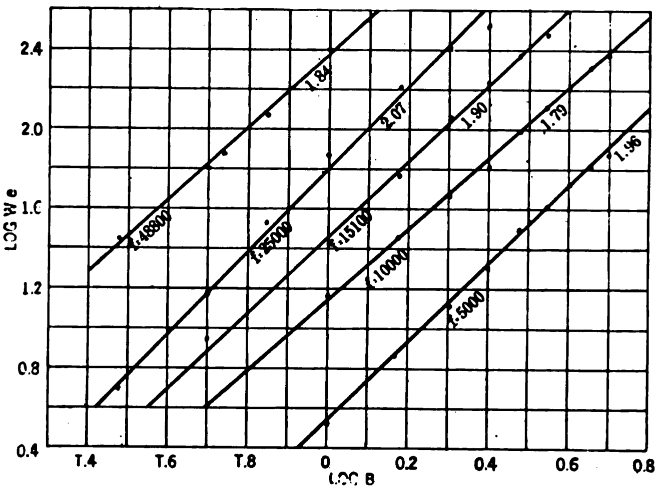

FIG. 8

of 25,000 cycles. As determined from the above mentioned formulas the center induction is 1980 or only 1.0 per cent lower than the mean induction. It seems quite certain that the eddy current losses do not increase as fast as the square of either the frequency or the induction. The reason for this as regards frequency has been pointed out by Lloyd and Fisher, as

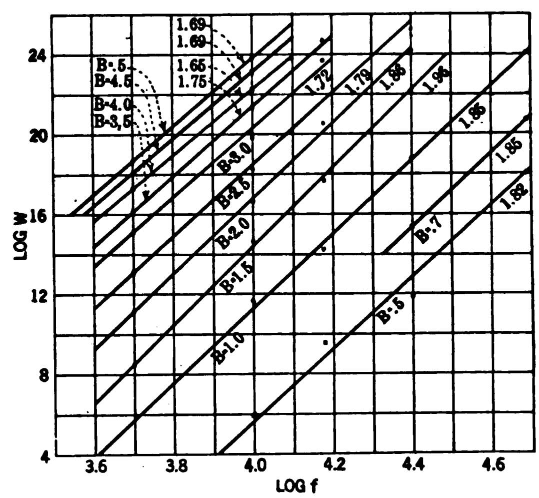

FIG. 9

mentioned above, and a similar reasoning may be applied to the changes with induction, since for the range of induction used in these tests the permeability is increasing with the induction and consequently the skin effect is increasing, thus tending to decrease the eddy current losses from what they would be without this increased skin effect.

*See Transient Electrical Phenomena and Oscillations, p. 359.

Accuracy of Results

The results are probably not reliable to better than 5 per cent. One of the principal sources of error was the fact that at some points the test voltage did not remain very constant in spite of frequent adjustment. This was due partly to variations in the d-c. supply and partly to other causes not fully determined. It was necessary to use a generator for supply as no 500-volt battery was available. Another source of error was due to the changes in the temperature of the calorimeters. In one or two instances these temperatures rose as high as 50 deg. cent. This would of course produce decreased eddy current losses due to the increased resistance of the material. This effect was comparatively small, however, as 4 per cent silicon steel has a fairly low temperature coefficient of resistance. The temperatures were recorded and corrections can be made at a later date if desired. At the lower frequencies the readings of the wave meter were not as sharp as might have been desired due to the fact that the meter was constructed from apparatus that happened to be available and was not as suitable as we might have wished. Another possible cause of error was the fact that while exciting current was probaly very nearly a sine wave the voltage due to the variations in the permeability of the sample with induction undoubtedly contained some harmonics. The inductions were calculated assuming a sine wave of voltage. The errors introduced due to this cause should be small, however, since the samples were not tested at high inductions where such distortions are very appreciable, and also because the instantaneous induction was not uniform.

Conclusions

A method of making high-frequency iron loss tests has been presented which is satisfactory for the range of frequencies used, namely 5000 to 50,000 cycles per second and which without material alterations could be used up to at least a million cycles.

Data are presented showing the iron losses for five-mil silicon steel. An approximate separation of hysteresis and eddy current losses has been made showing the result of skin effect on these losses.

From these data it should be possible to predict more accurately the results obtainable with other gages of material for high-frequency work than was possible with previous obtainable data or formulas.

Electric Power Consumption on the Electrified Rocky Mountain and Missoula Divisions of the Chicago, Milwaukee, & St. Paul Railway

By REINIER BEEUWKES

Electrical Engineer, C. M. & St. P. Railroad, Seattle, Wash.

POWER for the electrical operation of the Chicago, Milwaukee & St. Paul Railway, between Harlowton, Mont. and Avery, Ida., is delivered to the transmission system of the Railway in the form of 100,000-volt, three-phase, 60-cycle current. The power is supplied under two separate contracts, one for the Rocky Mountain Division, extending from Harlowton to Deer Lodge, and the other for the Missoula Division, extending from Deer Lodge to Avery.

The Power Company's 100,000-volt transmission system is shown in Fig. 1, as are also the points of power delivery to the Railway Company and the latter's 100,000-volt transmission system. The Railway transmission line of the Rocky Mountain Division extends from Two Dot substation to the Morel substation, a distance of 184 miles, the former point being 12 miles from Harlowton, the eastern terminus of the Division, and the latter point 17 miles from Deer Lodge, the western terminus. Power is delivered by the Power Company at the Two Dot, Josephine, Piedmont, Janney and Morel substations. The Railway transmission line of the Missoula Division extends from Gold Creek substation, 18½ miles from Deer Lodge, a distance of 180 miles, to the substation at Avery, the western terminus of the Division.

Seven substations on each Division are used to convert the 100,000-volt alternating current of the transmission line to the 3000-volt direct current used for traction purposes. Each motor-generator consists of two 1500-volt direct-current generators connected in series and driven by a 2300-volt synchronous motor supplied from the substation high-tension buses through a three-phase, 100,000/2300-volt transformer and is guaranteed for a maximum five-minute overload of 200 per cent. The rated capacities of these stations are as follows:

Presented at the Pacific Coast Convention, A. I. E. E., Portland Ore., July 21-23, 1920

Substations	Transformers	Motor-generators
Rocky Mountain Division

the trolley in front of each substation separating the trolley system west of the substation from that east of the substation, that is, portions east and west of the substations are fed, respectively, through separate feeder breakers. There is also an insulated air gap at the beginning and end of every passing track, so that by means of a section switch installed in the feeder at the gap the district between any two gaps may be isolated in case of trouble so as to permit operation up to the location of the open switches.

The return circuit consists of the 90-lb. running rails and, in general, of a No. 0000 B. & S. copper supplementary negative wire which is run along the

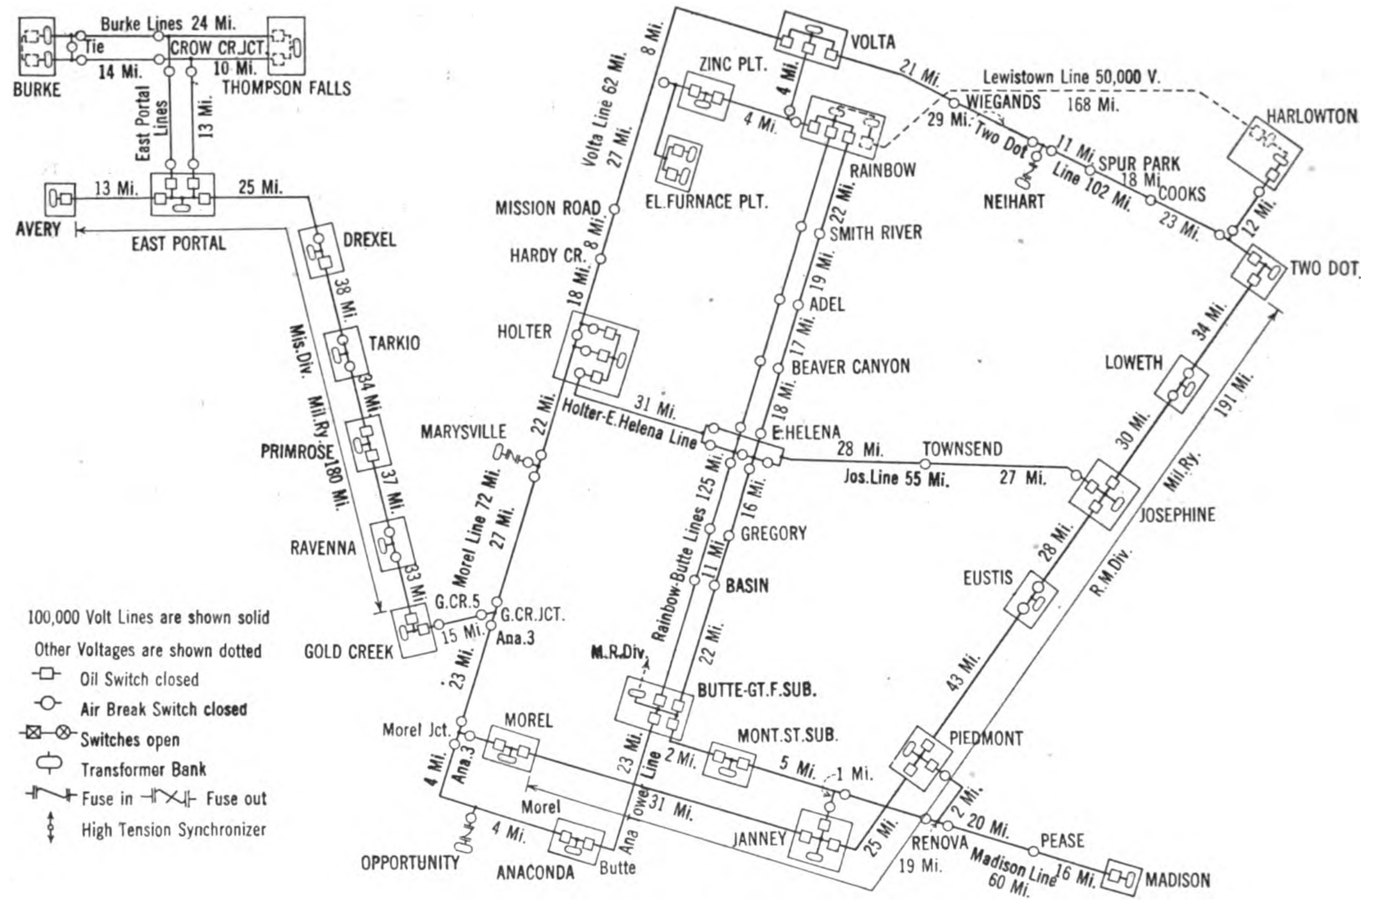

FIG. 1—THE MONTANA POWER COMPANY 100,000-VOLT SYSTEM

The Railway Company's high-tension line, arrangement of apparatus in the substations and the general layout of the 3000-volt distribution or trolley system are shown diagramatically in Figs. 2 and 3.

The contact wires of the trolley system consist for the main line of two No. 0000 B. & S. grooved trolley wires flexibly supported side by side from a ½-in. steel catenary and tapped at intervals of about every thousand feet to a feeder or feeders which connect to the adjacent substation buses through switches and automatic circuit breakers. Over passing, industrial and similar tracks only a single No. 0000 copper trolley wire is used. There is an insulated air gap in trolley poles and connected to the track at intervals averaging about 8000 ft. through each alternate signal system reactance bond. This supplementary negative, however, is intended more as a safety measure to bridge open rail bonds than to increase the return circuit conductivity. However, on various feeder cut-offs on the mountain grades, where the conductivity of the positive circuit closely approaches that of the return circuit, one of the two feeders on the cut-off is in parallel with the running rails and is provided for the purpose of increasing the return circuit conductivity.

The terms of the power contracts are similar and

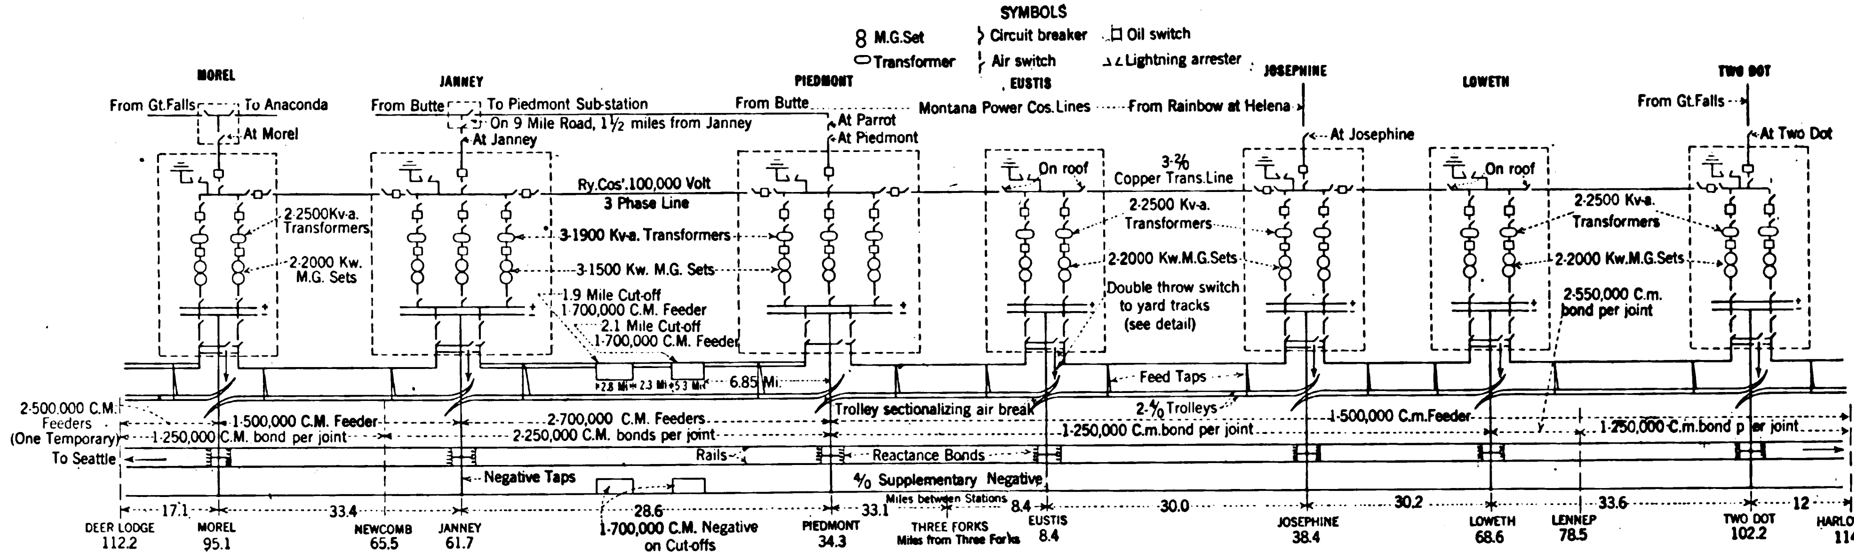

Fig. 2—Transmission and Distribution System—Harlowton to Deer Lodge

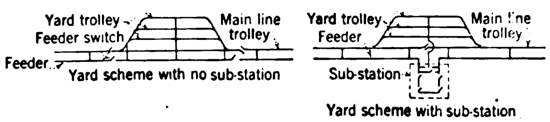

Yard Schemes

Feeder and trolley sectionalized at all substations and Railway stations.
One No. 0000 feeder tap to each trolley every 1000 feet.
Reactance bonds 5000 to 6000 feet apart.
Negative-tapped to middle point of every second reactance bond.
Side track rails are bonded in series with the supplementary negative.

One rail bonded with one 250,000 cir. mil bond per joint in yards.
Signal: Two No. 4 B. & S. copper wires carried on trolley poles. Fed both directions from substations, 4400 volts a-c.
Power limiting: Two No. 8 B. & S. copper wires carried on trolley poles—Morel to Two Dot—1200 volts d-c.

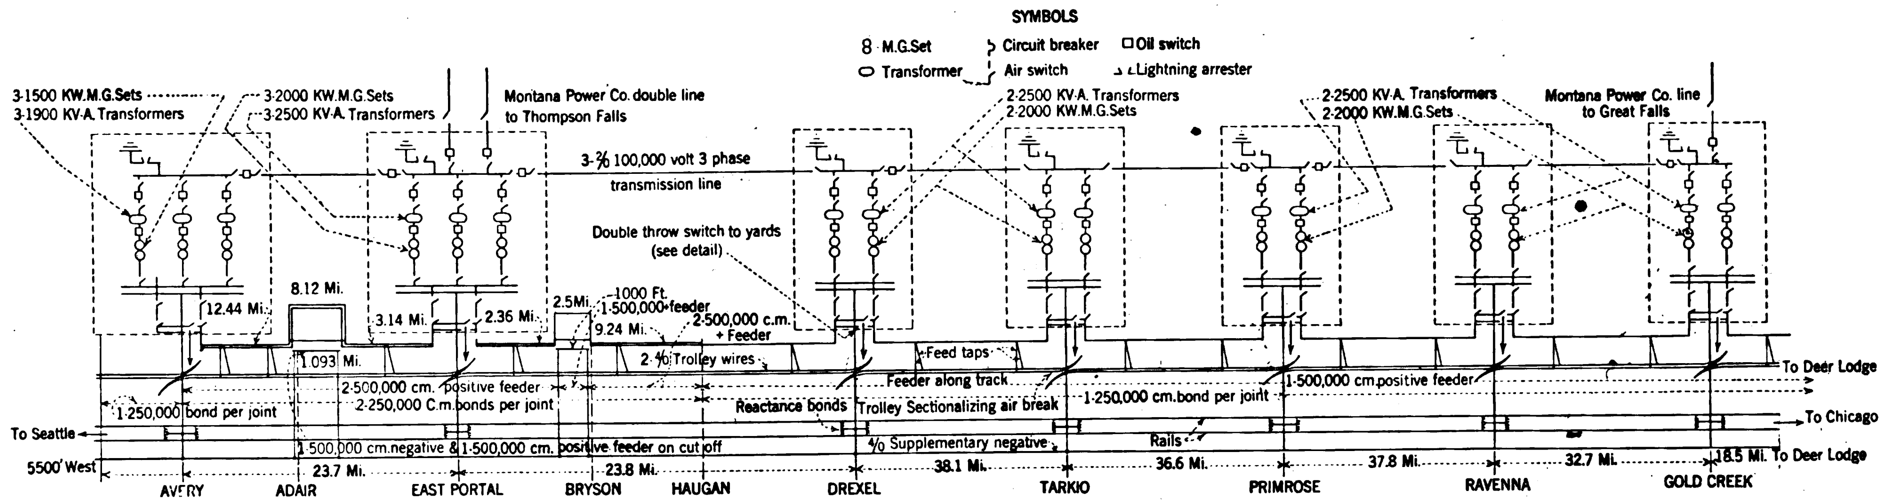

Fig. 3—Transmission and Distribution System—Deer Lodge to Avery

Feeder and trolley sectionalized at all substations and Railway stations.
One No. 0000 feeder tap to each trolley every 1000 feet.
Reactance bonds 5000 to 6000 feet apart.
Negative tapped to middle point of every second reactance bond.
Side track rails are bonded in series with the supplementary negative.
One rail bonded with one 250,000 cir. mil bond per joint in yards.

Trolley feed taps are disconnected for a distance of one mile each side of each substation where there is a single feeder and two miles where there is double feeder, except at Ravenna where the tunnel entrance East, and at East Portal where the tunnel entrance West will limit the distance.

Yard switch at substation left open. Yard trolley at substation connected to main line trolley of east end of yards.

each provides for a minimum payment on basis of a 60 per cent load factor. Where the load factor exceeds 60 per cent, payment is made on basis of the actual kw-hr. consumed, the rate being 5.36 mils per kw-hr. The demand is controlled for each division by means of a so-called Power Indicating and Limiting system, which was put into operation on the Rocky Mountain Division early in the year 1918 and on the Missoula Division a few months ago. Briefly, this system, which was described in detail in the April, 1920 issue of the *General Electric Review*, is so arranged as to indicate and record at the dispatcher's office at Deer Lodge the total kilowatts or demand being latter matter, except as regards passenger trains and certain time freights, being to a considerable extent in the hands of the train dispatchers. The slowing up of the train speeds of course results in increased train and enginemen's expense and increased time in getting freight over the road, and a proper balance must be struck between this increased expense and the saving in power cost, determining upon the limit setting accordingly. The following tabulation will give an idea of the percentage of time the limiting action takes place with average kw. load and settings as indicated, this percentage being based on the number of hours the limiting system was actually in service.

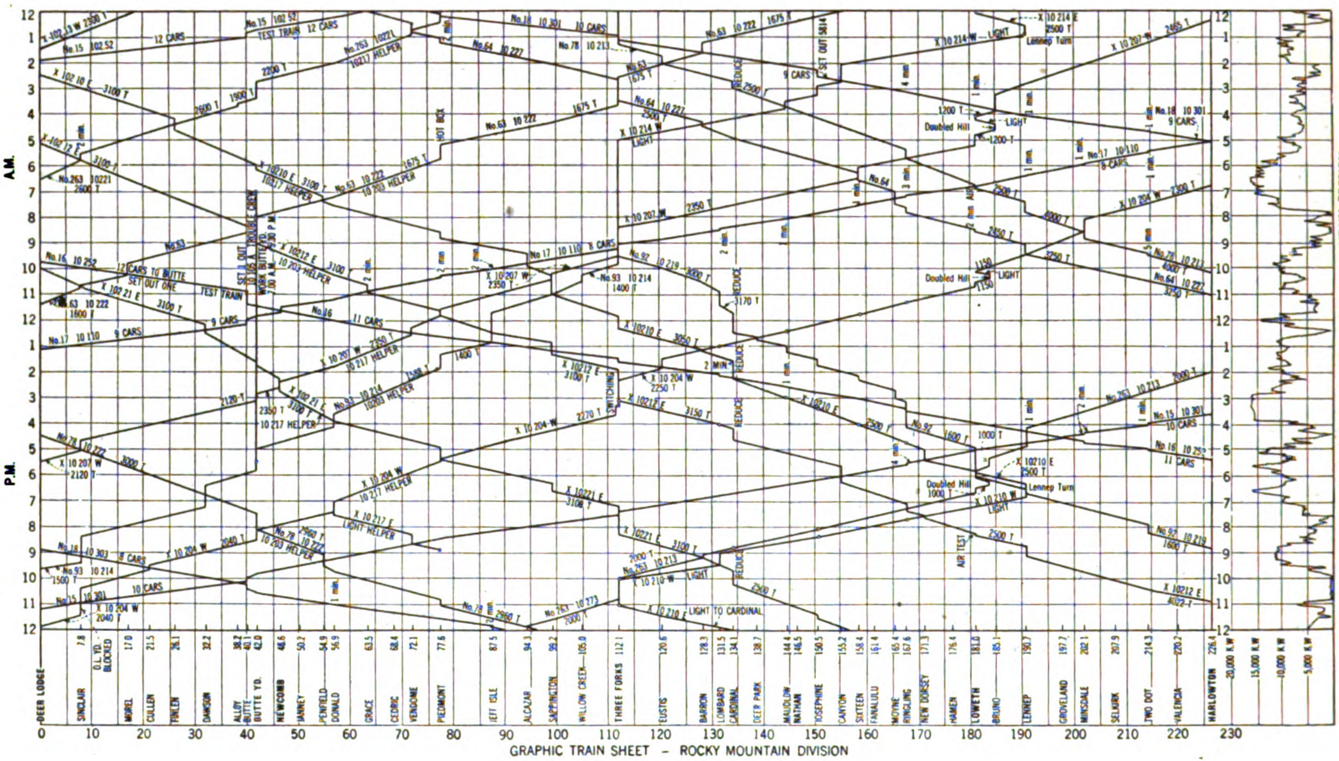

FIG. 4

supplied in any instant by the Power Company to the Railway Company, and to prevent the maximum demand from exceeding a certain amount as determined by the "demand setting made by the dispatcher," this limiting action being secured by lowering of the substation d-c. voltage and therefore of the train speeds.

The effect of this limiting action is clearly indicated in Fig. 4, which shows a graphic time table of train movements on the Rocky Mountain Division for February 19, 1920 and corresponding load curve traced by tapalog meter of the Power Indicating and Limiting system with the load limit set at 16,000 kw.

The percentage of time when the limiting action will take place will, for a given amount of business, depend on the demand setting and on the possibilities of spacing the trains so that as few as possible will at one time be operating on the heavier grades; the

Month	Limit setting	Avg. monthly kw. actual	Per cent time limiting actual takes place
July, 1918	12,000	8,020	13.0
Aug., "	12,000	7,820	15.5

Mar., "	16,000	8,680	2.20
Apr., "	16,000	8,620	1.90

In arriving at the amounts chargeable for power against the different respective classes of train service, the total kw-hr. to be paid for, that is, the actual kw-hr., or same increased, if necessary, to correspond to a minimum 60 per cent load factor, is taken and from it

is deducted the kw-hr. metered against substation lighting, auxiliary power, signal system supply, etc. amounting to about 1 per cent. The remaining kw-hr. is then split against the different classes of train service, freight, passenger and non-revenue, in proportion to the total net kw-hr. readings obtained for these respective services from wattmeters installed in the locomotives. These readings are taken by the engine crew on entering and leaving the engine on a form provided for the purpose, and a record of the power consumption of each train is thus obtained. The readings are referred to as "net" readings, as they represent motored energy less regenerated energy.

The ratio of the total net locomotive wattmeter readings, all services, to the total actual kw-hr. input to system chargeable to locomotives for the various months of 1919 and for the whole year is given below:

	ROCKY MOUNTAIN DIV.			MISSOULA DIV.

As there are no wattmeters installed in the direct-current side of the substations, a ratio for net substation output to system input or to locomotive input is not obtainable. There are, however, wattmeters in the circuits of the individual motor-generator sets, and the following table considered in connection with Profile, Fig. 5, will be of interest in showing the manner in which the energy is distributed among the respective substations, average kw. being used for convenience instead of total kw-hr., and the whole of the year 1919 being taken.

ROCKY MOUNTAIN DIVISION			MISSOULA DIVISION

*Total Kw-Hr.—Hr. in year: 8856 hr. being taken, as four days in December are included.

†Total Kw-Hr.—Total running hr. of motor-generators.

The figures below show for the year 1919 the net kilowatt-hours per thousand gross ton miles for freight revenue service and passenger service, respectively, and corresponding cost of these kilowatt-hours at tho high-tension bus or point of delivery of the power te the railway system. The lesser consumption of energy during the summer months as compared with the winter months will be noted. The figures for the passenger service are approximate, as the ton mile data are based on the assumption of an average weight per car, no record of the particular cars handled in all the separate trains being available:

Month	Thousands gross ton miles trailing	Net kw-hr. per thousand gross ton miles: Trailing, At high tension bus	Trailing, At locomotive	Train, At high tension bus	Train, At locomotive	load factor	Cost kw-hr. per thous. trailing gross ton mi., cts.

The cost of maintaining and operating the transmission lines, substations, and trolley system, for the year 1919 is given below and a final figure thus arrived at showing the approximate total operating costs involved in the delivery of the electric energy to the locomotives.

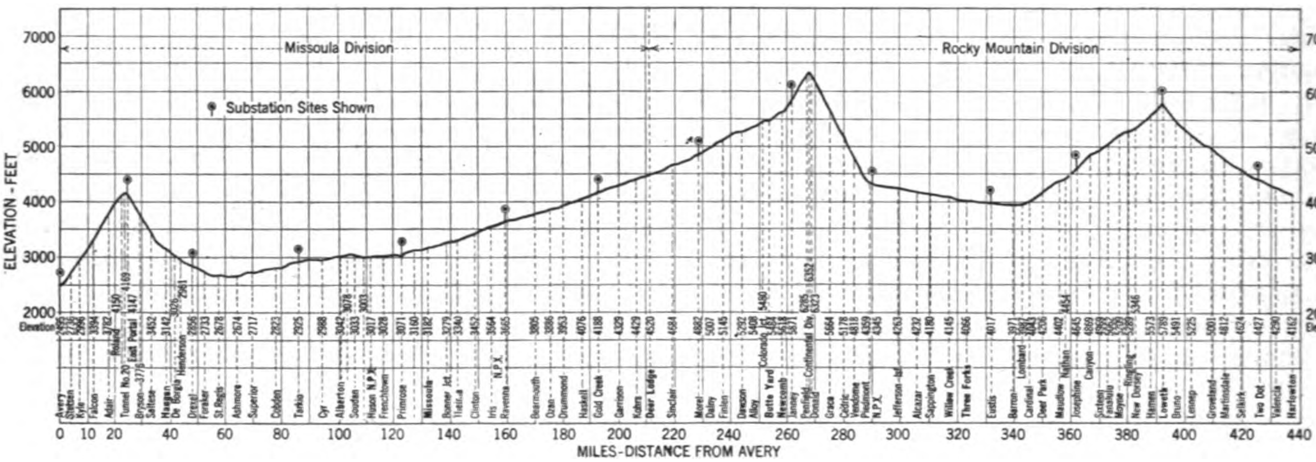

Fig. 5—Profile—C., M. & St. P. Ry.—Missoula and Rocky Mountain Divisions

Account	Total All Services	Per Unit
255. Power Substation Bldgs...	$8,487	$606.00 per Bldg.
257. Power Transmission System..................	1,773	4.87 " mi.
259. Power Distribution System..................	78,461	179.00 " route mi.
261. Power Line Poles & Fixtures.................	24,299	55.50 " " "
306. Power Substation Apparatus.................	40,224	2870.00 " station
383. } Train and Yard Power 935. } Produced.............	102,152	7300.00 " "
Total...................	$255,396	

1. Cost per Thousands Gross Ton Miles trailing freight as actually distributed in accounts	28.8c
2. Cost per Thousands Gross Ton Miles train freight as actually distributed in accounts..	24.9c
3. Cost per Thousands Gross Ton Miles trailing freight on basis distribution in proportion to freight kw-hr......................	30.2c
4. Cost per Thousands Gross Ton Miles train freight on basis distribution in proportion to freight kw-hr......................	26.2c
5. Cost per actual kw-hr. delivered to locomotives............	1.1c

The above unit figures include the cost of power.

The installation being comparatively new it might naturally be assumed without consideration of other facts that the figures for the maintenance are considerably lower than those which will eventually obtain, but it should also be borne in mind that the maintenance and operating costs given will, except for power, remain more or less constant as far as any consideration of their being affected by the business handled is concerned, so that the cost per thousand ton miles would be correspondingly reduced as business is increased. It is also expected that considerable improvement will be effected in maintenance methods which would again tend to reduce costs. The figures are therefore given merely to show the results which are at present being obtained.

AMERICAN PAPER NOW USED ENTIRELY BY TELEPHONE MANUFACTURERS

The newspaper trade is not the only industry which is being affected by the shortage of paper. Few users of the telephone realize that one of the big elements in the makeup of the underground cable, the magneto and several of the other important adjuncts to the lines of communication is paper. In fact, it is the big factor for insulating purposes. Several layers of it are used beneath the leaden sheath the average human sees when telephone cables are being laid in the streets of his vicinity. The shortage condition of the grade of paper which has always been used has become so acute that several experts of the Western Electric Company are devoting all their efforts to developing some type of substitute.

Manila pulp paper has always been the big favorite among telephone cable manufacturers. Recently wood pulp has been used because of the shortage of the former but it still lacks several of the finer qualities of the imported grades. Elasticity and a non-porous condition are absolutely necessary.

Prior to the war large quantities of all-linen paper made in Europe were used in certain processes in making condensers. None of the American manufacturers cared to handle it as it required so much attention and had such a limited distribution. However, three companies have now taken over the task in this country and although cotton is used to a large extent their output is every bit as good as that of their foreign competitors.

AERIAL MAPPING

The Army Air Service is now cooperating with map-making companies in making detailed maps of the immediate vicinity of Washington. This is another step in proving the reliability and utility of maps made from the air for commercial work. A number of very successful and complete air maps have been made in the past and following the success of each venture larger projects are undertaken in map-making from the air. Important camera developments are now having the attention of the Air Service for this work, together with other special airship equipment.

Some cooperation has been given to the Coast & Geodetic Survey and it is contemplated that aerial photography will eventually be a considerable help in developing the complete topographic map of the States.

The Electric Dynamometer Test of the Pierce Arrow Engine

By KARR PARKER
Engineering Manager, McCarthy Bros. & Ford

THE electric dynamometer is now generally recognized as the standard equipment for testing automobile engines. Dynamometers are used not only to measure the power of the engine in the final test but also are employed as tools in the production of the engine. Engines when first assembled are "run in" on block test dynamometers until the bearings, etc., are worked in. In this process the dynamometer runs as a motor delivering power to the engine. When the friction load on the engine has been reduced to the proper value as determined by a meter on the dynamometer control panel, the engine is fired and drives the dynamometer as a generator returning current to an absorption resistance or to the plant system, thus providing a load for the engine. The engine is tested for power one with this artificial load.

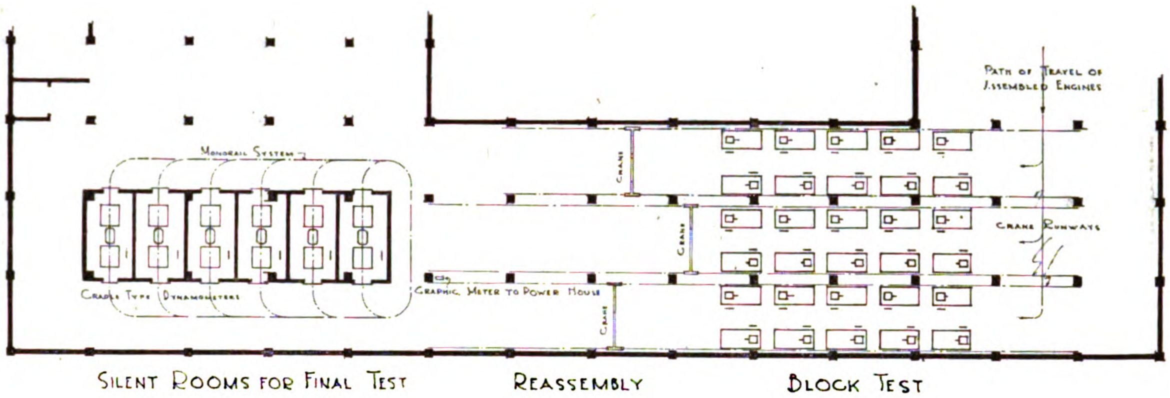

FIG. 1

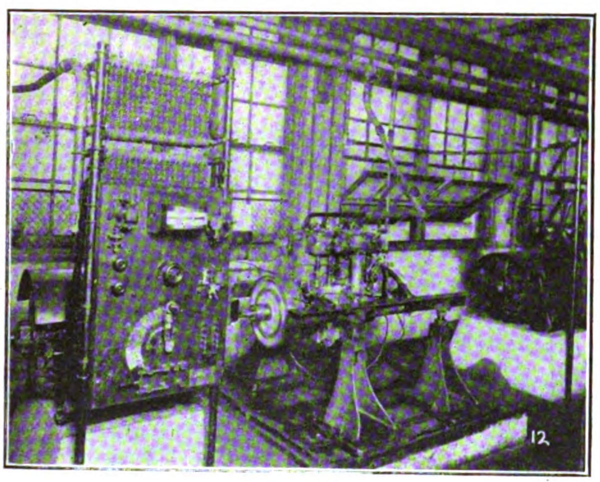

FIG. 2

A complete dynamometer testing equipment has recently been installed at the plant of the Pierce Arrow Motor Car Company. The engine test here is exceptionally rigid and the installation is considered to be one of the best in existence.

The old method of testing this engine consisted in "running in" the engine by belting to a line shaft. This process required a number of hours and was a fixed period for each engine. The engine was then transferred to a test room and coupled to a fan. It was then fired and run at various speeds over a fixed schedule for some days. The fan provided the artificial load and the power developed was calculated from the fan characteristics.

In designing the electric dynamometer installation careful attention was paid to locating the equipment so that the engine would not only receive proper test but would also pass from production to test directly without delay. The testing floor plan is shown in Fig. 1. Engines when finished are transferred to the block test stand by means of an electric hoist and are "run in" until their friction load drops to a predetermined value. The dynamometer runs as a motor at this stage of the process taking current from the test room bus which is supplied by other dynamometers which are generating. A block test unit in operation is shown in Fig. 2. The meter on the panel reads directly in horse power and kw., the efficiency of the dynamometer having been taken account of in the calibration of the instrument. The engine is then fired and run for several hours at various speeds and powers as called for by the test schedule.

The power generated during the process is 250-volt direct current. The surplus power is transmitted to

the power house; changed into three-phase, 25-cycle, 440-volt alternating current by a 550-kw. synchronous converter and is then used to drive various a-c. motors in the factory. The synchronous converter switchboard is shown in Fig. 3. A surplus of several hundred horse power is available from the dynamometer test

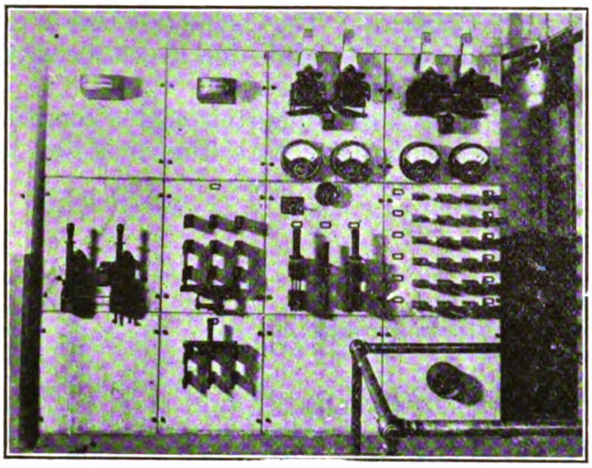

FIG. 3

at all times. Testing is arranged on a uniform schedule which gives a certain number of engines firing at all times. A view of the block test section of the testing room, showing overhead cranes, is shown in Fig. 4. A total of 30 units is installed here.

If an engine gives trouble in the block test or fails to come up to power it is immediately rejected and

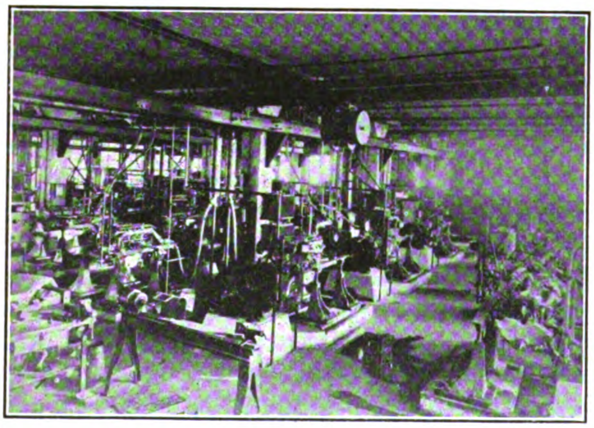

FIG. 4

sent back to be taken down. After an engine passes the block test it is taken down for careful examination, reassembled and delivered by means of an electric monorail hoist to the final test. Fig. 5 shows a passenger car engine being delivered to one of the "silent rooms" for final test.

The final test is conducted on a cradle type dynamometer of 150-h. p. capacity capable of running at speeds up to 3500 rev. per min. This machine consists of a special direct-current interpole generator mounted on ball bearing pedestals so that the entire frame of the machine is free to turn. When the machine is operating the field tends to turn with the armature but is restrained by means of a scale and lever

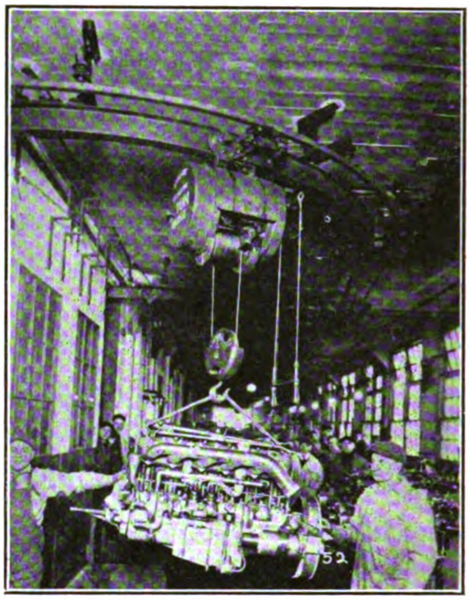

FIG. 5

mechanism with limit stops. The torque exerted on the field by the revolving armature is read on this scale; the speed is read from an electric tachometer.

The power is,

$$\text{h. p.} = \frac{2\,\pi.\ \text{rev. per min. . lb. pull . torque arm}}{33{,}000}$$

This is worked out on a chart so that the tester can read h. p. directly from the line on the chart without calculation.

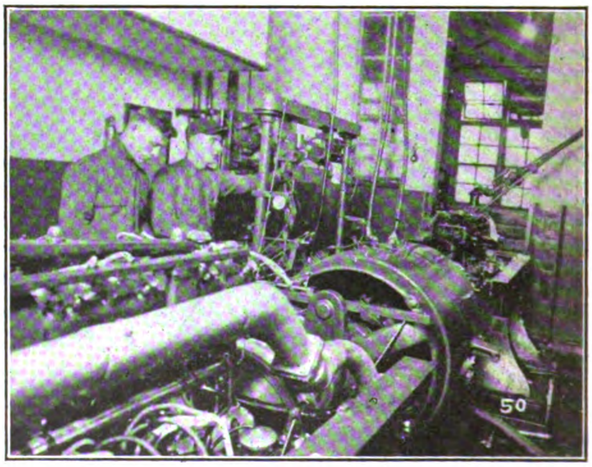

FIG. 6

The cradle dynamometer is arranged with a double extended shaft with heavy bed plate and adjustable engine supports on each end. Considerable time is required to set up an engine, attach flexible coupling,

water, gasoline and oil piping, and line up with the dynamometer shaft. With this double ended arrangement an engine can be set up on one end while another engine is being tested, thus reducing the idle time of the dynamometer to a minimum. A passenger engine undergoing final test is shown in Fig. 6.

The final test is conducted in sound-proof rooms, each engine being tested in a room by itself so as to detect knocks and noises which indicate engine trouble. A power curve is taken of each engine.

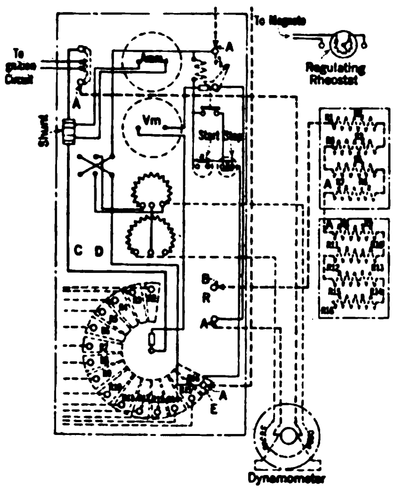

FIG. 7—WIRING DIAGRAM OF DYNAMOMETER PANEL

The control system on the cradle dynamometers is shown in Fig. 7. A wide range of speed in several thousand steps from 0—3500 rev. per min. can be obtained by combined armature and field control. An automatic circuit breaker provides overload protection. This breaker has an auxiliary switch which cuts out the engine ignition when the breaker opens thus preventing the engine from running away. Automatic control is used with control buttons located at tester's desk where the engine controls are also placed. Dynamometer fields are separately excited and when the dynamometer is generating above bus voltage of 250 volts at high speeds, the load is absorbed on a grid resistance.

The principal advantages which the electric dynamometer test has shown over the old method in this plant may be summarized as follows:

a. A more accurate and thorough test.

b. The ability to measure each engine individually and to give a motor individual treatment.

c. Shortening the average test period.

d. Motor rejections on road tests practically eliminated.

e. Increased production because of better arrangement of test room.

f. Defective motors promptly detected.

g. Several hundred horse power formerly wasted is now utilized.

TESTS ON FADING RADIO SIGNALS

Simultaneous nightly tests by 50 radio stations on the fading of radio signals were conducted from June 1 to July 17. The tests covered the northeast quarter of the United States. One thousand records of signal intensity variation have been secured.

A conference has been held to review the results and plan further work by representatives of the Radio Laboratory of the Bureau of Standards, the Naval Air Service, the Department of Terrestrial Magnetism of Carnegie Institution of Washington, and the American Radio Relay League. The data secured are being analyzed. A revised arrangement of cooperating stations will be utilized in future tests, which it is planned to run in October, January and April respectively.

Like the former tests these will be run between 10 and 11 p. m., eastern standard time, and at a wave length of 250 meters. It is intended also to make noonday and sunset runs.

The operation of the first test series has been satisfactory, 60 per cent of the possible number of reports having been secured over an average transmission distance of 350 miles. This is an excellent record for an undertaking in which the observing work is done on a voluntary basis. The power input at the transmitter did not exceed one kilowatt in any case.

One of the six transmitters was a 500-cycle quenched-gap set, two were 60-cycle non-synchronous rotary gap sets, and two were continuous-wave sets using electron tubes. All receiving stations were equipped with regenerative electron-tube receiving sets of the tuned plate-circuit type.

AN ELECTRON TUBE TRANSMITTER OF COMPLETELY MODULATED WAVES

The Bureau of Standards has recently issued Scientific Paper No. 381 on the above subject.

In order to utilize a radio-frequency wave train of given power most effectively in a non-oscillating receiving system it must be completely modulated, at some suitable audio frequency. A convenient way of accomplishing this modulation, when an electron tube generator is used, is by supplying the plate circuit of the tube or tubes with an audio-frequency alternating e. m. f. An alternator may be used with suitable transformers to supply both the filament and plate circuits. A self-contained transmitting set of this type has been designed and built at the Bureau of Standards. A description of the set, with illustration and diagrams is given. Over-all efficiency as high as 35 per cent is obtained with the set. Transmission and reception tests are described, in which the waves were received by heterodyne methods and also with a crystal detector.

This paper is now ready for distribution and anyone interested can obtain a copy by addressing the Bureau of Standards.

External Field Produced by a Cylindrical Electromagnet

BY CARY T. HUTCHINSON
Consulting Engineer, New York, N. Y.
AND
HAROLD PENDER
University of Pennsylvania, Philadelphia

IN some investigations by the authors during the Great War occasion arose to solve the following problems:

PROBLEM A. Given the dimensions and permeability of a straight cylindrical iron core, how many ampere-turns, uniformly distributed over the length of the core, are required to produce a given magnetizing force (magnetic field intensity) at a point on the axis of the core at a distance from its center large in comparison with its length?

Answer:

$$\text{Ampere-turns} = \frac{6.37\,x^3}{d^2}\left(\frac{1}{\mu} + \frac{K}{\rho^2}\right)H$$

where

H = magnetizing force, in gilberts per cm.,
x = distance of point from center of core, in centimeters,
d = diameter of core, in centimeters,
μ = average permeability of core, in c. g. s. electromagnetic units,
ρ = ratio of the length of the core to its diameter,
K = a factor whose value depends upon the value of ρ, and given by the lower curve in Fig. 6.

PROBLEM B. When the core is excited by means of an alternating current, how many volt-amperes are required to produce a given maximum magnetizing force at a point on the axis of the core at a distance from its center large in comparison with its length?

Answer:

$$\text{Volt-amperes} = \frac{\pi^2 f\,x^6}{V}\left(\frac{1}{\mu} + \frac{K}{\rho^2}\right)H^2 \times 10^{-7}$$

where

f = frequency of current, in cycles per second,
V = volume of core in cubic centimeters

and other symbols as in Problem A.

PROBLEM C. What disposition of the winding on the core will require the least number of volt-amperes for a given magnetizing force at the given point; *i. e.*, should the winding be uniform, concentrated at the center of the core, or concentrated at the ends?

Answer: For maximum external field per volt-ampere of excitation, the winding should cover the entire length of core and be uniformly distributed.

PROBLEM D. For a given number of volt-amperes, and given weight of core, by how much will the magnetizing force at a given point on its axis (extended) be increased by using a tapered core (*e. g.*, cone-shaped ends) instead of a core of uniform cross-section?

Answer: For the same volume of core and same number of ampere-turns, a tapered core will give a slightly greater magnetizing force, but the difference is so small that it is doubtful whether the slight gain from a tapered core would justify the extra cost.

The method of arriving at the above conclusions is given in detail in the following paragraphs.

MAGNETIZING FORCE AT EXTERNAL POINT ON AXIS OF CORE EXPRESSED IN TERMS OF THE AVERAGE FLUX IN THE CORE

The strength of the magnetic pole at an area $d\,S$ of the surface of a piece of iron or other magnetic substance (the surrounding medium being non-magnetic) is

$$d\,m = \frac{d\,\phi}{4\,\pi}(1 - 1/\mu) \tag{1}$$

where $d\,\phi$ is the magnetic flux (number of lines of magnetic force) through this area and μ is the permeability of the iron just inside this surface.[1] In this formula all quantities are in c. g. s. electromagnetic units. When the permeability is 100 or more c. g. s. electromagnetic units, equation (1) becomes, with an error of less than 1 per cent,

$$d\,m = \frac{d\,\phi}{4\,\pi} \tag{1 a}$$

The magnetizing force (or magnetic field intensity) at any point P at a distance x from a pole of strength $d\,m$, due directly to this pole, is, in c. g. s. electromagnetic units,

$$d\,H = \frac{d\,m}{x^2} \tag{2}$$

irrespective of the nature of the medium in which the point P is located. Hence, at a point P at a distance x from an area $d\,S$ in the surface of a magnet, through which area passes $d\,\phi$ lines of force, the magnetic pole at this area produces a magnetizing force

$$d\,H = \frac{d\,\phi}{4\,\pi\,x^2} \tag{3}$$

The magnetic poles on a straight iron core, even

1. See Pender, Harold, *Electricity and Magnetism for Engineers*, (1918,) p. 241.

though it be relatively long compared with its diameter, are in general not confined to its end surfaces, but are distributed over its lateral walls as well. That is, an appreciable proportion of the total flux through the core passes out through its lateral walls, so that the flux through successive cross-sections of the core diminishes with the distance of the given cross-section from the center of the core, as shown in Fig. 1.

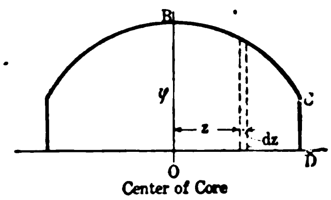

FIG. 1

Consider the special case (Fig. 2) of a point P which is on the axis of a straight core of length l, and at such a distance x from its center that $(l/x)^2$ is negligible in comparison with unity. Consider an elementary length $d\,z$ of this core at a distance z from its center and in its north pole half. Let $d\,\phi$ be the flux which passes through the lateral walls of this elementary

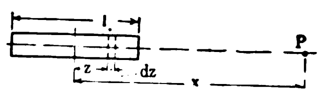

FIG. 2

length, *viz.*, $d\,\phi$ is the difference between the flux through the cross-section which is at a distance z from the center of the core and the flux through the cross-section at the distance $(z + d\,z)$ from the center.

Then the magnetizing force at P due to the pole on the lateral walls of the length $d\,z$ is

$$d\,H_n = \frac{d\,\phi}{4\,\pi\,(x-z)^2} \tag{4}$$

Similarly, the magnetizing force at P due to the pole on the lateral walls of an elementary length $d\,z$ at a distance z from the center of the magnet, but in its south pole half, is

$$d\,H_s = -\frac{d\,\phi}{4\,\pi\,(x+z)^2}$$

The resultant magnetizing force at P d to these two elementary lengths is then

$$d\,H = \frac{d\,\phi}{4\,\pi}\left[\frac{1}{(x-z)^2} - \frac{1}{(x+z)^2}\right]$$

$$= \frac{z\,d\,\phi}{\pi\,a^3\left[1-\left(\frac{z}{x}\right)^2\right]^2} \tag{5}$$

When a is so large in comparison with z that $\left(\frac{z}{x}\right)^2$ may be neglected in comparison with unity, as is here assumed, this equation becomes

$$d\,H = \frac{z\,d\,\phi}{\pi\,x^3} \tag{5a}$$

The resultant magnetizing force at P due to the magnetic poles on the entire lateral surface of the core is the integral of this expression between the limits $z = 0$ and $z = l/2$. Hence the resultant magnetizing force at P due to the poles on the entire surface of the core is (see Fig. 1)

$$H = \frac{1}{\pi\,x^3} \times (\text{Area } B\,C\,D\,O)$$

The area $B\,C\,D\,O$, however, is equal to the *average* value of the flux through the core (*i. e.*, the average ordinate of the curve $B\,C$) multiplied by one-half the length of the core. Let this average flux be designated ϕ_a. Then the resultant magnetizing force at P is

$$H = \frac{l\,\phi_a}{2\,\pi\,x^3} \text{ gilberts per cm.} \tag{6}$$

where l is the length of the core, in centimeters, x is the distance of the point P from the center of the core, in centimeters; and ϕ_a is the average flux through the core in maxwells.[2]

Hence the magnetizing force produced at any point on the axis of a straight core at a distance from its center great in comparison with its length is (1) directly proportional to the length of the core, (2) directly proportional to the *average* flux through the core, and (3) inversely proportional to the cube of the distance of the point from the center of the core.

In order to check this formula, and others which will be given subsequently, an iron core solenoid was constructed as follows: The core was a bundle of 272 straight, soft iron wires. The cross-section of the bundle was practically circular. The length of the core was 102 centimeters. The total cross-section of iron in the core was 8.45 square centimeters. As the "effective" diameter of the core is taken the diameter of a circle of this same radius, *viz.*,

$$d = \sqrt{\frac{4 \times 8.45}{\pi}} = 3.28 \text{ centimeters.}$$

The core was uniformly wound throughout its length (except the last two centimeters at each end) with a total of 735 turns of insulated copper wire (No. 12 A. W. G.). This winding was divided into 21 coils, with both terminals of each coil brought out to binding posts. With this arrangement the core could be excited with any number of coils in series, or different currents could be sent through the several coils in order to make any desired distribution of the ampere-turns.

2. The gilbert per centimeter is the same as the c. g. s. electromagnetic unit of magnetic field intensity.

The flux through the successive cross-sections of the core was measured by means of an exploring coil and ballistic galvanometer. The magnetizing force at a point on the axis of the core, 315 centimeters from its center, was measured by means of a magnetometer.

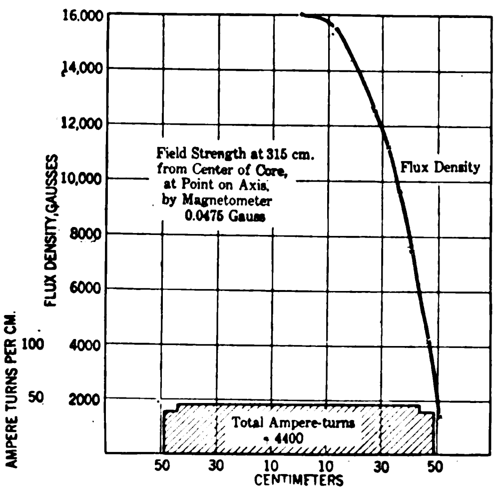

Fig. 3

In Figs. 3, 4 and 5 are shown the flux distribution in the core for three different distributions of the ampere-turns. Fig. 3 shows the flux distribution for a current of 5.98 amperes in the winding when all

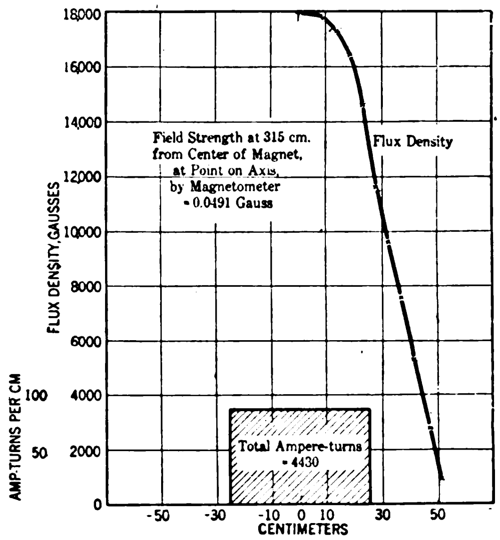

Fig. 4

the coils were connected in series (uniform distribution of ampere-turns). Fig. 4 shows the flux distribution for a current of 11.5 amperes in the 11 coils (total of 385 turns) covering the central half of the core.

Fig. 5 shows the flux distribution when the 21 coils were connected in parallel, with a suitable resistance in series with each, and the currents in these coils adjusted to give practically the same flux through each cross-section of the core. The currents in the coils were as follows:

Coil No.	1&21	2&20	3&19	4&18	5&17	6to 16
Length of coil, cm.	5.3	4.6	4.6	4.6	4.6	4.6
Amperes	51.0	2.70	2.00	1.50	1.10	0.84

The 21 coils were numbered consecutively from one end of the core to the other. The same distribution of ampere-turns would have been obtained from a series winding of 21 coils, had the coils had the following numbers of turns;[3]

Coil No.	1&21	2&20	3&19	4&18	5&17	6&16
Turns per coil	2130	112	83	63	46	35
Turns per cm.	402	24	18	14	10	7.6

The total number of coils in this equivalent winding is 5253, and the equivalent current is 0.84 amperes.

In Table I are given the calculated and observed values of the magnetizing force at a point on the axis of the core 315 centimeters from its center.

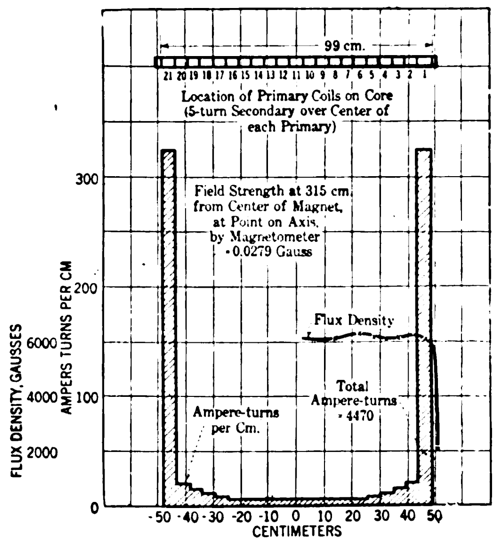

Fig. 5

TABLE I

Flux distribution	Average flux	Magnetizing force	
		Calculated	Observed
Fig. 3	99,000	0.051	0.048
Fig. 4	101,000	0.052	0.049
Fig. 5	51,000	0.026	0.028

Considering the difficulty in making accurate magnetometer measurements, the agreement between the observed and calculated values is as good as could be expected.

Average Flux in Core Due to a Given Number of Uniformly Distributed Ampere-turns

The resultant magnetomotive force acting in any line of force is always equal to the line integral of the magnetizing force (H) completely around the closed

3. These equivalent turns are taken proportional to the actual currents in the coils. The actual number of turns in each of the coils was 35. Hence the equivalent turns in coil No. 1 are $\frac{51.0}{0.84} \times 35 = 2130$.

path formed by this line, *viz.*,

$$4\,\pi\,N\,I = \int H\,d\,x \tag{7}$$

where $N\,I$ is the number of current-turns which link this line of force and $d\,x$ an elementary length in the line of force. In this expression all quantities are in c. g. s. electromagnetic units. When I is expressed in amperes, H in ampere-turns per centimeter (or inch) and x in centimeters (or inches) this expression becomes

$$N\,I = \int H\,d\,x \tag{7a}$$

Consider the special case of an iron core of length l and diameter d magnetized by a coil of N turns, uniformly distributed over its length. Referring to Fig. 2, let H_s be the magnetizing force at any point P on the axis of the core (inside or outside the space occupied by it), which the current in the solenoid which forms the winding *would* produce *were there no iron present.* The value of this magnetizing force in c. g. s. electromagnetic units is[4]

$$H_s = \frac{2\,\pi\,N\,I}{l}\left[\frac{x + 0.5\,l}{\sqrt{r^2 + (x + 0.5\,l)^2}} - \frac{x - 0.5\,l}{\sqrt{r^2 + (x - 0.5\,l)^2}}\right] \tag{8}$$

Let H_m be the magnetizing force at P due to the magnetic poles at the surface of the core. Then the resultant magnetizing force at P is

$$H = H_s + H_m$$

Equation (7), applied to this particular case, then becomes

$$4\,\pi\,N\,I = 2\int_0^{\infty} (H_s + H_m)\,d\,x \tag{9}$$

which may also be written

$$4\,\pi\,N\,I = 2\int_0^{l/2} (H_s + H_m)\,d\,x + 2\int_{l/2}^{\infty} (H_s + H_m)\,d\,x$$

When the length of the magnetizing solenoid is 10 or more times its diameter, it may readily be shown, by integrating equation (8), that

$$2\int_{l/2}^{\infty} H_s\,d\,x = \text{less than 1 per cent of } 4\,\pi\,N\,I$$

Hence, for a core whose length is 10 or more times its diameter, equation (9) becomes

$$4\,\pi\,N\,I = 2\int_0^{l/2} H\,d\,x + 2\int_{l/2}^{\infty} H_m\,d\,x \tag{10}$$

4. (See Pender, "Electricity and Magnetism for Engineers," Part I, p. 231).

As a first approximation, the magnetic poles produced on a core of uniform cross-section, magnetized by a solenoid completely covering it, may be assumed to be distributed in the same manner as the poles induced by a uniform field on an ellipsoid of revolu-

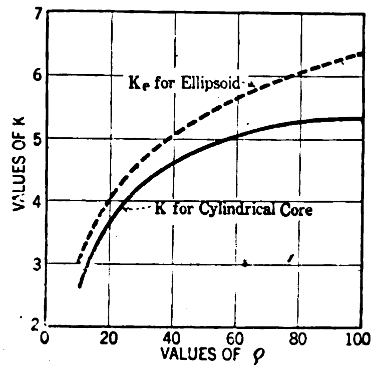

Fig. 6

tion, whose length and maximum diameter are respectively equal to the length and diameter of the rod, and in which the flux through the central cross-section has the same value as the flux through the central cross-section of the given core. Compare the dotted curve in Fig. 6 showing the flux distribution in such an ellipsoid, with the full line curve showing the actual distribution in a rod of uniform cross-section. On this assumption it may be shown[5] that, when l is greater than 10 d,

$$2\int_{l/2}^{\infty} H_m\,d\,x = \frac{B_c\,d^2}{l}\left[\log_e\left(\frac{2\,l}{d}\right) - 1\right] \tag{11}$$

where B_c is the flux density at the center of the core. In this formula all quantities are in c. g. s. electromagnetic units.

Put

$$K_1 = \left(\frac{d}{l}\right)^2\left[\log_e\left(\frac{2}{d}\right) - 1\right] \tag{12}$$

also, let H_a be the average value of the resultant magnetizing force inside the core. Then equation (10) may be written

$$4\,\pi\,N\,I = (H_a + K_1\,B_c)\,l \tag{13}$$

The average flux through a uniformly magnetized ellipsoid of revolution is equal to 2/3 of the flux through its central cross-section. This follows from the fact that the flux through any given cross-section is inversely proportional to the area of this cross-section. Hence, on the assumption that the poles on the given core are distributed in the same manner as the poles on a uniformly magnetized ellipsoid, the flux density B_c at the center of the core is equal to 3/2 times the average flux density B_a in the core. (The actual ratio for the rod in Fig. 3 is 1.36 instead of 1.50). On

5. DuBois, "The Magnetic Circuit in Theory and Practise," (1896), p. 38.

this assumption, equation (**13**) may be written

$$4\,\pi\,N\,I = (H_a + 3/2\,K_1\,B_a)\,l \qquad (\mathbf{13a})$$

Therefore, on the assumptions above stated, the magnetomotive force required to magnetize a core, by means of a uniformly wound solenoid concentric with it and of the same length as the core, is

$$4\,\pi\,N\,I = \left(H_a + \frac{K}{\rho^2}\,B_a\right)l \qquad (\mathbf{14})$$

where

$$\rho = \frac{l}{d} = \frac{\text{Length of core}}{\text{Diameter of core}} \qquad (\mathbf{15})$$

and

$$K = \frac{3}{2}\,(\log_e 2\,\rho - 1) \qquad (\mathbf{16})$$

In these equations I is in absamperes; l is the length of the core, in centimeters; d is the diameter of the core, in centimeters; H_a is the average value of the resultant magnetizing force in the core, in gilberts per centimeter; and B_a is the average flux density in the core, in gausses, *viz.*,

$$B_a = \frac{4\,\phi_a}{\pi\,d^2} \qquad (\mathbf{17})$$

where ϕ_a is the average flux through the core in maxwells.

From the experimental data given in DuBois' "The Magnetic Circuit in Theory and Practise" (p. 41), the value of the factor K for a uniform rod is somewhat less than for an ellipsoid. (The factor K is equal to $\frac{3}{8\,\pi} = 0.1194$ times the factor C employed by DuBois.) In Fig. 6 are given the values of K for a core of uniform cross-section, as calculated from DuBois' experimental data, and also the theoretical values of K for an ellipsoid.

Defining the average permeability μ of the core as the ratio of the average flux density in it to the average of the resultant magnetizing force in it, when both are expressed in c. g. s. electromagnetic units, equation (**14**) for the magnetomotive force required to magnetize the core may be written

$$4\,\pi\,N\,I = \left(\frac{1}{\mu} + \frac{K}{\rho^2}\right)B_a \qquad (\mathbf{18})$$

where μ is in c. g. s. electromagnetic units. Or, substituting for B_a its value in terms of the total average flux ϕ_a (equation **17**), this relation may be written

$$\phi_a = \frac{4\,\pi\,N\,I}{R} \text{ maxwells} \qquad (\mathbf{19})$$

$$R = \frac{4}{\pi\,d^2}\left(\frac{1}{\mu} + \frac{K}{\rho^2}\right)l \text{ oersteds} \qquad (\mathbf{20})$$

This last expression is the total reluctance of the path of the flux through the core, including both the reluctance of the core itself and the reluctance of the return circuit of the flux through the surrounding air.

The reluctance of the core itself is

$$R_i = \frac{4\,l}{\pi\,\mu\,d^2} \qquad (\mathbf{21})$$

It is interesting to note that when the permeability of the core is high, its reluctance is but a small fraction of the total reluctance of the complete magnetic circuit, even though the rod be relatively long. For example, when $\mu = 1000$ and $\rho = 20$,

$$\frac{R_i}{R} = \frac{\frac{1}{\mu}}{\frac{1}{\mu} + \frac{K}{\rho^2}} = \frac{0.001}{0.001 + \frac{3.7}{400}} = 0.0975$$

That is, under these conditions the reluctance of the rod itself is only 9.75 per cent of the total reluctance of the complete magnetic circuit.

The data given in Fig. 3 serves as an experimental check of equations (**19**) and (**20**). The permeability of the core was not measured, but a fair assumption is that it is approximately 1000. The value of ρ for the given core is $\frac{102}{3.28} = 31$. From Fig. 6 the corresponding value of K is 4.27. Whence, from equation (20) the total reluctance of the magnetic circuit is

$$R = \frac{4\,(0.001 + 0.00444) \times 102}{\pi \times (3.28)^2}$$

$$= 0.0656 \text{ oersted.}$$

For a current of 5.98 amperes in 735 turns the magnetomotive force is $4\,\pi \times 735 \times 0.598 = 5530$ gilberts. Whence from equation (**19**) the average flux is

$$\phi_a = \frac{5530}{0.0656} = 84{,}500$$

The actual value of ϕ_a was 99,000. Considering the uncertainty in the assumed value of μ, this may be considered a fairly satisfactory check of equation (**20**).

Comparing Figs. 3 and 4 it is evident that the flux distribution in the core is approximately the same for a winding covering the central half as for a winding covering the entire length of the core. Consequently, equation (**20**) may also be applied, with a fair degree of approximation, even when the winding covers only half the total length of the core. That is, for the same total ampere-turns, the average flux is approximately independent of the axial length of the winding, provided this winding is uniformly distributed over the central portion of the core. This is entirely in accord with the experimental data given in Figs. 3 and 4, *viz.*, the total ampere-turns in the two cases

are 4400 and 4430 respectively, and the average fluxes 99,000 and 101,000 respectively.

SOLUTION OF PROBLEM A. Combining equations (**6**) and (**19**) it follows that the magnetizing force produced at the point P on the axis of a straight core magnetized by a current of I absamperes in a uniformly wound solenoid completely covering this core is,

$$H = \frac{2\,N\,I\,l}{x^3\,R}$$

$$= \frac{\pi\,N\,I\,d^2}{2\,x^3\left(\dfrac{1}{\mu} + \dfrac{K}{\rho^2}\right)} \text{ gilberts per cm.} \qquad (\mathbf{22})$$

where all quantities are in c. g. s. electromagnetic units. This formula is of course applicable only when the point P is at a distance from the center of the core large in comparison with the length of the core.

When I is in amperes, the last relation becomes

$$H = \frac{N\,I\,d^2}{6.37\,x^3\,(1/\mu + K/\rho^2)} \text{ gilberts per cm.} \qquad (\mathbf{22a})$$

In this expression I is the current in the winding, in amperes; N is the number of turns in the winding; d is the diameter of the core, in centimeters; x is the distance of the point P from the center of the core, in centimeters, μ is the average permeability of the core, in c. g. s. electromagnetic units; ρ is the ratio of the length to the diameter of the core, and K is a factor whose value is given by the lower curve in Fig. 6.

Equation (**22**) applied to core and winding corresponding to Figs. 3 and 4 gives for H at a point 315 centimeters from the core the value 0.044 (as compared with 0.048 observed) when the winding completely covers the core (Fig. 3); and the value 0.044 (as compared with 0.049 observed) when the winding covers only the central half of the core (Fig. 4). The permeability is assumed to be 1000 in each case.

PROBLEM B. The self-inductance L of a winding is, by definition, equal to the flux linkages of this winding per unit current in it. When the successive turns of a winding of N turns are all threaded by the same number of lines of force ϕ, the flux linkages are $\lambda = N\,\phi$. When the successive turns are not threaded by the same number of lines of force the flux linkages are

$$\lambda = \phi_1 + \phi_2 + \phi_3 \; . \; . \; . \; . \; \phi_n$$

where ϕ_1, ϕ_2, ϕ_3, etc. are the number of lines of force which thread the successive turns.

Consider the special case of a uniformly wound solenoid of N turns and of axial length l. Let $d\,x$ be the width of a group of turns at an axial distance x from the center of the solenoid, and let ϕ be the flux through this group of turns. The number of turns in the length $d\,x$ is $N/l\;d\,x$. Whence the flux linkages of these turns are

$$d\,\lambda = \frac{N}{l}\,\phi\,d\,x$$

and the total flux linkages of the entire solenoid are

$$\lambda = 2\,\frac{N}{l}\int_0^{l/2} \phi\,d\,x$$

Let ϕ_a be the average value of the flux through the turns which make up the solenoid. Then

$$\int_0^{l/2} \phi\,d\,x = \phi_a\,\frac{l}{2}$$

The total flux linkages of the solenoid are therefore

$$\lambda = N\,\phi_a$$

Let I be the current required to produce the average flux ϕ_a. Then the self-inductance of the solenoid is

$$L = \frac{N\,\phi_a}{I} \text{ abhenries} \qquad (\mathbf{23})$$

where ϕ_a is in maxwells and I in absamperes.

Equation (**23**) is directly applicable to a uniformly wound solenoid on an iron core of the same length as the solenoid. Neglecting the axial component of the flux in the air between the surface of the core and the mean circumference of the solenoid, the average flux which links the turns of the solenoid may be taken equal to the average flux in the core, *viz.*, to the value of ϕ_a given by equation (**19**). Whence, for such a winding the self-inductance is

$$L = \frac{4\,\pi\,N^2}{R} \text{ abhenries} \qquad (\mathbf{24})$$

where R is given by equation (**20**).

The reactance of this winding to a voltage of frequency f is $X = 2\,\pi\,f\,L \times 10^{-9}$ ohms. Neglecting the resistance of the winding, the volt-amperes required to produce in it a current whose *maximum* value is I *absamperes* is

$$\text{Volt-amperes} = X\left(\frac{1}{10} \; . \; \frac{I}{2}\right)^2$$

$$= \frac{4\,\pi^2 f\,(N\,I)^2}{R} \times 10^{-7} \qquad (\mathbf{25})$$

In this equation R is the reluctance in oersteds, as given by equation (**20**). Substituting for $(N\,I)$ its value from (**22**) and for R its value from equation (**20**), there results

Volt-amperes

$$= \frac{4\,\pi\,f\,x^6}{l\,d^2}\left(\frac{1}{\mu} + \frac{K}{\rho^2}\right) H^2 \times 10^{-7} \qquad (\mathbf{26})$$

This formula gives the volt-amperes necessary to produce a magnetizing force of H gilberts per centi-

meter at a point on the axis of a straight core, at a distance of x centimeters from the center of the core, the core being uniformly wound throughout its length. The other symbols in the formula are l = length of core in centimeters, d = diameter of core in centimeters, $\rho = l/d$, K = a factor given by the lower curve in Fig. 6, μ = the average permeability of the core, f = the frequency in cycles per second.

The volume of the core is

$$V = l\left(\frac{\pi}{4}\,d^2\right) = \frac{\pi\,l\,d^2}{4} \text{ cu. cm.}$$

Whence equation (**26**) may also be written

$$\text{Volt-amperes} = \frac{\pi^2 f x^6}{V}\left(\frac{1}{\mu} + \frac{K}{\rho^2}\right) H^2 \times 10^{-7} \qquad \mathbf{(26a)}$$

where V is the volume of the core in cubic centimeters. Note particularly that for a core of given dimensions and given permeability the volt-amperes required are proportional to the *square* of the magnetizing force which it is desired to produce and to the *sixth* power of the distance of the given point from the center of core. Also, for a given volume of core, the longer the core in comparison with its diameter, the more effective will it be.

For example, consider a core 50 feet long and 1 foot in diameter, whose average permeability is 1000 c. g. s. electromagnetic units. The volt-amperes at 25 cycles required to produce a magnetizing force of 0.2 gilberts per centimeter (equal approximately to the horizontal component of the earth's magnetic field) at a point 150 feet from the center of the core (and on its axis) are

$$\frac{4\,\pi \times 25 \times (150 \times 30.48)^6}{(50 \times 30.48)\,(30.48)^2}\left[\frac{1}{1000} + \frac{4.85}{(50)^2}\right] \times (0.2)^2 \times 10^{-7}$$

= 23,900,000 volt-amperes, or 23,900 kilovolt-amperes. To produce this same field intensity 300 feet from the center of the magnet would require 64 times as many kilovolt-amperes, or 1,530,000 kv-a. Or, for the same kilovolt-amperes (23,900), the magnetizing force 300 feet from the center of the magnet would be $1/2^3 = 1/8$th the intensity of the horizontal component of the earth's field.

PROBLEM C. Equation (**23**) is applicable not only to the uniform winding covering the entire length of core, but also to a uniform winding covering only a portion of the core, provided ϕ_a in this equation is taken, not as the average flux for the entire core, but for that particular portion which is covered by the winding. Referring to Fig. 4, the average flux through the central portion of the core covered by the winding (namely, the central 51 centimeters of the core) is the average of ϕ between the limits $x = 0$ and $x = 25.5$. This average flux is 142,000. The self-inductance of this winding (385 turns) is then, from equation (**23**),

$$L_4 = \frac{3.85 \times 142{,}000}{1.15} \text{ abhenries} = 0.0475 \text{ henries}$$

The self-inductance of the uniform winding (735 turns) covering 98 centimeters, or 96 per cent of the length of the core (Fig. 3) is

$$L_3 = \frac{735 \times 102{,}000}{0.598} \text{ abhenries} = 0.125 \text{ henries}$$

Currents of 5.98 and 11.5 amperes respectively in these two windings produced substantially the same external magnetic field. Hence, designating the volt-amperes for the two cases P_4 and P_3 respectively, and noting that

$$P_4 = 2\,\pi f L_4 \times 10^{-9}\left(\frac{1}{10}\;\frac{11.5}{\sqrt{2}}\right)^2$$

$$P_3 = 2\,\pi f L_3 \times 10^{-9}\left(\frac{1}{10}\;\frac{5.98}{\sqrt{2}}\right)^2$$

there results

$$\frac{P_4}{P_3} = \frac{0.0475}{0.125}\left(\frac{11.5}{5.98}\right)^2 = 1.40$$

The core which has a winding covering only its central half therefore requires, to produce the same external magnetic field, 40 per cent more volt-amperes for excitation than the core which is uniformly wound throughout its entire length. The exact percentage difference will of course depend upon the permeability and the relative dimensions of the ore. However, irrespective of the permeability and dimensions, the short winding will always require more volt-amperes, due to the fact that the average flux which links its turns is always greater than the average flux for the entire length of the core.

When the winding is so distributed as to give a practically constant flux through each cross-section of the core, as in Fig. 5, its self-inductance is

$$L_5 = \frac{N\,\phi}{I}$$

where N is the total number of turns in the winding and I the current. The self-inductance of the winding corresponding to Fig. 5 is therefore

$$L_5 = \frac{5253 \times 51{,}500}{0.084} \text{ abhenries} = 3.22 \text{ henries}$$

The magnetizing force produced by a current of 0.84 amperes in this winding, at a point on the axis of the core 315 centimeters from its center, was 0.028, as against 0.048 for a current of 5.98 amperes in the uniform winding of 735 turns covering the entire length of core. Neglecting variations in permeability, the current required in the full-length uniform winding, to produce a magnetizing force of 0.028, would be

$\frac{0.028}{0.048} \times 5.98 = 3.49$ amperes. Hence, for the external magnetic field, the relative volt-amperes required for the two windings would be in the ratio of

$$\frac{P_5}{P_3} = \frac{3.22}{0.125} \left(\frac{0.84}{3.49} \right)^2 = 1.49$$

A lumped winding at the two ends of the core therefore also requires more volt-amperes for excitation than a uniform winding covering the entire length of the core.

For the maximum external field per volt-ampere of excitation, the winding should therefore cover the entire length of the core and be uniformly distributed.

PROBLEM D. The volume of an ellipsoid of revolution, of a given length and maximum diameter is 2/3 of a volume of a cylinder of the same length and same diameter. Assuming a uniformly wound solenoid to produce a uniform magnetic field in the space enclosed by its winding (which is approximately true except for the region near its two ends), the ampere-turns required to magnetize such a core are, from equation (**13**),

$$4 \pi N I = (H_a + K_1 B_c)$$

where K_1 is given by equation (**12**) and

$$B_c = \frac{4 \phi_c}{\pi d^2}$$

and ϕ_c is the flux through the central cross-section of the ellipsoid. This maximum flux ϕ_c is equal to 3/2 times the average flux ϕ_a through the ellipsoid. Also, $H_a = \frac{B_c}{\mu}$. Whence

$$4 \pi N I = \frac{6}{\pi d^2} \left(\frac{1}{\mu} + K_1 \right) \phi_a$$

and therefore

$$\phi_a = \frac{4 \pi N I}{R_e} \tag{27}$$

where

$$R_e = \frac{4}{\pi d^2} \left(\frac{3}{2 \mu} + \frac{3}{2} K_1 \right)$$

As before equation (**16**), put

$$K_e = \frac{3}{2} \left[\log_e 2 \rho - 1 \right]$$

(The subscript "e" is here used to designate that this value of K refers to an ellipsoid). Then

$$R_e = \frac{4}{\pi d^2} \left(\frac{3}{2 \mu} + \frac{K_e}{\rho^2} \right) \tag{28}$$

The value of K_e for an ellipsoid is given by the upper curve in Fig. 6.

Comparing equation (**28**) with equation (**20**), and noting that K_e for an ellipsoid is greater than K for a cylinder, it is evident that, although the volume of an ellipsoid of revolution is less than the volume of a cylinder of the same length and cross-section, the reluctance of the complete path of the flux in the case of the ellipsoid is greater than the reluctance of the complete path of the flux in the case of a cylinder. This greater reluctance is due to the fact that the flux density in an ellipsoid has the same value throughout its length, whereas in a cylindrical core the *average* flux density is only about 2/3 of the value at the center.

The self-inductance of a uniform winding covering the entire length of an ellipsoidal core is

$$L = \frac{N \phi_a}{I}$$

where I is the current and ϕ_a the average flux through the core. Substituting for ϕ_a its value from equation (27), there results

$$L = \frac{4 \pi N^2}{R_e}$$

From equation (**25**) the volt-amperes required for excitation, to produce a maximum current of I absamperes, is then

$$\text{Volt-amperes} = \frac{4 \pi^2 f (N I)^2}{R_e} \times 10^{-7} \tag{29}$$

where I is in absamperes (maximum value) and R is in oersteds. Substituting for $(N I)$ its value from (**27**) there results

$$\text{Volt-amperes} = \frac{f R_e}{4} \phi_a^2 \times 10^{-7}$$

Substituting for ϕ_a its value from equation (**6**), and for R_e its value from (**28**), there results

$$\text{Volt-amperes} = \frac{4 \pi f x^6}{l d^2} \left(\frac{3}{2 \mu} + \frac{K_e}{\rho^2} \right) H^2 \times 10^{-7} \tag{30}$$

The volume of an ellipsoid of revolution is

$$V = \frac{\pi}{6} l d^2$$

Whence equation (**30**) may be written

Volt-amperes

$$= \frac{\pi^2 f x^6}{V} \left(\frac{1}{\mu} + \frac{2}{3} \frac{K_e}{\rho^2} \right) H^2 \times 10^{-7} \tag{30a}$$

Comparing this expression with equation (**26a**) for a cylindrical core it is evident that for the same volt-amperes and same volume of iron, the magnetizing force H_e produced at a point at a given distance x from the center of an ellipsoid core, and the magnetizing force H produced at a point at an equal distance from the center of a cylindrical core, are in the ratio

$$\frac{H_e}{H} = \sqrt{\frac{\frac{1}{\mu} + \frac{K}{\rho^2}}{\frac{1}{\mu} + \frac{2}{3}\frac{K_e}{\rho^2}}} \quad (31)$$

For example, for $\mu = 1000$ and $\rho = 31$, $K = 4.27$ and $K_e = 4.70$. Whence

$$\frac{H_e}{H} = 1.13$$

For these conditions the effectiveness of the ellipsoid core is only 13 per cent greater than that of a cylindrical core. This gain would hardly justify the labor involved in tapering the core.

As a rough experimental check on the effect of tapering a core, the core of iron wires above described was excited by a current of 10 amperes in a coil covering the central 61 centimeters of its axial length. The magnetizing force at a point 300 centimeters from the center of the core was measured by means of a magnetometer, and found to be 35.2 units (arbitrary scale). The core was then tapered at each end (by cutting off the wires of successive layers to different lengths), making a taper from 3.28 to 2.1 centimeters in a distance of 19 centimeters. The magnetizing force at the same point as before for the same current in the winding (10 amperes) was found to be reduced to 33.7 units (on the same arbitrary scale). The decrease in the volume of the core was 11.3 per cent, and the decrease in the magnetizing force was 4.3 per cent.

Since for a fixed number of volt-amperes the magnetizing force at the external point varies as the *square-root* of the volume of the core (equation **30a**), had the tapered core been of the same volume as the cylindrical core, (*i. e.*, increased from a volume of 0.87 to 1.00, or 15 per cent) the magnetizing force for the same number of volt-amperes in the two cases would have been in the ratio of

$$\frac{H_t}{H} = \frac{(33.7)\sqrt{1.15}}{35.2} = 1.03$$

That is, for the same volume and same volt-amperes the tapered core used in the experiment would have produced a magnetizing force only 3 per cent greater than a cylindrical core.

REORGANIZATION OF NELA RESEARCH LABORATORIES

Nela Research Laboratory was organized in 1908 under the Directorship of Dr. Edward P. Hyde as The Physical Laboratory of the National Electric Lamp Association. The name was changed to Nela Research Laboratory in 1913, when the National Electric Lamp Association became the National Lamp Works of General Electric Company. For some years the Laboratory was devoted exclusively to the development of those sciences on which the art of lighting has its foundation, but in 1914 the functions of the Laboratory were extended by the addition of a small Section of Applied Science, which had an immediate practical objective.

The Section of Applied Science is now being largely extended as a separate Laboratory of Applied Science under the immediate direction of Mr. M. Luckiesh, who becomes Director of Applied Science, and a new building is being constructed to house this branch of the work, which will be carried forward with a staff of several physicists, an engineer, an architect and a designer, together with the necessary technical and clerical assistants.

Dr. Ernest Fox Nichols, formerly President of Dartmouth College, and more recently Professor of Physics at Yale University, has accepted an invitation to assume the immediate direction of the Laboratory of Pure Science under the title of Director of Pure Science. The work of this Laboratory, which will be continued in the present building, will be somewhat further extended under the new organization.

The Laboratory of Pure Science and the Laboratory of Applied Science will together constitute the Nela Research Laboratories, and will be co-ordinated under the general direction of Dr. Hyde, who becomes Director of Research.

INVESTIGATIONS IN ELECTROLYSIS

Early in the year, definite arrangements were made with the American Committee on Electrolysis, which represents all of the great national associations of utility companies, for cooperative work between that Committee and the Bureau of Standards in conducting an extensive research in the field of electrolysis mitigation. After this arrangement had been made, the Committee asked the Bureau to outline a program of research work to be carried out jointly, and such a program was formulated by the Bureau and approved by the Committee.

During the last four months a number of somewhat extended investigations have been carried out in cooperation with this Committee in several middle Western cities. This work has been confined largely, and almost exclusively, to the effect of pipe drainage on underground systems, especial attention being given to the possibility of joint electrolysis on high resistance joints and interchange of current between drained systems. Some attention has also been given to the three-wire systems of power distribution and also to automatic substation installations as a means of electrolysis mitigation. This joint investigation is an extremely important one and it is hoped that means will be found for continuing it during the coming year.

The Current-Carrying Capacity of Lead-Covered Cables

BY RALPH W. ATKINSON

Standard Underground Cable Co., Perth Amboy, N. J.

This article gives data whereby the carrying capacity of lead-covered cables can be calculated on the basis of thermal limitations. Carrying capacity as limited by voltage drop or economical considerations is not discussed. The article shows how further data can be applied as these are determined.

An appendix contains some numerical examples illustrating the use of the data. It also contains a chart by which it is possible to determine graphically, for given conditions, the carrying capacity of three-conductor paper and varnished cloth cables installed in conduits.

There is also included a chart illustrating the relation between the various temperatures and temperature rises of a group of lead-covered cables.

THE load that a cable may safely carry is dependent upon properties intrinsic to the cable itself and upon the temperature of the immediate surroundings of the cable. The properties of the cable which affect its carrying capacity are the maximum allowable operating temperature and the temperature rise—due to the load—of the conductor above the temperature of the cable surroundings.

Maximum Allowable Operating Temperature. The American Institute of Electrical Engineers has recommended the following as the safe limits of maximum allowable operating temperature for various kinds of insulation.

Paper..............(85 deg. cent. – E)
V. C................(75 deg. cent. – E)
Rubber.............(60 deg. cent. – 0.25 E)

Where E is the r. m. s. of the operating voltage in kv. between conductors.

Abnormal temperatures seriously affect either—or both—of the electrical and mechanical properties of the dielectric of high and low-voltage cables. Most of the effect upon the electrical properties is an indirect result of the effect of heat upon their mechanical properties. A low-voltage cable may sustain a great amount of damage to the dielectric and still be entirely serviceable—if undisturbed. However, the higher the operating voltage of the cable, the less the degree of damage which the cable may sustain and still be likely to continue in successful operation.

Therefore whatever may be judged to be the allowable limit of temperature at which low-voltage cable may operate, necessarily a more strict limitation must be placed upon the temperature at which a high-voltage cable may operate, and the higher the voltage of the cable, the lower will be the allowable temperature limit.

Apart from the physical condition of the dielectric as affected by temperature, a very important consideration is that the dielectric losses are proportionally very much greater at higher temperatures. This is of no practical importance in low-voltage cables but in the case of high-voltage cables may sometimes set a definite limit lower than that set by other causes.

The temperature limits given by the A. I. E. E. rules, for cables operating at different voltages, are entirely rational, in the light of the present development of the art. However, different service conditions may warrant variation from rules which apply to general conditions; thus cables installed under extraordinarily severe conditions, perhaps cannot be expected to have a long life and may justifiably be operated at temperatures that will be known to produce a short life.

The Base Temperature. An unloaded cable will normally assume the temperature of the medium in which it is placed. Thus, a cable that is carrying no load when placed in water, will assume the temperature of the water. If placed in air, it will assume the ambient temperature of the air, unless it receives radiated heat from some hot body such as the sun. Likewise, an unloaded cable when placed in the earth or in a conduit will assume the temperature of the earth.

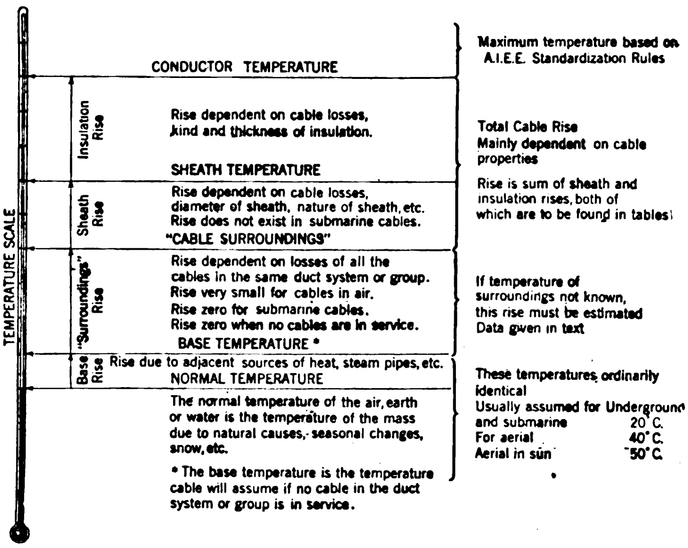

FIG. 1—CHART ILLUSTRATING THE RELATION BETWEEN THE VARIOUS TEMPERATURES AND TEMPERATURE RISES IN LEAD-COVERED CABLES

In some places the presence of steam pipes, furnaces, etc., may cause the temperature of the earth to exceed the normal earth temperature, the normal temperature being that due to natural causes.

The temperature which an unloaded cable or group of cables assumes when placed in position to operate will be called its "Base Temperature".

Temperature Rise Caused by Load. If load is now applied to the cables heat is generated and must be dissipated through the surrounding media. This will cause the cables to rise in temperature.

The rise in temperature of the cables may be divided into three parts; the rise of the conductor temperature above sheath temperature; the rise of sheath temperature above the temperature of surroundings; and the rise of the surroundings above the base temperature.

Temperature Rise of Conductor. The rise in temperature of the conductor above the sheath is a function of the thickness and kind of insulation and of the load upon the cable. It is easily found by laboratory experiment and as it is practically independent of conditions external to the cable it forms a very convenient basis for calculation.

Temperature Rise of Sheath. The temperature rise of the sheath above the cable surroundings is a function of the diameter of the cable, the nature of the sheath surface and cable surroundings and of the load upon the cable.

The effect of the surroundings upon this rise is illustrated by the fact that for a cable lying in water there is little surface resistance between the cable sheath and the water so that the sheath will assume a temperature so near that of the water that the difference may usually be disregarded.

Total Cable Rise. Since the temperature rise between the inner and outer surfaces of the sheath is very small it may be neglected and the sum of the conductor rise above sheath temperature plus the temperature rise of the sheath above the temperature of the surroundings constitutes the entire rise of the conductor above the cable surroundings. (Insulation rise plus sheath rise). This rise will be called the total cable rise.

Rise of Cable Surroundings. If the medium surrounding a cable is free to flow as where the cable is placed in free air or water, heat is readily carried away from it and there is little or no rise of the surrounding medium. This does not apply where a large number of cables are closely placed together in air.

If, however, a cable or group of cables is placed in the earth, there is a rise in temperature of the surroundings because of their thermal resistance. This rise in temperature of the surroundings is, as a first approximation, proportional to the total energy dissipated by all the cable in the immediate vicinity, or in the same conduit system. We can therefore say that for a given type and size of conduit structure the temperature rise of the system is equal to a certain number of degrees per watt loss per foot of duct structure. This rise in degrees cent. per watt per foot of duct structure will be called the "Heating Constant" of the duct system.

There are not at present sufficient data available to permit the giving of accurate numerical values for this factor for different conditions. The data which are available indicate that it will usually fall between the limits 0.6 to 1.6 depending upon the size of duct structure and upon the nature of the surrounding soil. One (1.0) seems to be a good and reasonably safe average figure for a conduit containing up to say 16 ducts surrounded by earth with a normal amount of moisture. More data should be obtained showing the effect of different soil conditions and of the size and shape of the conduit system upon the average constant of the structure. Also these data should show how the constant for different parts of the cross-section varies and how it is affected by the distribution of the cables in the structure. The heating constant multiplied by the watts loss per foot of all the cables in the conduit gives the temperature rise of the cable surroundings.

The Temperature of the Cable Surroundings. The temperature of the surroundings is equal to the temperature rise of these surroundings added to the base temperature.

Because of the insufficient data pertaining to the heating constant, the most accurate results can be obtained from the data here presented only when the temperature of the cable surroundings is known or can be measured.

For a cable installed in a duct, the "surrounding temperature" is taken as that of the duct wall and not that of the air in the duct. It is not practical to measure the temperature of the air in the duct since a measurement of this may give anything between the temperature of the cable sheath and that of the duct wall. Also it has been shown by experiment that normally the rise of a cable over the duct wall temperature is very nearly the same as the rise over ambient air temperature of a similar cable with the same load but suspended in free air.

Measurement of Duct Temperatures. Usually the temperature of the duct walls surrounding any cable may be determined with good accuracy by measuring the temperature in an adjacent idle duct at the same distance from the outside of the conduit or one adjacent but nearer the center of the conduit system. In the former case, the temperature of the idle duct will be lower by a very small amount and in the latter case the temperature of the idle duct will be very nearly the same as the walls of the working duct.

Another way of measuring the duct wall temperature is actually to make the measurement within the working duct, but after cutting off the current and voltage within from one-half to one hour. This is allowable on account of the relatively great amount of time required by a duct system to change its temperature. If the temperature is measured while the cable is working, it is not known what temperature is being measured. (See Atkinson & Fisher A. I. E. E. 1913).

The Total Allowable Temperature Rise of Cable. If the maximum allowable operating temperature is

known or assumed, and the temperature of the cable surroundings is known, the total allowable rise of the cable is found by subtracting the temperature of the surroundings from the maximum allowable temperature. Where the temperature of the surroundings is not known and must be estimated, the total allowable rise of cable and surroundings is found by subtracting the base temperature from the maximum allowable temperature. When the sheath temperature is known the maximum rise of the conductor over the sheath temperature is found by subtracting the temperature of the sheath from the maximum allowable temperature. Obviously, the carrying capacity of a cable is limited by its hottest portion. Hence, the maximum allowable temperature rise must be figured for that portion of the cable lying in the hottest surroundings.

The Losses. The losses that cause the rise in temperature of a cable are the conductor $I^2 R$ loss (including skin effect and eddy current losses in the conductor), dielectric loss, and sheath current loss.

The conductor $I^2 R$ loss normally is by far the largest of the above losses; in fact, often this loss only, need be considered as affecting the current-carrying capacity of a cable. This loss is proportional to the conductor resistance and to the square of the current. The skin effect and eddy current losses may be considered simply as increasing, by a certain amount, the conductor resistance. That is, the conductor may be considered to have an effective resistance sufficient to account for all the losses within it. The conductor loss produces rise in all parts of the heat path, conductor above sheath, sheath above ambient air, or duct wall, and rise of duct above base temperature for underground cables.

Dielectric losses affect the sheath and conductor rise exactly as do an equal amount of conductor loss. Unless the dielectric losses are very large no important error is introduced by considering that their effect upon the insulation and conductor rise is the same as an equal amount of conductor loss. Where the rise inside the sheath due to dielectric loss is large, no accurate general rule for determining that rise can be made.

Sheath losses produce no rise of the conductor above sheath but affect the sheath rise and duct rise in exactly the same way as an equal loss in the conductor. Sheath losses are important normally only in single-conductor a-c. cables.

Calculation of Carrying Capacity. The general method of procedure is practically the same in every case. First the total rise caused by a known loss is found and from this the loss is calculated which will produce the maximum allowable rise. From this the allowable current is calculated.

Consider as a specific case a three-conductor low-voltage cable operating in free air. The recommended maximum operating temperature is fixed by the kind of insulation and the operating voltage. The allowable temperature rise is found by subtracting the ambient air temperature from the recommended operating temperature. From tables I and II the rise in temperature of the conductor above sheath due to a given number of watts loss is found. From the same tables the rise in temperature of the sheath above ambient air temperature is found for the same watts loss. The sum of these temperature rises gives the total temperature rise produced by this amount of loss.

A three-conductor cable normally has very little sheath loss. The total losses in this case are considered as conductor $I^2 R$.

TABLE I
THREE-CONDUCTOR CABLES INSULATED WITH 3/32-IN. PLUS 3/32-IN. PAPER.

* Conductors smaller than No. 4 are figured as solid.

In figuring the current to produce the watts as $I^2 R$ loss the resistance of the conductor was calculated at 65 deg. cent. which is near the operating temperature. An allowance of 3 per cent in resistance was made for stranding and cabling.

Column 3 of tables I and II gives the current which will produce the above number of watts as $I^2 R$ loss. The total rise due to this current being known, the current which will produce the total allowable temperature rise is found by multiplying the table current by the square root of the ratio of the allowable temperature rise to the rise produced by the table current.

Effect of Dielectric Loss. As this is a low-voltage cable dielectric losses are neglected. Had it been a high-voltage cable with dielectric losses present in important amount the procedure would have been slightly changed.

It is assumed that the amount of the dielectric loss at the operating voltage and temperature is known. After finding the temperature rise caused by the table watts the temperature rise caused by the dielectric loss is found by direct proportion and subtracted from

the total allowable rise. This leaves the allowable rise that may be caused by conductor $I^2 R$ loss. The permissible current is then found in the same way as before.

Effect of Sheath Losses. Had this been a single-conductor cable with sheath loss present in known amount, the procedure would have been similar except as follows. The sheath loss varies as the square of the conductor current and can therefore be expressed in per cent of the conductor loss. When sheath loss is present the total sheath rise is the rise produced by the conductor loss increased by this percentage.

Submarine Cable. Had this cable been installed in water the sheath rise would have been neglected; with this exception, the method is the same as before.

Where cables are already installed in ducts and already operating the problem often is to find the working temperature corresponding to the load being carried on the cables. The duct wall temperature under operating conditions should first be measured. The conductor rise and sheath rise for table current are then found. The sum of these rises multiplied by the square of the ratio of the current in the cables to the table current, gives the total cable rise produced by the load current. If the cables are operating at high voltage the rise caused by the dielectric losses (which must be known) at this temperature is found and also added. If this rise is enough to further influence the loss, further allowance must be made for this. Final determination can usually be found readily by very little "cut and try".

Cables Installed in Conduits. The carrying capacity of a number of cables in a duct structure is calculated in the following manner.

If the duct wall temperature is not known the total allowable rise is found by subtracting the base temperature from the recommended maximum operating temperature.

The conductor rise and sheath rise caused by the table current is found as before. The rise of the surroundings due to this current is found by multiplying the total loss per foot in all the cables in the duct structure by the "Heating Constant."

The sum of these three rises gives the total rise caused by the table current. The permissible current is then found by multiplying the table current by the square root of the ratio of the total allowable rise to the rise (including rise of surroundings) produced by the table current.

Dielectric losses and sheath losses are taken care of in the same manner as before, remembering that these also affect the rise of surroundings.

Artificial Means of Cooling. When it is necessary to transmit very large amounts of power in a single conduit structure, artificial means of cooling may be required. The carrying capacity of a duct structure already fully loaded with cables often may be increased considerably by forcing air through the ducts. This is done by installing suitable fans at alternate manhole openings. The air cools the ducts not only by carrying away the heat but also by reducing the temperature difference between the sheath and duct wall.

Under proper conditions a much more effective method is that of cooling by water. This may be done either by actually allowing the water to flow through the ducts or by allowing it to moisten the earth around the structure, thus greatly decreasing the heating constant.

Of course many practical difficulties stand in the way of common application of these methods.

Effect of Load Factor. Cables installed in air, submarine cables, and single cables installed in a conduit system reach their maximum temperature quickly

after load is applied and hence their carrying capacity for loads of one or two hours duration, is not materially increased over that for continuous loads. A conduit system has relatively a very high heating capacity and takes many times as long to reach its final temperature. Hence in a conduit system where the duct rise is a large portion of the total rise the duct rise is decreased by low load factor. Thus the reduction of carrying capacity caused by conduit heating by the group of cables is less for intermittent than for continuous loading.

With proper data concerning this effect the numerical calculation may be made in the same manner as for a decrease in heating constant.

See Atkinson and Fisher, A. I. E. E. 1913.

The Tables. The original data for these tables were obtained from direct experiment, that is temperature rise measurements on a number of different sizes of cables and with different insulation thicknesses. The data have now been correlated on the basis of a definite thermal resistivity of the insulation and surface resistivity of the sheath. In so doing use has been made of the paper by the writer in the June 1919 PROCEEDINGS which gives the relation between resistances and resistivities of three-conductor cables.

The specific value of thermal resistivity used in the tables (900 centigrade degrees per watt centimeter) is a representative value for saturated paper insulation. Correction for other values than 900 may readily be made by direct proportion. Varnished cambric has about the same value as has paper. The value for rubber may be taken as about 650.

The value of surface resistivity used is 1200 degrees per watt per square centimeter. This corresponds to the value for a clean bright sheath. The rise is about 20 per cent lower for a sheath properly painted black.

Accuracy of Method. The experimental basis for the tables was obtained with cables suspended in air and with the copper at a high temperature, that is, with a high cable rise. The currents in the tables are figured on the basis of copper resistance at 65 deg. cent. The tables are therefore correct for high cable rise and 65 deg. cent. maximum temperature.

If conditions are such that the maximum temperature remains unchanged but that the surrounding temperature increases, there will be some error in the assumption that the temperature rise varies directly as the loss. The maximum percentage error occurs however for the lowest temperature rise and the absolute amount of the error is never large. Thus the cable rise is quite properly taken as proportional to the loss or to the square of the current.

If conditions are such that the maximum operating temperature varies much from 65 deg. cent., it will be found that the effect of the change in copper resistance is in the opposite direction to that produced by change in the thermal resistance of the surface of the sheath. The cable rise for the same current will not be greatly altered. The duct rise, however, will increase with the total losses even faster perhaps than in direct proportion, due to the drying effect of the high temperature upon the ducts and hence the duct rise should be calculated as proportional to the actual losses.

From data on duct rise which are now being obtained a supplementary article will be prepared showing the effect upon the heating constant of distribution of load in the conduit and also of the shape of the daily load curve.

Three-Conductor Current and Watts to Give 25 Deg. Cent. Rise. Table I gives for a three-conductor cable insulated with $\frac{3+3}{32}$ paper, the watts loss in the conductors required to raise them 25 deg. cent. above the temperature of the cable surroundings, where the cable is freely suspended in air. The table also gives the current that would produce the above watts per foot as conductor $I^2 R$ loss with the copper at 65 deg. cent.

Three-Conductor Rise With Various Insulation Thicknesses. Table II shows for three-conductor cable the effect of insulation thickness upon cable temperature rise. The temperature rise of the conductor over sheath temperature, produced by the watts in table I is given for various thicknesses of insulation.

This table also gives the sheath rise over surroundings for cables with various thicknesses produced by the watts from table I.

The second part of this table gives similar data for sector cable. It will be noted that the insulation and sheath rise for the sector cables are quite different from those for round cables with the same insulation thickness and conductor area, but that the sums of these rises are nearly the same. The maximum difference between the total cable rises is about 7 per cent in favor of the sector. This would mean a maximum of about 3 ½ in carrying capacity for a cable installed in air. For most sizes the difference is of no consequence. For cables installed in ducts, the difference is still further reduced.

Unequal Belt and Conductor Insulation. The direct values given in the table are for cables having equal belt and conductor insulation. However, the values for a cable having unequal belt and conductor insulation can easily be found by the following simple rules. The temperature rise of conductor above sheath, varies but little as long as the total insulation between the conductor and the sheath does not change. Thus a No. 0000 cable insulated with $\frac{8+4}{32}$ paper will have nearly the same insulation rise as a No. 0000 cable insulated with $\frac{6+6}{32}$ paper.

The rise of temperature of the sheath of a cable is

* Conductors smaller than No. 4 are figured as solid.

dependent on the sheath diameter and not upon the distribution of the insulation. Therefore, to find the sheath rise of a cable with insulation divided unequally between conductor, and belt, simply find by use of the table the rise for a cable of equal belt and conductor insulation of the same diameter.

The chart which immediately follows the tables gives directly the diameters of cables having unequal belt and conductor insulation in terms of the diameter of a cable having equal belt and conductor insulation.

Single-Conductor Watts and Current to Give 25 Deg. Cent. Rise. Table III gives for a single-conductor cable insulated with 4/32-in. paper the watts required to produce a 25 degree centigrade rise of conductor over cable surroundings. The currents necessary to produce these watts as $I^2 R$ loss are also given.

TABLE V

ROUND DUPLEX CABLES

Single-Conductor Rise with Various Thicknesses of Insulation. Table IV shows the effect of different thicknesses of insulation on the conductor and sheath rise of single-conductor paper cables.

Different thicknesses of lead will have slight effect upon the sheath rise.

Two-Conductor Cables. Though not as widely used as the single and three-conductor forms, two-conductor cables are of sufficient importance to warrant special mention. The common forms are named for the shape of the sheath, "round" and "flat", the latter having a sheath of an oblong or sometimes a figure 8 shape. Tables V and VI respectively give data for cables of these forms. Not as many experimental data are available for these as for one and three-conductor

TABLE IV—SINGLE-CONDUCTOR CABLES

A. Temperature rise of conductor in degrees cent. over sheath attained with watts in table III.

C. Temperature rise of conductor in degrees cent. over temperature of cable surroundings, conductor rise and sheath rise attained with watts in table III.

cables and thus these tables are more strictly a result of mathematical calculation than are tables I to IV, but some direct experimental data on two-conductor forms are available so it is known that the calculated values are in line with actual practical values.

Approximate carrying capacity of cables of any number of conductors may be calculated from the rule that the total carrying capacity of all the conductors in a cable is approximately the same for any number of conductors. Actually this aggregate carrying capacity increases slightly as the number of conductors increases. Thus a two-conductor cable has about 8 per cent more and a four-conductor 8 per cent less "total cable temperature rise" than a three-conductor cable of the same total copper area and carrying the same aggregate current. Thus to determine the temperature rise for a given current per conductor for a cable of any number of conductors n greater than three we may safely proceed as follows. Determine the rise for a three-conductor cable of the same aggregate area and for a current per conductor of $3/n$ times the given value, and diminish this rise by 8 per cent of the "total cable rise" (that is exclusive of duct rise). Though these data apply to the total cable rise the sheath and insulation rises have quite different relative values for the different number of conductors.

TABLE VI

FLAT DUPLEX CABLES.

A—Temperature rise of conductor above sheath in degrees centigrade produced by 2/3 of the watts in table I, *i. e.*, the same current per conductor.

B—Temperature rise of sheath above cable surroundings in degrees centigrade produced by 2/3 of the watts in table I, *i. e.*, the same current per conductor.

Type "H" Three-Conductor Cable. Table VII gives data for the type of cable proposed by Hochstadter and commonly called Hochstadter or type "H" cable. We are here concerned only with the three-conductor form. This consists of a cable in which all the insulation is placed on the conductors and which has a relatively thin covering of metal placed over the insulation on each conductor. This construction is used primarily for the purpose of elimination of electrical stresses in the electrically weak filler spaces. However, we are herein concerned only with the incidental though important effect of the metal covering or foil on carrying capacity. The metal covering as usually used brings the temperature of the entire surface of the insulation of each conductor nearly to the temperature of the sheath and thereby greatly reduces the temperature difference between conductor and sheath.

Table VII shows directly the maximum effect which can be gained by this construction, that is, on the basis of perfect thermal conductance of the foil but may be used as indicated below for convenient approximate calculation of temperature rise for practical conditions. Thus the temperature difference for the theoretically perfect condition may be found from Table VII and the temperature difference which would exist if the metal were not present may be calculated from methods described above. A known or assumed "efficiency" of the foil will then allow determination of the temperature for the practical condition. Thus for example consider 350,000-cm. conductor with 10/32-in. paper insulation. For 252 amperes, as given in Table I, the temperature difference given in table VII between conductor and sheath is 7.0 degrees. From table II, we find by interpolation, the temperature difference for that size of conductor and for a thickness of insulation of 10/32 in. between conductor and sheath (5 plus 5/32) to be 13.7 degrees. If we assume an effective thermal efficiency for the foil of 75 per cent, the temperature difference is found to be 7 plus $0.25 \times 6.7 = 8.7$ degrees. Actually, with practical cables the "effective thermal efficiency" of the foil is considerably greater than 75 per cent. Hence, in the absence of specific data it will usually be on the safe side to figure on that value.

TABLE VII.

THREE-CONDUCTOR HOCHSTADTER CABLES

A—Temperature rise of conductor above sheath in degrees centigrade produced by the watts in table 1.

B—Temperature rise of sheath above cable surroundings in degrees centigrade produced by the watts in table I.

750,000	3.0	14.6	4.5	13.4	5.6	12.5	6.8	11.4		

Column A gives the temperature rise of conductor above sheath temperature that would be produced by the watts from table I on the assumption that the foil has infinite thermal conductance.

Concentric Cables. The combined carrying capacity of the conductor of concentric cables is nearly the same as for a single-conductor cable having the same total copper area and the same total insulation thickness. This is based on the assumption of equal current density in the different conductors. For more exact calculation the total "cable rise" found by the above rule should be multiplied by the following factors which are nearly independent of the size of conductor. (These factors apply to two-conductor concentric cables).

Insulation between conductors	3/32	4/32	5/32	6/32	8/32
Multiplying factor for total cable rise	0.97	0.96	0.95	0.94	0.92

Rope-Core Cables. The watts necessary to give a certain temperature rise of "hollow" or rope-core cables may be taken the same as for a solid conductor cable

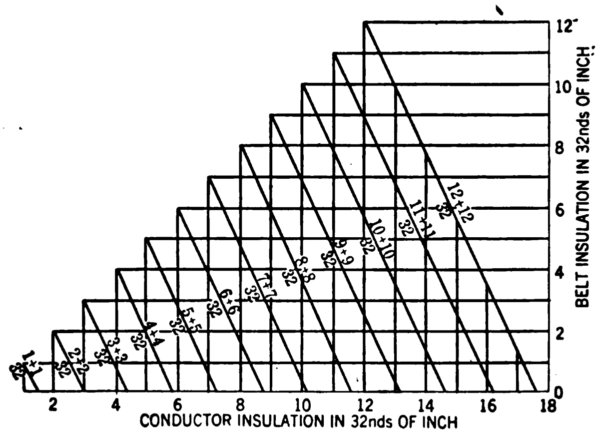

Fig. 2

having the same outside conductor diameter. The carrying capacity will then be proportional to the square root of the amount of copper in the conductor.

APPENDIX

The temperature of free air during the summer months may be as high as 40 deg. cent. Where the temperature of the air is not known this figure may be assumed as the base temperature in making calculations. If the cable is subjected to the direct rays of the sun, then 50 deg. cent. may be the figure used.

The base temperature of cables installed in the earth usually may be taken as 20 deg. cent. This is approximately the maximum temperature that the earth at conduit attains in this latitude. The base temperature of submarine cables is usually taken as 20 deg. cent.

Example No. 1. A three-conductor 350,000-cir. mil 6/32-in. plus 6/32-in. paper-insulated lead-covered cable is operating at 13.2 kv. It is freely suspended in air at an ambient temperature of 40 deg. cent. What is the allowable carrying capacity?

Allowable operating temperature (A. I. E. E.) 85 deg. cent. – 13.2 deg. cent. = 71.8 deg. cent.

Allowable cable rise 71.8 deg. cent. – 40 deg. cent. (Base Temp.) = 31.8 deg. cent.

From table I—6.75 watts (252 amperes) gives 25 deg. cent. cable rise for a 350,000-cir. mil cable insulated with 3/32-in. plus 3/32-in. paper.

From table II, the rises produced by 6.75 watts on a 350,000-cir. mil 6/32-in. plus 6/32-in. paper cable are:

Insulation rise.................. 15.2 deg. cent.
Sheath rise..................... 11.6 deg. cent.
Total cable rise produced by
6.75 watts.................. 26.8 deg. cent.

To produce 31.8 deg. cent rise would require $6.75 \times \frac{31.8}{26.8}$ watts.

The current to produce these watts as I^2R loss

$252 \times \sqrt{\frac{31.8}{26.8}}$ = The allowable carrying capacity = 274 amperes.

Example No. 2. What change in calculation would be necessary had the insulation been 8/32-in. plus 2/32-in.? The cable to operate at the same voltage.

See paragraph on unequal belt and conductor insulation. The insulation rise is the same as for a 5/32-in. plus 5/32-in. cable or........ 13.7 deg. cent.

The lead rise is the same as for a 6/32-in. plus 6/32-in. cable or........ 11.6 deg. cent.

The total cable rise is............. 25.3 deg. cent.

The allowable carrying capacity is

$252 \times \sqrt{\frac{31.8}{25.3}}$ .... 283 amperes

Example No. 3. What will be the carrying capacity of four three-conductor No. 0000 – 6/32-in. plus 6/32-in. V. C. cables to be installed in a conduit system containing no other cables? The cables operate at 15 kv.

Allowable operating temperature (A. I. E. E.) 75 deg. cent. – 15 deg. cent. = 60 deg. cent.

Maximum allowable rise of cable and conduit assuming 20 deg. cent. normal earth temperature = (60 deg. – 20 deg.) =..................... 40 deg. cent.

From table I—5.80 watts—(179 amperes) give 25 deg. cent. rise for No. 0000 – 3/32-in. plus 3/32-in. cable.

Table II gives 5.80 watts—(179 amperes) produce 15.0 deg. + 11.3 deg. =.......................... 26.3 deg. cent.

The total watts to be dissipated at this current equal 4 × 5.80 =....... 23.2

Assuming a heating constant of 1.0, the duct rise is 23.2 × 1.0 =....... 23.2 deg. cent.

One hundred seventy-nine (179)

amperes per conductor gives a total rise (cable and duct) 26.3 + 23.2 = . 49.5 deg. cent.

The carrying capacity for 40 deg. cent. rise (allowable rise) =

$$179 \times \sqrt{\frac{40}{49.5}} = \ldots\ldots\ldots\ldots\ldots\ldots \quad 161 \text{ amperes}$$

Example No. 4. Six three-conductor No. 0 – 4/32-in. plus 4/32-in. paper-insulated cables are operating in a conduit system. The cables operate at 2.3 kv. Measurement of the duct wall temperatures gives 45 deg. cent. The cables each carry 120 amperes per conductor. Is this a safe load?

The allowable operating temperature (A. I. E. E.) 85 deg. cent. – 2.3 deg. cent. = ... 82.7 deg. cent.

From tables I and II, 115 amperes give (12 + 12.9)

$$= 24.9 \text{ deg. cent. } 120 \text{ amperes give } \frac{120^2}{115^2} \times 24.9$$

= 27.0 deg. cent. cable rise. (27.0 deg. cent. + 45 deg. cent.) = 71.0 deg. cent is the temperature at which cables are operating with 120 amperes per conductor.

The cables are capable of carrying

$$120 \times \sqrt{\frac{\text{allowable rise}}{\text{rise produced by 120 amps.}}}$$

$$= 120 \times \sqrt{\frac{82.7 \text{ deg. cent.} - 20 \text{ deg. cent.}}{72.0 \text{ deg. cent.} - 20 \text{ deg. cent.}}}$$

= 132 amperes.

Example No. 5. Same as No. 3 except dielectric losses at 60 deg. cent. are known to be 0.26 watts per foot.

The total rise produced by 5.80 watts per foot = 49.5 (From problem No. 3).

$$\text{The rise produced by } 0.26 \text{ watts} = 49.5 \times \frac{0.26}{5.8}$$

= 2.2 deg. cent.

This allows 40 – 2.2 = 37.8 deg. cent. as rise to be produced by $I^2 R$ loss.

$$\text{The carrying capacity} = 179 \times \sqrt{\frac{37.8}{49.5}}$$

= 156 amperes.

The Chart. The chart given here is really the solution of problems in the same class as Example No. 3, *i. e.*, the solution of carrying capacity problems of paper and V. C. cables installed in conduits where no measurement of duct wall temperature is made. The chart will give results about as accurately as calculation from the tables.

The method of using the chart is as follows: In the upper right hand find the intersection of the size of conductor and insulation thickness. From the point of intersection follow a horizontal line to the upper left-hand corner of the chart to the line giving the factor "number of cables times duct (heating) constant."

From the intersection of these lines follow the vertical line to the intersection with the lines marked "allowable temperature rise." This is the allowable operating temperature minus the normal earth temperature.

Next follow a horizontal line to the intersection of the lines marked number of cables times duct (heating) constant.

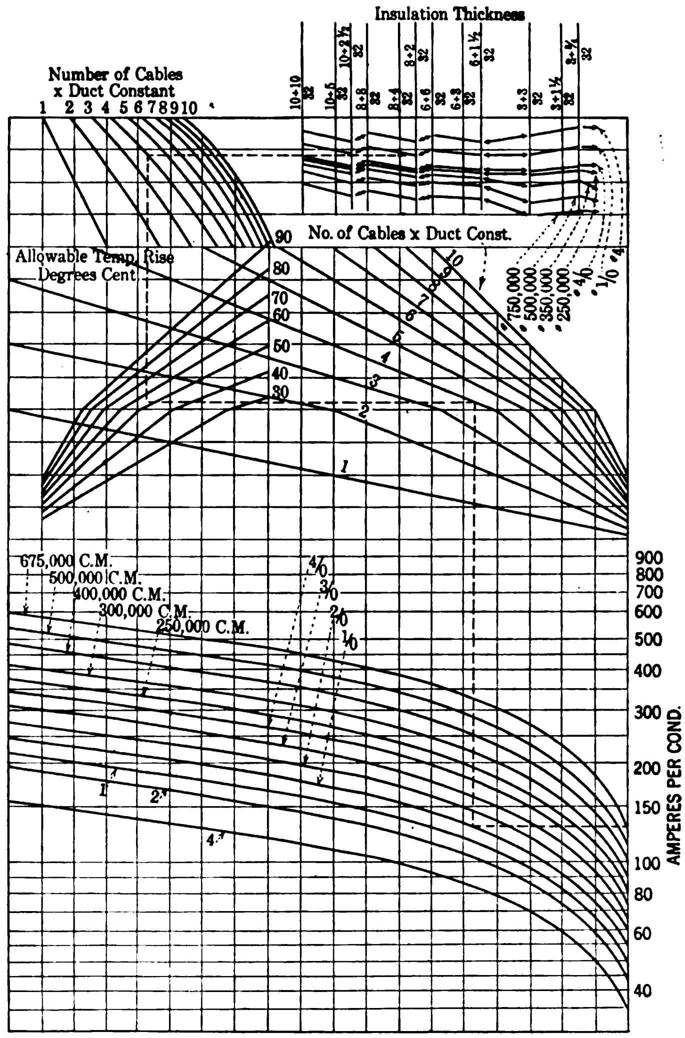

Fig. 3—Current-Carrying Capacity of Three-Conductor Underground Cables
Round and Sector, Paper and Varnished Cloth

Follow a vertical line down to the intersection with the size of conductor. Directly opposite this will be found the amperes per conductor.

Acknowledgments

The author wishes to express his appreciation to Mr. H. W. Fisher and Mr. C. W. Davis for valuable suggestions in the preparation of this article, and to Mr. A. M. Hagen who has taken an active and interested part in calculating the tables and in preparation of manuscript.

CORRESPONDENCE

TERMINOLOGY IN REGARD TO REACTIVE COMPONENT

To the Editor:

Recently a great deal has been written and spoken concerning power factor and allied subjects. The A. I. E. E., various commercial engineering societies, the technical press and individual organizations have devoted much attention to these subjects.

In following this discussion one cannot but be impressed by the wide variance in terminology, particularly when the reactive component of the kv-a. is involved. The following is a list of terms which the writer has happened upon in recent papers read before the A. I. E. E. and in recent numbers of the *Electrical World*.

Referring to the Reactive Component:

Reactive volt-amperes.
Reactive power.
Wattless power.
Imaginary power.
Apparent reactive power.
Reactive kilowatts.
Reactive kilowatt-hours.
Kilo-reactive-watt-hours.
Reactive kilovolt-ampere-hours.

Referring to Volt-Amperes or Volt-Ampere-Hours:

Apparent power.
Apparent energy.
Kilovolt amperes.
Total vector watt-hours.
Kilovolt-ampere-hours.

Definition 24 of the Standardization Rules of the A. I. E. E. defines "Reactive Volt-Amperes". The term "reactive power" is not used in the rules. In the recent report of the Special Joint Committee on the Determination of Power Factor in Polyphase Circuits and the accompanying papers, the expression "reactive power" was used much more frequently than "reactive volt-amperes". This term is consistent with and completes what might be called the "power triangle", of which apparent power is the hypotenuse, true power is the base, and reactive power is the altitude. Furthermore, from a theoretical point of view "reactive power" may be justified by an analysis of its physical significance as the rate at which energy is stored in or released from the magnetic field, although its measurement by the "reactive volt-ammeter" will be only approximate, except when the voltage and current are sinusoidal and the circuit constants do not vary cyclically (see article on " Reactive Power and Unbalanced Circuits" by Prof. Waldo V. Lyon, *Electrical World*, June 19, 1920, page 1417).

When the terminology is extended, and it becomes necessary to use a unit involving time, the expression "reactive kilowatt-hours" seems to the writer to be a misnomer. Also a unit should be definite and clearly understood, without any modifying adjectives.

More and more power companies are adopting power factor rates necessitating the use of integrating meters which record the reactive component kv-a. hours. Various companies have recently issued rate schedules in which the expressions "reactive kilowatt-hours", "kilo-reactive-watt-hours" (abbreviated k. r. w-hr.) etc., are used. Standardization of terms is much needed.

The writer would point out the desirability of coining or adopting an entirely new term for the reactive volt-amperes. A simple word with a single letter abbreviation would greatly simplify the present involved terminology. For illustration suppose we use the word "Blank", abbreviated "b", for the unit for expressing reactive power. The so-called power triangle will then have kv-a. for the hypotenuse, kw. for the base and "kb." for the altitude. "Kb-hr." then corresponds to "kw-hr.", and a meter which integrates the reactive component of the kilovolt-amperes then becomes simply a "blank-hour" meter, corresponding to a watt-hour meter.

The difficulties involved in defining and measuring such a unit are no greater than, and in fact are involved in and in a sense precede, the difficulties of defining and measuring power factor.

In view of these facts it seems highly desirable that the Standards Committee of the A. I. E. E., perhaps in conjunction with the N. E. L. A., or the Special Power Factor Committee, should select and define suitable terms for these conceptions.

RALPH L. THOMAS
Pennsylvania Water & Power Co., Baltimore.

A-C. VERSUS D-C. ARC WELDING

To the Editor:

With reference to the correspondence appearing on page 647 of the July JOURNAL, I wish to say that I personally am opposed to becoming a party to purely commercialized arguments, and for this reason, I will not mention the name of the company which manufactured the arc welding transformers submitted to us for test purposes, but will simply outline certain test data obtained thereon:

Primary			Secondary			Transformer	
Volts	Amp.	Kw.	Volts	Amp.	Kw.	Efficiency	Power Factor
437	39.2	3.6	20	112	2.24	62.5%	21.0%
436	44.4	4.96	20	128	2.56	51.5%	25.6%
440	49.5	5.56	21	150	3.16	56.5%	25.6%
396	48.0	5.85	20	170	3.47	59.5%	30.8%

The above data were obtained when the operator was using standard welding wire having a light coating throughout its entire length on approximately one-half of its surface.

Although the power factor of the arc itself is approximately 88 to 92 per cent, according to good authorities, nevertheless the power factor of the welding trans-

former in which we are actually interested is much below this value as indicated by the above table. This does not mean that the transformer is poorly designed but is simply a recognition of the fact that this characteristic must be incorporated if the transformer is to be satisfactory for lightly coated metallic electrode welding.

Based upon the *no load losses* in addition to the above obtained data, and also including the cost of the partially coated electrode material, the operating cost data, including power, wire and labor were prepared as presented in my paper.

Some individuals evidently fail to realize that the cost of welding wire is even more important than the cost of power in determining the operating cost of arc welding, due to the fact that the efficiency of the transformer is practically on a par with that of the overall efficiency of a modern single-operator inherently regulating motor-generator set, whereas the power factor of the transformer is materially below that of a modern induction motor used as part of the interconnected single-operator outfit. For example, under normal full load conditions, the power factor of the induction motor will be approximately 90 per cent, whereas the no load power factor, namely when the motor-generator set is running light, will be approximately 48 per cent. If the welding operator uses power 65 per cent of the time, it is easy to calculate that the average all day power factor is approximately 75 per cent, whereas if the operator works 80 per cent of the time, the average all day power factor is approximately 81½ per cent, al of which (including no load power factor) are apprecil ably above the tabulated test data for the a-c. welding transformer.

I would refer those who are interested in a further discussion of the power factor of the a-c. transformer to an article on page 233 of the *Electrical World* for February 1, 1919.

Westinghouse Elec. & Mfg. Co

NOTE ON SPEED OF FLASHING OF INCANDESCENT SIGNAL LAMPS

A portion of a study of the theory of signaling units involving incandescent lamps, which was undertaken in response to a request from the National Research Council and the U. S. Signal Corps for the development of a unit for use in daylight signaling is herein given.

Filament Characteristics Involved. Various factors involving speed where the telegraphic dot and dash signals are produced by the flashing of an incandescent lamp, are discussed in a broad way in a contrast of tungsten with carbon for filament material. Most important are (1) the change in resistance with change in temperature, (2) the quantity of energy required to heat the filament through a given temperature range, (3) the total emissive power of the filament material, (4) the maximum temperature of a flash, and (5) the efficiency of the radiation in producing vision. For lamps of equal voltage, life and luminous flux, tungsten is favored during the heating portion of a flash by a factor of six or seven.

Observed Speeds and Their Comparison with Expected Values. A photometric method of studying the performance of lamps on flashing is described and the results obtained with various lamps are presented. These are compared with computed values based on steady current measurements and the supposition that a lamp filament on heating or cooling passes through a succession of steady states. The agreement is quite satisfactory, when there is excepted the case of a filament immersed in hydrogen, where the discrepancy may be ascribed to ionization effects.

Speed Functions. It is further shown that a simple function involving only steady current measurements of wattage, resistance and temperature in the neighborhood of the maximum temperature of a flash, together with the thermal capacity of the filament, will serve quite accurately in rating various lamps as to their flashing speeds.

Some Fundamental Generalizations.

(1) The time required for a filament to heat to approximately its maximum brightness exceeds greatly the time required in cooling to effectively zero brightness.

(2) The higher the maximum temperature of a flash, the greater is the speed of the flash.

(3) The smaller the filament, the greater is the speed of the flash.

(4) The less the resistance in a circuit external to the flashing lamp, the greater is the speed of the flash.

(5) The speed of flashing for a given filament at a given temperature in various atmospheres—including in vacuo—is the greater, the greater the gas loss.

(6) For lamps of the same open filament construction in various atmospheres, such that they possess the same luminous flux and the same average life at the same fixed voltage, the speed of flashing is the greater, the greater the gas loss.

Ribbon Versus Wire Filaments. A contrast of a lamp containing a ribbon filament in argon as proposed by the Nela Research Laboratory in response to the request noted above, with that lamp which was its nearest competitor indicated speeds and efficiencies in favor of the former lamp of the order respectively of 1.6 and 1.25.—A. G. Worthing, in *Journal* of the Franklin Institute.

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

FUTURE INSTITUTE MEETINGS

OCTOBER MEETING

The first regular Fall meeting of the Institute will be held in Philadelphia October 8, 1920. The tentative program, to which some additions will probably be made, includes an afternoon and an evening session, with an informal subscription dinner between the sessions.

Two papers will be presented at the afternoon session, as follows:

Economic Study of Secondary Distribution, by P. O. Reyneau and H. P. Seelye, Detroit Edison Co.

Electrical Demand Measurements, by P. A. Borden, Ontario Power Commission.

The evening session will be a special meeting to commemorate the hundredth anniversary of the discoveries of Arago, Ampere, Davy, and Oersted. The principal speakers will be Prof. Elihu Thomson and Prof. M. I. Pupin. Demonstration of some of the original experiments will be made. Addresses by other speakers will be announced later.

NOVEMBER MEETING

The November meeting will be held in Chicago on November 12, 1920, and will be under the auspices of the Protective Devices Committee. The principal paper of the meeting will be by Mr. D. W. Roper, Chairman of the Committee, on the subject of Lightning Protection.

A. I. E. E. DIRECTORS MEETING

AUGUST 12, 1920

The first meeting of the Board of Directors of the American Institute of Electrical Engineers for the administrative year beginning August 1, 1920, was held at Institute headquarters, New York, on Thursday, August 12, 1920 at 3:00 p. m.

There were present: President A. W. Berresford, Milwaukee; Past Presidents Calvert Townley and C. A. Adams, New York; Vice-Presidents Charles S. Ruffner, New York, Charles Robbins, Pittsburgh, L. T. Robinson, C. S. McDowell, Schenectady, E. H. Martindale, Cleveland; Managers, Wm. A. Del Mar, W. I. Slichter, L. E. Imlay, E. B. Craft, New York, Wilfred Sykes, F. D. Newbury, Pittsburgh, G. Faccioli, Pittsfield, H. B. Smith, Worcester; Treasurer, George A. Hamilton, Elizabeth, N. J.; H. E. Farrer, representing Secretary F. L. Hutchinson, New York.

Resolutions were adopted authorizing the appointment of a new standing committee, on "Coordination of Institute Activities," to replace the former Board's Committee on Technical Activities, which was authorized by the Board of Directors May 17, 1918, for the purpose of stimulating and coordinating the activities of technical committees; the new committee to fill a need for a committee of much broader scope, on coordination of Institute activities in general, to which might be referred, for recommendation to the Board, questions of Institute procedure and policy.

President Berresford announced the appointment of committees for the administrative year commencing August 1, 1920, as published elsewhere in this issue of the JOURNAL.

In accordance with the by-laws of the Edison Medal Committee, the Board elected from its own membership Messrs. W. I. Slichter, L. E. Imlay, and F. D. Newbury, to serve upon the Committee for the term of two years ending July 31, 1922.

The following Local Honorary Secretaries, whose terms expired July 31, 1920, were reappointed by the Board for the term of two years ending July 31, 1922: L. A. Herdt, Canada; A. S. Garfield, France; Harry P. Gibbs, India; T. P. Strickland, New South Wales; Robert J. Scott, New Zealand; W. G. T. Goodman, South Australia; John W. Kirkland, South Africa.

The action of the Finance Committee in approving monthly bills amounting to $21,592.40 was confirmed.

Reports were presented of meetings of the Board of Examiners held on July 26 and August 9, 1920; and the actions taken on applications at those meetings were approved. Upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 28 Students were ordered enrolled; 173 applicants were elected to the grade of Associate; 11 applicants were elected to the grade of Member; 1 applicant was elected to the grade of Fellow; 33 applicants were transferred to the grade of Member; 6 applicants were transferred to the grade of Fellow.

The Board authorized the formation of an Institute Section at Akron, Ohio, subject to the approval of the Sections Committee.

Resolutions were adopted accepting an invitation to become a Charter Member of The Federated American Engineering Societies and to appoint delegates to the first meeting of the American Engineering Council, to be held during the Fall of this year. These resolutions appear elsewhere in this issue of the JOURNAL.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

SIXTH NATIONAL CHEMICAL EXPOSITION

The Sixth National Exposition of Chemical Industries will be held in Grand Central Palace, New York City, Sept. 20 to Sept. 25, inclusive. The program that has been arranged is in keeping with the progress of the industry, which is evidenced

by more than 400 different exhibits securing space this year. The program calls for five symposiums, for which the speakers are among the best known in the industrial and chemical engineering worlds. The symposiums will be on Fuel Economy, Industrial Management, Materials Handling, Chemical Engineering, and Ceramics. Motion pictures also will greatly aid in placing the importance of the chemical industry before the public.

Dr. Charles H. Herty, chairman of the Advisory Committee of the exposition, will open the display at 8 o'clock on the evening of Monday, Sept. 20. Charles L. Reese, who will talk on "Cooperation in the Industries," and other speakers will follow. The motion picture program for the opening night includes two subjects, "The U. S. Ammonium Nitrate Plant No. 2 at Muscle Shoals," by courtesy of Dwight P. Robinson & Co., and "Modern Packaging Methods," by courtesy of the Pneumatic Scale Corporation. Beginning Tuesday, afternoon and evening sessions will be held in order to carry out the big program.

I. E. S. CONVENTION AT CLEVELAND

As has already been announced, the date for the next annual convention of the Illuminating Engineering Society, originally set for September 27-30, has been changed to October 4-7. The change was made to avoid conflict with the American Legion Convention to be held in Cleveland the last week in September it being felt that the gathering together, in one city and at the same time, of the two organizations, would cause Cleveland's visitors to suffer inconveniences.

It is the aim of the committee to make this convention carry a popular appeal not only to technical men but to all those in any way interested in illumination.

The committee in charge of arrangements is as follows: General Convention Committee, J. E. North, Cleveland Electric Illuminating Company, chairman, W. M. Skiff, National Lamp Works, vice-chairman; Reception Committee, G. E. Miller, Cleveland Illuminating Co., chairman; Publicity Committee, H. S. Greene, National Carbon Co., chairman; Entertainment Committee, J. M. Smith, Ivanhoe-Regent Works, chairman; Finance Committee, George S. Milner Erner Electric Co., chairman; Hotel Committee, A. M. Collins, Western Electric Co., chairman; Attendance Committee, G. S. Black, Cleveland Engineering Society, chairman; Registration Committee, J. L. Wolf, Builders Exchange, chairman.

CHICAGO SECTION OF AMERICAN WELDING SOCIETY ORGANIZED

At a meeting of members of the welding trade in Chicago, held in the rooms of the Western Society of Engineers, on Tuesday Evening, August 3rd, a Chicago Section of the American Welding Society was organized. There were about seventy-five in attendance, representing many railroads terminating in Chicago and also many of the larger local industries.

Election was held of officers and directors. Meetings will be held on the second Tuesday of each month in the rooms of the Western Society of Engineers, and those interested in the subject of Aurogenous welding, by all methods, are invited to attend. The Secy-Treas. is L. B. Mackenzie, 608 S. Dearborn St., Chicago.

HYDROELECTRIC DEVELOPMENT IN CEYLON

The proposed electrification of the industries of the island of Ceylon, and a partial transformation of the transportation systems from steam to electricity, offer a large opportunity in hydroelectric development today. The proposed scheme, developed by the Public Works Department, has been under consideration for a number of years past. Definite action was delayed because of the war, but it is expected now that arrangements will go forward rapidly for the early initiation of the work proposed. Recently at the request of the Ceylon Government Mr. J. W. Meares, the Electrical Advisor to the Government of India, made extensive investigations of the island's hydroelectric resources. Ceylon newspapers printed the gist of his report in various articles, a few extracts from which follow:

The report of Mr. J. W. Meares, M. Inst. C. E., M. I. E. E., Electrical Advisor to the Government of India, who was lent to Ceylon to report on our own hydroelectric schemes, has been published by the Government of India, Calcutta, and from it we place the following information before the reader. The report is on the Laxapana-Aberdeen project only.

The first part of this report gives general data regarding the available water in the area, *the possibilities of storage*, the order in which the four successive stages of development should be undertaken, and the power available.

The second part deals with the layout of the combined scheme calling attention to a number of points which must be borne in mind when designing it in detail.

The third part deals with the initial development of the scheme and touches upon the question of the subsequent extensions.

The fourth part goes into the utilization and price of the power, which are the prime factors in deciding if it shall be undertaken.

The fifth part deals on broad lines with the agency for carrying out the project.

It may be stated here that Ceylon has far *more water power than it can ever use* unless industries are specially started to turn this natural wealth into hard cash. The industries report gives outline figures showing some 264,000 hydroelectric horse power continuously available, and with additional storages not examined this would doubtless be considerably increased. Some of these sites were visited by the writer, and others were examined from the very excellent contour maps of Ceylon she is fortunate in possessing. Thus the Kotwalia Oya (a tributary of the Mahaveli Ganga) could be developed either at the St. Clair Falls, Talawakelle, where a flow of some 250 cusecs(cubic feet per second) and a fall of 800 feet would give over 16,000 e. h. p. continuously; or near Somerset, Gampola, where some 500 cusecs are always available with a fall of over 500 feet giving a further 20,000 e. h. p. and over. This last project is a meritorious one and was visited; but its possibilities are only a fraction of those of Laxapana-Aberdeen while the cost of development would be higher.

. . . . it (Laxapana-Aberdeen project) is an exceptionally favorable one in all the essential points, in that a large constant flow is assured, storage can be provided, two separate rivers can be combined, a large head is available, the locality is accessible and healthful, and the transmission distances are reasonable.

. . . . Briefly the project involves the harnessing of the Kenelgomu Oya and the Maskeliya Oya above their junction, by leading their waters in channels to a point where a fall of not far short of 2,000 feet can be obtained, and then by means of pipes leading this supply to Pelton wheels at the foot of the fall. The water that would ordinarily run to waste will be impounded in reservoirs above the off-take.

The Laxapana-Aberdeen project is recommended—

The continuous (24 hour) power available is—

First stage	20,000 e. h. p.
Second stage	37,000 e. h. p.
Third stage	64,000 e. h. p.
Fourth stage	96,000 e. h. p.

or 620 million units per annum.

The working head is over 1900 feet.

To get ultimate economy the scheme must be designed for the full development; and certain parts such as the channels must be built for the complete "first stage."

Statistics of power now used are quoted and the probable requirements for the tea industry and the *electrification of suburban railways* are estimated. The probable average cost per unit generated at the power house is found to be well under two cents initially and will be far lower hereafter.

Suggestions are made as to the rates at which power can be sold for various places and industries so as to give a reasonable return on capital. Recommendations are made as to the purchase of existing installations and as to the method of carrying out the Laxapana-Aberdeen project and working it thereafter.

The adoption of British Standard pressures and frequencies and, if possible, British plant, is urged.

The chief industry of Ceylon is agriculture—tea, coconuts, rubber, cinnamon, tobacco, coffee, and cinchona are the principal products. The island is one of the greatest tea-producing countries in the world, and tea plantations make up the most prominent feature of the island now. To make way for them most of the forests of rare and valuable trees are being destroyed. Ceylon has long been noted for being a garden place of the world, with a great variety of ferns and flowers remarkable for their beauty.

Mr. Meares' report gives the following estimate as to the total requirements of the tea industry:

The annual output of Ceylon tea is 200,000,000 lb. . . . power for driving the machinery requires 0.25 units per lb. of tea which comes to 58,000,000 units. Manufactories, however, will continue to use their own water power so that the actual requirements may be given as 30,000,000 units. If used for 3650 hours per annum ten hours a day, this means a rate of 8200 kilowatts at the factories or about 10,000 kilowatts more or less at the power station eventually. The "peak load" would be somewhat higher but not much. For drying purposes 200,000,000 pounds at 1.67 units per lb. comes to some 330,000,000 units as a maximum. One may reasonably look forward to 150,000,000 units being used within a reasonable time. If used for 2900 hours per annum, (eight hours a day) this means a rate of 51,600 kilowatts at the factories or say 60,000 kilowatts at the power station. A favorable factor is that the load, being largely non-inductive, would have a good power factor. Combining this, the total in sight comes to 180,000,000 units and 70,000 kilowatts installed to meet it. The load factor of the tea industry comes then to 34 per cent only.

Mining is another industry of Ceylon. The island is famed for its precious stones, especially rubies and sapphires. Plumbago mines are also of note.

Colombo, the capital of Ceylon (213,396—population in 1911) will probably be the center of electrification projects. Suburban railways, and transmission lines to factories and power plants, will be in the electrification scheme. The electrification of all the island's railroads is not planned, however.

The electrification of the main lines of Ceylon is out of the question as a commercial proposition. Electrification will only pay for the steep ghat section and suburban traffic. The latter covers the coastline to Panadura, the line to Negombo and the Kelani Valley line.

For domestic use in Colombo and other cities the transmitted power will also be of great value. The report advises that the whole problem of water-borne sewage would be simplified, with great saving, by the use of motor-driven, centrifugal sewage pumps; and that suburban traffic could be eased by the extension of electric tramways.

The whole island is within the use of transmission distance of the Laxapana-Aberdeen scheme, but at present the demand is great enough only in the Western and Central Provinces to justify the cost of transmission. Development within the demand, however, will be well worth while; and after completion of the main electrification project expansion can take place as required.

ENGINEERING FOUNDATION

A NEW FORM OF WEIR

A new form of weir and a simple, straight-line formula have been devised by Clemens Herschel, Past-President, Am. Soc. C. E., for gaging the flow of water in open channels. This weir and the accompanying formula are results of experiments made by Mr. Herschel with the support of Engineering Foundation, at the laboratory of Massachusetts Institute of Technology. A report of the experiments was presented in the form of a paper to the American Society of Mechanical Engineers. and was printed in full in "Mechanical Engineering" for February, 1920, the Journal of the American Society of Mechanical Engineers. See also *Engineering News-Records*, issue of April 8, 1920, pages 710-712. The complete paper has been issued as Number 4 in the "Reprint" series of Engineering Foundation. Copies can be had by members on application to office of Engineering Foundation; non-members may obtain copies at the rate of 35 cents each.

COMMITTEE ON HYDRAULIC RESEARCH

A committee on Hydraulic Research has been appointed by Engineering Foundation. The committee will endeavor to formulate problems to which it may be possible for Engineering Foundation to devote some of its efforts. It will also endeavor to collect information about existing hydraulic laboratories and other places in which hydraulic experiments can be conducted. Mr. J. Waldo Smith and Mr. Silas H. Woodard have consented to serve as the committee. Members of the Board are requested to assist with suggestions and information.

FEDERATED AMERICAN ENGINEERING SOCIETIES

ADDITIONAL SOCIETY RATIFICATIONS

At the meeting of the Board of Directors of the American Institute of Electrical Engineers held in New York on August 12, 1920, the following resolutions to become a charter member of The Federated American Engineering Societies were unanimously adopted;

WHEREAS, under date of July 26, 1920, the Joint Conference Committee of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, acting as the Ad Interim Committee in accordance with the authorization of the Organizing Conference held in Washington, D. C., June 3-4, 1920, extended to the American Institute of Electrical Engineers an invitation to become a Charter Member of the Federated American Engineering Societies, and to appoint delegates to the first meeting of the American Engineering Council; and

WHEREAS, the American Institute of Electrical Engineers recognizes the pressing necessity for such an organization, is in full accord with its objects, and approves of the theory of the proposed organization and the method by which it is to be constituted, be it

RESOLVED: That the American Institute of Electrical Engineers accepts the invitation extended to it to become a Charter Member of the Federated American Engineering Societies, and pledges its hearty cooperation in the work thereof; and further be it

RESOLVED: That the President be instructed to present to the Board of Directors at its October meeting a suggested list of delegates to the first meeting of the American Engineering Council, which is proposed to be held during the Fall of the present year.

REPRESENTATION OF LOCAL ORGANIZATIONS

In the August JOURNAL, the Joint Conference Committee interpreted the Constitution and By-Laws concerning the relation between local and state affiliations as regards membership in The Federated American Engineering Societies. The Committee is in receipt of communications relative to the interpretation of the Constitution and By-Laws as they apply

solely to the membership of local engineering and allied technical organizations in The Federated American Engineering Societies.

It is contended that a local affiliation could not claim representation on the basis of its members who belong to the national societies that had joined the organization directly, and would not be required to pay dues on that account. The Constitution states in Article IV—Section 3

provided that in the determination of the representation of local, state and regional organizations and affiliations no count shall be taken of any organization which is represented individually or through another local, state or regional organization or affiliation;

That is to say, if there were in a community five local engineering and allied technical organizations all in a local affiliation, and one of them was a member of The Federated American Engineering Societies, then the remaining four societies would be entitled to representation as an affiliation in The Federated American Engineering Societies, through its membership as a local affiliation, on the basis of the aggregate membership—less the membership of the local organization that already held membership in The Federated American Engineering Societies, or each of the four organizations could individually become a member of The Federated American Engineering Societies.

THE LARGEST AMERICAN ENGINEERING ORGANIZATION

It is a common failing to refer to The Federated American Engineering Societies as a "proposed" organization. Attention is called to the fact that The Federated American Engineering Societies is in actual existence and at present its membership consists of The American Society of Mechanical Engineers, the Detroit Engineering Society, the Technical Club of Dallas and the American Institute of Electrical Engineers. It is not a question whether the organization will be formed; the Federated American Engineering Societies already is the largest engineering organization in this country.

MEMBERSHIP REQUIREMENTS

There still seems to be uncertainty in the minds of some as to the eligibility of organizations for membership. The following provision is in Chapter I, Section I of the By-Laws of The Federated American Engineering Societies:

Any society or organization of the engineering or allied technical professions whose chief object is the advancement of the knowledge and practise of engineering or the application of allied science, and which is not organized for commercial purposes, is eligible for membership.

This provision is in no sense intended to make the organization exclusive, but merely to make it inclusive of all those engineers and allied technologists who are members of organizations not formed for commercial purposes and whose chief aim is the advancement of the knowledge and practise of engineering. The tendency of the times is to raise the standard of engineering requirements and this is augmented by the constantly increasing influence of the technical schools. The four Founder Societies have maintained high standards for membership and of late their requirements have been increased, and yet, in spite of this, these societies have shown an increasing growth in membership.

ADVANTAGE OF COMBINED PRESTIGE

The Federated American Engineering Societies will have the advantage of the combined prestige of all its Member-Societies and will, therefore, have a greater standing than any individual society. It was for the purpose of securing this advantage that the organization was made one of societies and not of individuals. An individual can only become connected with the work of the organization through his membership in a national, local, state or regional engineering or allied technical organization; since there are no individual memberships in The Federated American Engineering Societies, therefore, individuals must join these organizations in order to be identified with its work. The Federated American Engineering Societies will be a powerful, dominant organization. No engineering or allied technical organization can afford to reject the opportunity for affiliation; it is an obligation to the profession to be so affiliated.

ORGANIZATION IS REPRESENTATIVE AND DEMOCRATIC

The form of organization of The Federated American Engineering Societies is analogous to that of the Federal Government in which the individual citizen is represented first in the local government, then in the state, and finally in the national government; he does not have individual representation in the national government, but because he does not have this representation it cannot be construed that the organization is undemocratic.

It must be quite evident to any one who would start a new engineering organization, and it is the common belief that there are already too many in existence, that the organization would be without prestige, and, therefore, without the standing it would have with the prestige The Federated American Engineering Societies will possess. It is felt that the individual will be just as responsive through his local organization, and perhaps more so, than he would be if he held an individual membership. It is the experience of the national engineering societies that the individual engineer is much more responsive to the work of the society where it has local and professional sections than where there are no such sections. While The Federated American Engineering Societies is an organization of societies, this does not prevent the individual member of any of the Member-Soceities from communicating directly with the secretary or other executive officers of the organization. The governing body is controlled by the representatives of the Member-Societies; the district members of its Executive Board are elected by the votes of the representatives from each district.

Notwithstanding the vagueness of the word democracy, the Joint Conference is firmly of the opinion that The Federated American Engineering Societies is truly a democratic organization because it represents the individual engineer and allied technologist.

THE MINNESOTA FEDERATION

The movement to federate the engineer and the allied technologist is again to bear fruit. The Committee is gratified to observe that engineers and architects from all parts of the State of Minnesota met at Duluth recently and took the first steps toward the formation of a state federation of engineers and architects. It is presumed that this organization will become a member of The Federated American Engineering Societies and it is hoped that the action in Minnesota will be followed by similar action in other states; only through united action of this character can the full strength of the solidarity of the engineering and the allied technical professions be realized.

CURRENT ENGINEERING TOPICS

ORGANIZATION AND STATUS OF FEDERAL POWER COMMISSION

The Federal Power Commission which was created to administer the Water Power Act, which was passed and signed by the President in the closing days of the last Congress, has been organized along the following lines: engineering, accounting, statistical, regulatory, licensing, legal and operation. It is apparent that the engineering division will be the most important because it will make general investigation of the electric power industry, power sites, costs and development. This division will have to report the results of these examinations to Congress preparatory to construction by the U. S.; will prepare plans for the development of streams upon which appli-

cation for licenses are made; will consider construction plans proposed by licenses; will make physical valuation of property in rate-making proceedings, and when existing plants are brought under the Act it will determine the necessary repairs, maintenance charges, develop operating rules, and determine adequate depreciation reserves. All of this work will come under the immediate charge of Mr. O. C. Merrill, who will act as chief engineer.

The actual work of the Commission has been somewhat barred because the comptroller of the Treasury has ruled that under the terms of the act, there is no money available to pay the required personnel. This means that the personnel will have to be assigned to the Commission by the various Departments until such time as appropriations can be made to pay for the required assistance.

So far Lieut. Col. William Kelley of the Engineers Corps, has been assigned to the Commission as engineer officer and Major L. W. Call has been assigned from the Judge Advocate General's Office as chief counsel.

It was one of the chief duties of the new Commission to formulate regulations that would make the applications for water power privileges valid. These regulations were drawn up by the Secretary and all interested Government Departments and outside organizations were invited to send their representatives to a Washington conference on August 12th for the purpose of discussion in making further recommendations. This meeting was followed by another conference on the 13th with representatives of interested financial institutions, so that their recommendations could also be considered before the application was put into final form. It is contemplated that the application blanks in final form will be completed and ready for use early in September.

District offices of the Commission have been opened at St. Paul and St. Louis in the local offices of the Corps of Engineers. This is for the convenience of the applicants in the Middle West. Similar district offices have been opened in Denver and San Francisco in the legal offices of the Forest Service for the convenience of the Western applicants.

CHEMICAL WARFARE SERVICE

When the Army Reorganization Bill passed the last Congress, it provided for a separate Chemical Warfare Service. The transfer of General A. A. Fries and Colonel Earle J. Atkisson from the Corps of Engineers to the command of this Service has now been completed and they are in the process of building up their organization under the terms of the Act.

In order to bring the Service up to full strength there are something over twenty commissions that will have to be awarded this Fall. In an effort to arouse interest in securing these commissions the heads of twenty-five technical colleges have been apprised of the conditions, in the hope that some of their students will apply for the vacancies. A number of West Point cadets have expressed their interest in this Service and requested commissions therein.

For the purpose of stimulating outside research on the problems coming under the jurisdiction of Chemical Warfare, General Fries plans to request a cooperative agreement with interested technical societies. In this way he hopes to keep the profession interested in the work of the Service. It is apparent that sufficient appropriations cannot be secured now to conduct the volume of research work which should be in progress and since other countries are devoting so much attention to this kind of warfare, it appears necessary to get the outside help.

NEW YORK CITY ESTABLISHES PENSION SYSTEM

Through an enabling Act of the 1920 Legislature a pension system was created in New York City, the support of which is to be shared equally between the City and its employees. In the case of the administrative and technical forces, it provides for optional retirement at the age of sixty and mandatory retirement at seventy, with a pension allowance at the rate of one-seventieth of the average salary for the last ten years of service, for each year of service. It is thus made practicable for an employee to retire on a substantial annuity at a period in his life when he can really enjoy it. The contributions to this fund are graded according to class of service, age, and time of entrance into the City service, and range from about 4 upwards to a little over 7 per cent of the employee's salary. In case of withdrawal from the service for any cause, all contributions to this fund on the part of the employee are repaid together with interest at the rate of 4 per cent. Incidental features of the plan include pensions for disability, life insurance to the extent of one-half a year's salary, and pension to dependents in case of the employee being killed while in the performance of duty. These latter benefits are paid for wholly by the City, which also assumes the burden of financing the operation of the fund for those now in the service up to October 1, 1921, or such previous date as they may elect to avail themselves of it. Acceptance of the plan is optional on the part of present employees but is mandatory upon those who join the service after October 1, 1920, when the system goes into effect.

NATIONAL RESEARCH COUNCIL

The National Research Council has elected the following chairmen of its various divisions for the year beginning July 1, 1920:

Division of Foreign Relations, George E. Hale, Director, Mt. Wilson Observatory, Carnegie Institution of Washington; Government Division, Charles D. Walcott, Secretary of the Smithsonian Institution, and President of the National Academy of Sciences; Division of States Relation, John C. Merriam, Professor of Paleontology, University of California and President-elect of the Carnegie Institution of Washington; Division of Educational Relations, Vernon Kellogg, Professor of Entomology, Stanford University and Permanent Secretary of the National Research Council; Division of Industrial Relations, Harrison E. Howe; Research Information Service, Robert M. Yerkes; Division of Physical Sciences, Augustus Trowbridge, Professor of Physics, Princeton University; Division of Engineering, Comfort A. Adams, Lawrence Professor of Engineering, Harvard University; Division of Chemistry and Chemical Technology, Frederick G. Cottrell, Director of the Bureau of Mines; Division of Geology and Geography, E. B. Mathews, Professor of Minerology and Petrography, Johns Hopkins University; Division of Medical Sciences, George W. McCoy, Director of the U. S. Hygienic Laboratory since 1915; Division of Biology and Agriculture, C. E. McClung, Professor of Zoology, University of Pennsylvania; and Division of Anthropology and Psychology Clark Wissler, Curator of Anthropology, American Museum of Natural History of New York.

A $30,000 CONTRIBUTION FOR COOPERATIVE RESEARCH

A very striking example of how cooperative research may work out in practise is shown by the recent contribution of $30,000 made by the General Electric Co., to extend into the field of Nickel Steels, the investigations of the Committee on "Fatigue Phenomena of Metals", of the Division of Engineering of the National Research Council. This work was originally planned to cover carbon steels only, and was heretofore supported by Engineering Foundation, which appropriated $30,000 for two years' work, and by the University of Illinois which contributes the equivalent of about $12,000 in the services of Professor Moore, and in space, heat, light, etc.

Although fatigue failures of metal parts subjected to rapidly alternating stresses have been recognized for many years, the

recent era of high speeds has yielded cases of great number and importance; in connection with steam turbine shafts and rotors, airplane engines crankshafts, the hulls of steel ships, axles and shafts in railway cars, motor cars and trucks, and other machine parts. Such metal parts occasionally fail under ordinary service conditions without showing any general distortion or other symptom even when the material is known to be highly ductile. These failures are found only in parts subjected to alternations of stress repeated in some cases millions of times, and therefore are attributed to fatigue of the metal.

Recognizing the value of the results of these investigations to the industries of the country, Engineering Foundation Board about a year ago made a grant of $15,000 a year for a period of two years for the investigation of fatigue phenomena in carbon steels, under a committee of the Division of Engineering of the National Research Council. Articles of agreement were drawn up between the National Research Council, Engineering Foundation and the University of Illinois, whereby the experimental work was to be done at the University of Illinois under the direct supervision of Professor H. F. Moore, Chairman of the Committee. In addition to the services of Prof. Moore, the University furnishes the necessary space and facilities for conducting the work to the best advantage.

Professor J. B. Kommers of the University of Wisconsin, a specialist in this subject, has secured a two years leave of absence and is devoting his full time to the work, together with a staff of assistants. The apparatus is all installed and the work progressing according to schedule.

The General Electric Company has recently signed an agreement with Engineering Foundation, National Research Council and the University of Illinois, whereby it agrees to contribute an additional sum of $30,000 to extend the work to include 3 per cent and 3½ per cent nickel steel. This extension is to be considered part of the original program and no restriction is placed by the General Electric Company on the publication of results.

Although the results of this work on Nickel Steels will be of immediate commercial value to the General Electric Company, it will also be of value to other manufacturers. The attitude of the Company is therefore an unusually broad-minded one. On the other hand great economies will result from the cooperation agreed to. This is easily appreciated when one considers that the facilities, the supervising experts, and much of the apparatus for conducting these tests are already available and that the consulting services of a group of the foremost experts in the country is furnished without cost, the chief additional cost being some additional apparatus and junior assistants.

Moreover the cooperative method with its concentration of talent makes much more likely the discovery of the fundamental laws of fatigue, which will be vastly more valuable than the mere empirical information as to fatigue limits of two varieties of steel.

Thus the broad-gage, far-sighted policy of the General Electric Company demonstrates the commercial feasibility of co-operative research in the fundamentals of engineering, and opens up a large field of usefulness to the National Research Council and Engineering Foundation. It is also an illustration of the large cumulative returns likely to accrue from a wisely placed investment such as that made by the Engineering Foundation Board, which gave the necessary initial impetus to this movement.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

LECTURER ON INDUSTRIAL TOPICS. An educational organization of high standing, which is working with many of the most important industrial companies in training foreman and workmen, requires the services of an experienced factory man who is well equipped to give popular lectures on industrial topics. This man must have a forceful and attractive personality. Z-1494.

INDUSTRIAL ENGINEERING FIRM, having a number of substantial annual retainers for engineering and management of industrial plants wishes to balance its organization by the association of a Sales Engineer, competent to take full charge of advertising and sales of service. Location N. Y. C. Z-1898.

ELECTRICAL OR MECHANICAL ENGINEER, preferably a young man with one or two years field experience and some experience in office work. Location N. Y. C. Z-1893.

ENGINEER INSTRUCTOR, A Graduate Electrical Engineering course, under 30 years, required by well known school in New York City, to teach practical elements of Electricity, Mechanics and Heat, to students in electrical engineering courses, opening beginning September; position permanent; initial salary up to $2,500; future prospects dependent on qualifications on appointee; give full personal, educational and experience data and references; also religious affiliations; send photograph if possible; state salary expected. Location N. Y. City. Z-1888.

ASSISTANT SUPERINTENDENT of lighting and power department. Duties are supervising the operation and maintenance of a steam plant, a gas plant, a hydro-electric plant, and distribution from these plants for a city of 30,000 population. Man who is at present employed in similar work,—gas experience not absolutely necessary,—in smaller city and who would consider this position as a promotion. Location Virginia. Z-1872.

ASSISTANT SUPERVISOR for printing department of a large corporation. Must have experience in printing technique, and be familiar with office management as work will consist largely of forms, papers, etc., for modern office systems. Age 29 to 40. Location New York State. Z-1875.

INSTRUCTOR, Electrical Graduate Engineer, who has had some teaching and some practical experience. Location New York. Z-1853.

HEATING & VENTILATING, PLUMBING AND ELECTRICAL DESIGNERS with some field experience on installations, in office, factory, and general industrial buildings. High grade men, good personality, three years contract. Foreign service with large American interests. Z-1838.

ASSOCIATE PROFESSOR OF ELECTRICAL ENGINEERING to direct laboratories and teach direct current theory. Early promotion for right man. Thorough training and some experience required. Applicants should mail complete information with letters from references and wire for details. Location Washington. Z-1829.

POWER HOUSE ENGINEER. Plant consists of 2—2500 Kilowatt Curtis Turbines with Stirling boilers and mechanical stokers. The position would be to look after the boiler room primarily and all mechanical features of the power house. Location China. Z-1831.

ELECTRICAL ENGINEER, one who is capable of laying out a complete railway system about 18 miles in length and assuming entire charge. Location Chile. Z-1833.

ASSISTANT PROFESSOR and an instructor in electrical engineering work commencing last week in September. Applicants please state qualifications, the minimum salary they would consider and give references. Location Washington. Z-1822.

ASSISTANT TO EXECUTIVE in large commercial laboratory specializing in the testing of incandescent lamps. Technical training necessary. Age 25 to 30. Must be capable of planning and supervising tests and guiding routine thereof. Location New York. Z-1809.

TESTER, Physical tester familiar with Brimel Scleroscope work and having experience in the general physical testing of materials. Man having chemical and metallurgical training preferred. State age, experience, and salary expected. Location Pennsylvania. Z-1794.

DESIGNER, mechanical designer with practical experience on electric switching apparatus. Permanent work for the right man. State age, experience education and salary expected. Location Pennsylvania. Z-1795.

ELECTRICAL SWITCHBOARD AND PANELBOARD DRAFTSMAN to detail panels and switchboards for industrial lighting and power work. State age, experience, references, and salary desired. Location New York City. Z-1783.

MECHANICAL ELECTRICAL ENGINEER. About ten years experience for large phosphate mining property. Desire a man to supervise the installation of new work and to check up our present installation. Applicants furnish references and a record of past experience. Location Florida. Z-1788.

TECHNICAL GRADUATE, with some teaching experience and some experience in the designing and testing of electrical machinery, to take charge of a dynamo laboratory, together with some classroom work, in a day and evening technical school in New York. Write particulars, regarding age, education and experience. Location New York. Z-1789.

PRODUCTION ENGINEER. For company manufacturing full line of Gas, Coal and Electric Ranges. Preferably with technical training although not absolutely essential. Must be capable of completely organizing production system and possess full understanding of the necessities of the position. Excellent opportunity for right man. Location Ohio. Outline past experience and state salary expected to start with in first letter. Z-1792.

GENERAL MANAGER for established Steel Stamping and Rolling concern in New England. Extensive sales experience and superior executive ability necessary. State business and personal qualifications, education, experience, etc. Location Mass. Z-1793.

GRADUATES who desire to connect with a large Manufacturer of Miscellaneous Electrical Household appliances located in Chicago, Ill. Need four men from 1919 or 1920 graduate class who are ready to spend one or two years learning the details of engineering, Sales, Production or Manufacturing Department. Location Illinois. Z-1776.

ELECTRICAL DRAFTSMAN who is able to lay out wiring for industrial lighting and power work. One having had experience with some electrical contractors or engineers desired. State age, experience, references and salary desired. Location N. Y. City. Z-1782.

ASSISTANT PROFESSOR for department of Electrical Engineering in college in south. Apply by letter only giving details of experience, etc. Z-1762.

INSTRUCTOR in Electrical Engineering needed by college in South. Send full details of training and experience with first letter. Z-1763.

LABORATORY MAN for commercial and experimental testing of dry cells. Age 21 to 30. Technical graduate preferred. Must be able to supervise assistant. Location Jersey City, N. J. Z-1770.

ELECTRICAL ENGINEER for large electrical testing Laboratory. Work leads to research and development and covers a very wide range of industrial and measuring apparatus. Application by letter only. Location New England. Z-1771.

ASSOCIATE PROFESSOR for department of Electrical Engineering in college in South. Apply by letter only giving details of experience, etc. Z-1751.

INSTRUCTOR, who can take entire charge and responsibility for the courses, both as to planning and presentation, electrical engineering, laboratory work for juniors and seniors, and a course in machines for seniors. Location Texas. Z-1758.

INSTRUCTOR IN ELECTRICAL ENGINEERING. Cornell University needs several additional instructors in Electrical Engineer, duties beginning September 15th. Candidate must be an engineering school graduate. Opportunity offered to pursue post graduate work. Apply directly to Department of Electrical Engineering, Ithaca, New York, stating age, education and experience and enclose small photograph if available. Z-1727.

INSTRUCTOR to fill responsible position in a high grade technical institution in Mass. Subjects, electricity, physics and mathematics. Practical knowledge of electrical installations in textile plants desirable but not necessary. State fully experience, age, salary expected, etc. in first letter. Location Mass. Z-1711.

INSTRUCTORS for large university, in Architecture, Civil Engineering, Electrical Engineering, Mechanical Engineering, Theoretical and Applied Mechanics, Physics and Railway Mechanical Engineering. Location Middle West. Z-1701.

INSTRUCTOR to teach either or both electrical and mechanical engineering. Prefer young man with some practical experience or man who desires to come to the Pacific Coast for personal reasons. Location California. Z-1599.

INSTRUCTORS AND ASSISTANT PROFESSOR for Mechanical Engineer Department of large University. Location Illinois. Z-1603.

ASSISTANT PROFESSOR capable of handling A- C. & D- C. theory and laboratory. No other work in E. E. required next year, but will be expected temporarily to assist the Department of Physics. Location North Carolina. Z-1498.

ENGINEERS for research and development work on radio apparatus. Applicants should have an electrical engineering degree or its full equivalent in training and experience and must have had substantial experience in radio engineering. Apply by letter only to Engineering Manager, International Radio Telegraph Company, 326 Bway, New York City, stating age, education, radio experience, references, and salary desired. Z-1504.

INSTRUCTOR IN ELECTRICAL ENGINEERING for 11 months work commencing September 1st. Candidates should be graduates with an Electrical Engineering degree and should have had some experience either in practical work or in teaching. Location Ohio. Z-1359.

LABORATORY INSTRUCTOR in Electrical Engineering at a midwestern State College. Position open September 1st, 1920. Z-1292.

INSTRUCTOR IN ELECTRICAL ENGINEERING. Duties beginning September 1st, in New England Engineering College, mainly instruction in electrical engineering Laboratory. Graduate of one or two years engineering experience desired. Z-1284.

INSTRUCTORS. An examination will be held in Sampson Hall, U. S. Naval Academy, Annapolis, Maryland for selection of two instructors in Department of Electrical Engineering and Physics. Examination will be competitive and candidates found qualified will be eligible in the order of merit as determined by the Board of Examiners for appointment to fill vacancies in this department. Should more qualify than there are vacancies for at present, their names will be placed on a reserve list for later appointment to subsequent vacancies if they so desire. Appointments will be made immediately to those qualifying for the above vacancies and will thereafter be renewed annually on July 1, provided performance of duties has been satisfactory. Salary on original appointment is $2000 and an increase of $100 is given on each reappointment. Instructors are eligible for appointment as Assistant Professors, salary $2400, after 2 years, and as Associate Professors, salary $3000 after 5 years. Appointment to Professor after 10 years, salary $3600 with 10% increase every 5 years. Candidates must be American citizens. The age limits are 25 to 35 years though these may be waived in special cases. Candidates must have completed satisfactory professional courses in recognized colleges or universities. In grading the candidates, due weight will be given to past experience, letters of recommendation, etc. The examination will be written and will cover the following subjects: (1) first year college chemistry; (2) elementary and advanced physics, (more particularly those subjects pertaining to Electrical Engineering); (3) Laboratory work to correspond to (1) and (2); (4) Principles of Direct and Alternating-Current Electricity including, storage batteries, direct and alternating-current machinery elementary, telephony and radio telegraphy. Z-1064.

ASSISTANT TO CHIEF ENGINEER, a man with a good engineering education and not less than ten years experience in the design and operating of large steam power plants. Preferably one who has had training in large metal working establishments and is familiar with furnaces, gas producers

and metal working machinery and practise. Location Pa. Z-1934.

OPERATING SUPERINTENDENT, experienced in handling B. & W. Boilers, Curtis horizontal turbines, motor-generator sets, 120 ton electric locomotives operating on 2400 volts D. C. Only experienced men need apply, best of references required. State full particulars in first letter as to age, experience and when available. Location Chile, South America. Z-1940.

MEN AVAILABLE

ELECTRICAL ENGINEER, 25, graduate 1918. Naval Engineering officer during war. One year hydroelectric power plant appraisal. At present assisting General Superintendent of western power company. Desire change offering future possibilities either in Engineering or Commercial field. E-2296.

DRAFTSMAN ENGINEER, experienced on oil well machinery, manufacture of 6 in. shells and equipment for manufacturing same; general construction in large asphalt refinery; graduate E. E. 1915. Accustomed to team work. Want to connect with Company affording excellent opportunity for service, growth, and responsibility. E-2297.

ELECTRICAL ENGINEER, 25, graduate evening session—21. Six years business and electrical experience in construction field, desires position as Assistant to Industrial, Sales or Construction Engineer. Location until June 21st. Must be New York City. E-2298.

EXECUTIVE ENGINEER, Columbia Graduate, E. E., experienced in plant construction; factory management, financing; as general manager; and estimating. American. Age 45, Christian. Salary $6000. If desired could invest $6000 and enlist excellent banking connections. E-2299.

POWER ENGINEER, good executive, 14 years experience operation, maintenance and supervision of power plants, steam and hydraulic. Desire connection with public utility or will undertake the organization or reorganization of power department for industrial concern. Location Middle Atlantic or Southern States. Available one month after closing agreement. E-2300.

GRADUATE ELECTRICAL ENGINEER, 27, married, desires position as Assistant Engineer in General municipal or Public Utilities work where some experience and good judgment are required. In charge of electrical construction and maintenance for two years. Handling 35 men. Can furnish references or recommendations. Salary depends on location. E-2301.

GRADUATE E. E. experienced designer of alternating current motors and generators; also fractional horse power direct and alternating current motors. Desires position with an aggressive manufacturing concern. Location anywhere. Available immediately. Salary $2600. E-2302.

SALES ENGINEER desires connection vicinity Chicago. Technical college graduate. General Electric Test experience and commercial training. Salary $2500. Available soon. E-2303.

ELECTRICAL MECHANICAL ENGINEER, technical graduate, 17 years experience mostly in responsible charge of design, construction and operation of industrial power systems. Have successfully handled several large projects requiring engineering skill of the highest order. Available soon. E-2304.

ELECTRICAL ENGINEER, 31, married. Broad experience; electrical contracting, transformer and motor testing, transformer and motor designing, sales engineering and quotation work with manufacturing companies. Desire location in the middle west or Pacific Coast. Asst. or chief engineer of industrial concern preferred. Salary $3600. E-2305.

YOUNG MAN, 25, desires position with engineering or construction firm where opportunity for an executive position in future is good. Technically trained along electrical lines. Four years maintenance experience with large public utility and 3 years business experience. Best references. Available on short notice. E-2306.

ENGINEER, Supervising and Operating. Seeks position of responsibility in charge of electrical and mechanical industrial power equipment. M. I. T. Graduate, 10 years experience, in the design, installation, testing, operation and maintenance of industrial apparatus. Married. Location desired New York City or vicinity. Available on short notice. E-2307.

CONSTRUCTION ENGINEER desires to exchange services for course of instruction in technical school or University. 15 years experience electrical construction, and operation machine shop and foundry practise. Semi-technical education. E-2308.

GRADUATE ELECTRICAL ENGINEER, 1915, knowledge of electrical apparatus of small and medium size and manufacture of same. Experience in handling high voltages, writing specifications and in selecting apparatus to fill customers' specifications. Married. Desire position in Engineering Sales or executive position with small electrical manufacturing concern. E-2309.

ELECTRICAL ENGINEER graduate desires position with manufacturing or construction company in middle west. Two years experience construction work and drafting, one year electrical officer on submarine. Single, 27, available about Sept. 15. Minimum salary $2500. E-2310.

RAILROAD TELEPHONE INSPECTOR, young with 5 years practical experience in various lines of railroad telephony. Good technical education. Desires change offering position with broader opportunities. E-2311.

ELECTRICAL ENGINEER, 25, familiar with preliminary surveys, operation and maintenance work desires a position with hydroelectric concern in the Northwest. Salary $175. E-2312.

ELECTRICAL ENGINEER, desires business, engineering or sales position with a growing concern. Fifteen years experience which has included design, construction and operation of electric railway, power-house and substation work; also correspondence and sales experience and motor application for industrial plants. Salary $300.00 per month. E-2313.

ELECTRICAL ENGINEER, 24, single, seeks larger field. Degree from American College. One year construction experience. One year efficiency and experimental, eighteen months technical salesman on heavy electrical machinery in Great Britain. Located at present in London. Conversant with foreign business methods. Knowledge of French and Spanish. Present salary $3500. E-2314.

ASSISTANT TO CONSULTING ENGINEER, of large industrial organization. 30 years experience including 4 as millwright and locomotive builder; 5 as chief draftsman; 5 estimating and sales manager; 5 chemical engineering research. Also important consulting work, America, England and Australia. Lecturer at several leading Universities and Technical Institutes. Editor proceedings Mining Engineering Society and good writer technical articles and advertisements. Special knowledge of design and working electric furnaces. Would consider position as Professor, Editor or Secretary of Technical Society. E-2315.

GENERAL ENGINEERING WORK, wanted by member; now employed as investigating engineer by high grade Investment Securities House in New York. He desires a change that will give him active (partial or entire) outside or road work in which he may utilize twelve years experience in sub and central station design. Installation and operation, with the country's largest central station company, and four years on hydro and substation design and hydraulic investigations and tests with a well known engineering company. E-2316.

ELECTRICAL SUPT. of operation and maintenance. Technical graduate. 18 years practical experience on all kinds of operating and load dispatching. Chief Electrician of central stations, both lighting and railway and Superintendent of lighting, railway and power substations indoor and outdoor type. Desires position as superintendent of operation and maintenance, with Utility Company or large Industrial Concern. Age 34, married, references. At present employed have good reasons for change. E-2317.

ELECTRICAL ENGINEER, technical graduate, 5 years experience, powerhouse, substation and electric railway equipment and maintenance. Pump installations. Considerable experience on cable specifications and inspections. Initial salary $200 per month. E-2318.

YOUNG MAN, 23, B. S. in E. E., 1920. Fluent Spanish and French. Desires position in U. S., foreign country with a successful firm. Available January 1921. E-2319.

OPERATING ENGINEER, technically educated, ten years General Electric Test, fifteen years steam and hydro-electric generation, high tension transmission and distribution, proved executive ability, at present holding position as Superintendent of Power large hydroelectric company, desires change. Correspondence and interview solicited. Age 40, married, present salary $5000.00. Address E-2320.

ENGINEER, Technical graduate, 2 years G. E. Test, 2 years Assistant Chief in 50,000 Kw. station, 1 year Superintendent of betterment work in 3000 Kw. station and 55 ton ice plant, desires permanent connection with chance for advancement. Salary desired $3600. E-2321.

ENGINEER AND MANAGER. Technical and practical. Two years as Manager of electric and gas properties. Two

years traveling operating and supervising engineer for large holding company. Ten years engineering and operating with The New York Edison Co. Prefer location in East. Available on 45 days notice. Salary $6000. per annum. E-2322.

MECHANICAL OR PLANT ENGINEER. Technical, graduate excellent executive; successful in handling all classes of men; diplomatic and tactful. 18 years experience in electrical and mechanical including; installation and maintenance; industrial plant, power, heating and lighting layout; organization and production engineering, and purchasing. E-2323.

YOUG MAN, age 25, married; partial technical training. Five years electrical experience actual construction, engineering, and drafting, designing of power plants and substations, switchboards and general electrical installations. Desires position with prospects for advancement. Location Philadelphia or near by. Available immediately. E-2324.

YOUNG ELECTRICAL ENGINEER. Cornell '18, desires connection with consulting engineer or small growing technical concern. Practical experience, personality, vigor, ability and judgment. E-2325.

ENGINEER SUPERVISING or operating chief; position of responsibility in charge of power plants or plant and mechanical and electrical industrial equipment especially where proportionately large amount of steam and power is used in manufacturing; 20 years experience. Married. Location immaterial. Salary commensurate with position. Immediately available. E-2231.

ELECTRICAL ENGINEER. B. S. in E. E., 12 years experience in electric meters and instruments; distribution control, signal and telegraph apparatus; insulating material. Desires position as assistant to production engineer or as Manufacturers representative. American, 31, married. E-2327.

ELECTRICAL ENGINEER. 30, married, technical graduate Westinghouse Test Course. Employed as electrical engineer and superintendent of Electrical Department, 400 men, 1600 motors up to 5750 hp., 125 cranes, turbo-generators totalling 44,000 Kw. Desires position as Electrical Engineer with large industrial concern. Available 30 days notice. Salary expected, $6000.

PRACTICAL MECHANICAL and Electrical Engineer desires position as assistant to supervising engineer on electric power station or electric railway construction work. Have had 6 years practical experience in mechanical and electrical construction and maintenance work; 4½ years supervising inspecting and testing of machinery and electrical equipment for foreign governments; 12 months as staff engineer in an industrial plant, handling estimates, specifications, machinery installation and maintenance supervision. Graduate marine and stationary engineer; with I. C. S. Electrical Engineering Diploma. Age 28, married, location immaterial. Salary $2400 to start. E-2329.

ELECTRICAL CONSTRUCTION or operation preferred, research or design instruction and drafting acceptable in order named. Two years Westinghouse Shop and test work, six months Goodrich design and drafting work. Technical graduate Johns Hopkins. E-2330.

TECHNICAL GRADUATE, four years laboratory experience in magnetics, thoroughly versed in modern methods of testing electrical steels and materials, desires position with manufacturing concern in need of man with the above training and experience. Salary commensurate with duties and location. Available on reasonable notice to present employer, married, age 20. E-2331.

MECHANICAL AND ELECTRICAL ENGINEER, Technical and Executive, 14 years practical experience in electrical and mechanical construction and sales, including power plants both central station and industrial. Married. Services available October 1st. Minimum salary $5000 per annum. E-2332.

ELECTRICAL ENGINEER, technical graduate, seven years experience desires opportunity for broader business training as assistant to chief executive of manufacturing plant. Generally familiar with plant management, apparatus design, production, cost finding and accounting. At present employed as executive in engineering department of large corporation. E-2333.

ENGINEER, Age 44, 25 years experience in design construction and operation of steam, electrical systems and industrial layouts, now employed Chicago; desires position vicinity Los Angeles, Cal. E-2334.

MECHANICAL SUPERINTENDENT, for textile mills. Technical graduate, thirty nine, member. Wide experience in mill work including the design and installation of electric drives. Also thorough training in steam engineering using both coal and fuel oil. Good executive. Best references. E-2335.

ASSISTANT ENGINEER, 25, married, technical education 5 years experience in contracting, testing and construction. Last two years with electrical traction company on substation construction work, comprising general supervision of switchboard construction. E-2336.

ELECTRICAL ENGINEER, of broad experience, available for employment in America or abroad. College graduate. Sixteen years with leading manufacturer, testing hydro-electric construction, America and abroad, design, development, investigation, export sales, speaks French and is familiar with conditions in India. E-2337.

GRADUATE ELECTRICAL ENGINEER, B. S. Design work-power stations and transmission five years. Industrial light and power three years. Steam turbines one year. Electrical manufacturing office three years. Electrical construction work one year. Test three years, factory and Edison Co. Business three years. Executive experience. Now employed. Either commercial or technical position. E-2338.

ELECTRICAL AND MECHANICAL ENGINEER, graduate, 6 years university training and 8 years practical experience. Electrical design, construction and maintenance. Mechanical installation and maintenance. Experience in handling personnel. Administrative duties. Business course 30% complete. E-2339.

ELECTRICAL ENGINEER. Technical graduate. Age 29. Five years broad experience design and purchasing. Capable, energetic. Easily adapted to new situation. Wants permanent position. Available 30 days notice. Salary $2700. E-2342.

EXECUTIVE, technical graduate in Electrical Engineering. Public Utility and Metal Manufacturing experience. Available on thirty days notice for allied position or with efficiency or sales organization. Minimum basis $5000, prefer lesser fixed salary with share or bonus proportionate to results. E-2340.

ELECTRICAL ENGINEER, with 14 years exceptionally broad experience in the electrical utility and hydroelectrical field covering both design, construction, testing and operation of modern power systems (incl. electrical furnaces). Specialty. Investigation and relief of difficult operating problems. At present in charge of research dept. of Power Company: Age 37, Married. E-2341.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—W. Ammen, 133 Franklin Ave., Mt. Vernon, N. Y.
2.—L. J. Clements, 469 Magnolia, Portland, Ore.
3.—Oliver H. Horner, c/o Black & Veatch, 507 Interstate Bldg., Kansas City, Mo.
4.—Wilfred Langille, Marion Sta. Public Service Elec. Co., Jersey City, N. J.
5.—Harry Symes, Lyne Mfg. Co., Orange, Va.
6.—David R. Thomas, Otis & Co., Cleveland, Ohio.

PERSONAL

L. B. RITCHIE has been appointed general eastern sales manager for the Burke Electric Company, with headquarters at 30 Church Street, New York City, where he has for some time been sales representative for the New York territory.

GEORGE M. BASFORD, president of the Locomotive Feed Water Heater Company, New York, has been appointed a Trustee of United Engineering Society to fill the vacancy caused by the death of E. Gibbon Spilsbury. The term will expire at the annual meeting in January, 1923. Mr. Basford was formerly a member of the Council of the Mechanical Engineers.

C. D. YOUNG, general supervisor of stores, Pennsylvania System, Broad Street Station, Philadelphia, and vice-president of the American Society for Testing Materials, has

been appointed by the American Society for Testing Materials as its representative on Engineering Council to succeed Mr. Albert Ladd Colby.

L. L. MYERS has been appointed general western sales manager for the Burke Electric Company. Mr. Myers' headquarters will continue to be in the Illuminating Building, Cleveland, Ohio, where he has been the Burke Electric Company's sales representative for the Cleveland territory for several years.

G. SANFORD DAVIS is leaving the employ of the Canadian General Electric Co., Ltd., where he has been for the past fifteen years, in the Engineering Department, and lately as District Engineer in the Montreal office. He will enter the employ of J. M. Robertson, Ltd., Consulting Engineers, in the Cornstine Building, Montreal.

H. J. VAN DER BIJL, Research Physicist with the Western Electric Company, New York, will soon leave the United States. He has accepted the call of his birthplace and will proceed immediately to his home at Pretoria, British South Africa, where he has been appointed Scientific and Technical Advisor to the Bureau of Mines and Industries of the Union of South Africa. His duties will consist for the main part in establishing a bureau of standards for the authorities of the Dark Continent. Dr. Van der Bijl comes from an old family of Boers. During the time that Lord Roberts was operating about Pretoria, the father of the well-known scientist was mayor of the doomed city. A few years later Dr. Van der Bijl finished his studies at Victoria College, British South Africa, thereafter entering the University of Leipsic where he gained his doctorate. He came to the United States in 1912, joining the engineering department of the Western Electric Company, and for the last seven years he has been a prominent member of the personnel of its research laboratories at West Street. He was instrumental in devising several of the improvements in telephone and telegraph instruments which the Western Electric Company has brought forth during the last few years. Dr. Van der Bijl became a Member of the A. I. E. E. in 1917.

OBITUARY

EDWARD MARTIN SHEPARD, JR., electrical engineer, of Detroit, Michigan, died suddenly of pneumonia in that city Mar. 24th, 1920. He was born in Springfield, Missouri, Aug. 27th, 1889. He was graduated from Drury College in 1910, and went directly to Cornell University, where he was graduated in 1913 with the degree of electrical engineer. In the fall of that year he became connected with the Wagner Electrical Company, of St. Louis, and was soon sent to act as the engineer in their branch in Detroit. He resigned from this work to become a partner in the firm of Little & Shepard, Electrical and Mechanical Engineers, in Detroit. Immediately upon the declaration of war, he enlisted and received his commission as First Lieutenant at Fort Sheridan the summer of 1917. From Camp Humphries, Va., he was sent over seas Sept. 19, 1918 in command of B Company of a service battalion of the 544th Engineers, and was commissioned Captain May 1, 1919. In the battle of the Argonne his company was in charge of keeping open lines of transportation. After the armistice, his company did much work in road construction in that region, and later in the neighborhood of Brest. Captain Shepard was honorably discharged from service at Camp Grant, Illinois, Aug. 1, 1919. He returned to Detroit and immediately entered upon a responsible connection with the engineering department of the Detroit-Edison Company, which position he held at the time of his death. He came of good old New England stock, the last of a long line of Mayflower descendants, being 10th in descent from Governor Wm. Bradford, and a most promising career was cut short by his death.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (JULY 1—31, 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

APPLIED AERODYNAMICS.

By G. P. Thomson. N. Y., The Norman W. Henley Publishing Co. 292 pp., illus., charts, diagrams, plates, 10 x 7 in., cloth, $12.50.

CONTENTS: Part I. Performance: General Outline; Physical Theory; Experimental Methods; Struts and Wires; Wing Structure; Bodies, Fuselages, etc.; Landing Gears and Miscellaneous Resistances; Airscrews; Large Aeroplane; Prediction of Performance.

Part II. Stability and Control: Centres of Pressure and Moments; Tail Planes and Downwash; Mathematical Discussion of Stability; Longitudinal Stability; Lateral Stability; Controllability.

This book is the work of a former officer in the Royal Air Force, who, during the War, was in touch with both the demands from the Front and the attempts made to fulfil those demands from home sources. The results presented are drawn from data accumulated during the War, some of which has been or will be published in the Reports of the Advisory Committee for Aeronautics, and the author has also had free access to the staff and records of the Aircraft Manufacturing Company. The work is concerned only indirectly with the mechanical side of aircraft design, but it specializes upon aerodynamics as a branch of engineering, though an account is also given of such progress as has been made on this side of physics from an engineer's point of view.

A number of suggestions for further inquiry and research are made, such as the problems relating to the interaction of aeroplane fuselages, nacelles and the airscrews attached to them.

The importance of full-scale work is emphasized, and the problem of stability is dealt with at length. The question of how heavily the wings of an aeroplane should be loaded is discussed and the subject of abnormally large aeroplanes is also taken up. The information given was up-to-date at the time of writing and pains have been taken to point out the cases in which there was any considerable probability of error.

THE COAL CATALOG, COMBINED WITH COAL FIELD DIRECTORY FOR THE YEAR 1920.

Containing Explanatory Articles on Rank, Usage, Analysis, Geology, Storage and Preparation of Coals. Compiled and published annually by Keystone Consolidated Publishing Company, Pittsburgh. 1133 pp., illus., maps, tables, 12 x 9 in., cloth, $10.

The second edition of the Coal Catalog, in addition to describing and listing the coal mines of the United States, with the output and operating companies, has added much new data such as the fusion points of ash from the various coals, the specific gravities and weights of coals and the so-called "fuel ratios." A list of national and local associations is included as well as the wholesale dealers in the larger towns and cities. A Directory section follows each state.

A METALLOGRAPHIC STUDY ON TUNGSTEN STEELS.

By Axel Hultgren. N. Y., John Wiley & Sons, Inc., Lond., Chapman & Hall, Ltd. 1920. 95 pp., illus., 43 plates, tables, 9 x 6 in., cloth, $3.00.

As the question of tungsten steels has been studied by several investigators whose views have not always agreed, it is the purpose of this work to bring about a clearer understanding by presenting certain new facts and problems and by critically examining previous results and opinions.

The subject is divided into two sections: (1) The transformations of tungsten steel during different heat treatments and the structures thereby formed; (2) Carbides in tungsten steels. Each section contains a review of the results and opinions of previous investigators and the author's own results and conclusions, based on his metallographic investigations at the Institute of Technology of Charlottenburg, the Royal Institute for Testing Materials, Stockholm, and in the Laboratory of the S K F Ball Bearing Co., Gothenburg, Sweden.

The paper was written in Swedish in 1918. In its present form it includes a translation of the Swedish paper as well as an appendix containing a critical review of the investigations on tungsten steels of Honda and Murakami.

POPULAR OIL GEOLOGY.

By Victor Ziegler. Second edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 171 pp., illus., chart, maps, tables, 7 x 5 in., flexible cloth, $3.00.

CONTENTS: The Rise and Development of the Petroleum Industry.—The Composition and Properties of Oil and Gas.—The Origin of Oil and Gas.—Rocks and their Properties.—Stratigraphic Geology.—The Arrangements and Structures of Rocks.—The Reservoirs of Oil and Gas.—The Laws of Migration and Accumulation of Oil and Gas.—Maps and their Uses.—Oil Structures and Oil Fields.—Popular Fallacies in Oil Geology.—Prospecting and Developing Oil Lands.—Oil Shales and their Utilization.—Oil Investments.

The second edition of this work on oil geology has been partially rewritten and new material along the more theoretical lines of geology has been added. The principles important in the examination of prospective oil land have been emphasized and the work of the oil geologist described in some detail. The work is intended to make intelligible to the laymen the fundamental principles of oil geology and is written in as clear and simple language as possible.

PRACTICAL CHEMISTRY.

Fundamental Facts and Applications to Modern Life. By N. Henry Black and James Bryant Conant. N. Y., Macmillan Co., 1920. 474 pp., illus., plates, 8 x 5 in., cloth, $2.00.

It is the purpose of this book to present the fundamental facts of chemistry and to show by the applications of those facts to experiences of everyday life that the subject is real and practical. The economic significance of chemistry and the allied industries has been stressed and the chemistry of growing things has also been considered. Only such topics have been included as young people can grasp and find useful. The book is adapted for class use as a textbook.

SPOT AND ARC WELDING.

By H. A. Hornor. Phila. and Lond., J. B. Lippincott Co., copyright 1920. 296 pp., illus., charts, diag., 8 x 5 in., cloth.

Although electric welding has long been used in repair work, there is still considerable hesitancy in applying it in new construction work. This volume is intended to overcome this hesitancy by presenting the results of work already done. The data of tests made in the spot welding of heavy steel slates by the Emergency Fleet Corporation is given in full and the underlying question of arc-welding processes is dealt with at length.

The appendix contains lessons in electric welding and the regulations for the application of electric arc welding to ship construction issued by Lloyd's Register of Shipping.

STORAGE BATTERIES.

A Practical Presentation of the Principles of Action, Construction, and Maintenance of Lead and Non-lead Batteries and Their Principal Commercial Applications. By Morton Arendt. Chic., American Technical Society, 1920. 136 pp., illus., plate, tables, 7 x 6 in., flexible cloth.

CONTENTS: Theory and Principles.—Lead Batteries.—Non-lead Batteries.—Testing Storage Batteries.—Regulation of Generator in Charging Storage Batteries.—Commercial Applications.

Important changes have taken place with the last ten years in the construction of the storage battery, and the principles of the design and manufacture of this "savings bank" of the electrical industry have been studied with the view of making it even more efficient. The importance of proper charging methods, testing, locating and remedying troubles are treated in detail in this volume, which also covers the methods of use by the large generating stations, in the telephone and telegraph industries and in electric vehicles. The work is adapted for home study by beginners as well as for experts.

THEORIE DES HELICES PROPULSIVES, MARINES ET AERIENNES.

Et des Abions en Vol Rectiligne. By A. Rateau. Paris, Gauthier-Villars et Cie, 1920. 159 pp., diagrams, tables, 10 x 7 in., paper. (Gift of author.)

The first part of this work deals with the theory of screw propellers, both marine and aerial, and is an extension of the author's previously expressed hypothesis. A large number of formulas are worked out and compared with the results derived from experiments.

The second part, which takes up the theory of planes in rectilinear flight, is based on four papers presented to the Académie des Sciences in 1919, with some corrections and additions, particularly the formulas for the angle of incidence and speed of ascension, the effect of the angle at which the axis of the propeller is inclined, the characteristic curves of planes and the changing of speed rotation indicated by their discontinuity, etc.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Cincinnati.—July 27, 1920, The Engineers Club of Cincinnati. Organization meeting and election of officers as follows: Chairman, J. D. Lyon; Secretary-Treasurer, Leo Schirtzinger; Executive Committee, Prof. A. M. Wilson, C. W. DeForest, and Wm. S. Culver. Attendance 20.

Ithaca.—May 28, 1920, Technology Club, Syracuse, N. Y. Subject: "Alternating-Current Railways" Speaker: Mr. R. E. Hellmund, of the Westinghouse Elec. & Mfg. Co. Preceding the meeting a get-together dinner was held in the Onandaga Hotel in honor of the speaker of the evening. Attendance 100.

Kansas City.—June 25, 1920, University Club Rooms. Subject: "The Structure of the Automatic Telephone Exchange." Speaker: Mr. Artnur B. Smith, of the Automatic Electric Company, Chicago. Attendance 28.

Vancouver.—June 16, 1920, Board of Trade Bldg. Reorganization meeting. Two visiting members from the Toronto Section outlined the recent activities of that Section. Attendance 15.

June 22, 1920. Annual meeting. Election of officers as follows: Chairman, Frank Sawford; Secretary, T. H. Crosby; Executive Committee, Messrs. J. R. Read, R. F. Hayward and F. W. McNeill. Attendance 26.

PAST BRANCH MEETING

Drexel Institute.—June 16, 1920. Election of officers as follows: Chairman, George Davis; Secretary, Franklin Peterson; Treasurer, Holmer S. Kepner. Attendance 16.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED AUGUST 12, 1920

Adams, Charles W., Supt. & Engineer, Brush Dept., United States Graphite Co., Saginaw, Mich.

Aldrete, Antonio, Electrical Engineer, Cia Hidroelectrica e Irrigadora del Chapala S. A., 11d del Juarez No. 682, Guadalajara, Mexico.

Andres, Paul G., Asst. Professor of Electrical Engineering, Michigan Agricultural College, E. Lansing, Mich.

Appleman, Glen, Electrical Engineer, The Lehigh Valley Lt. & Pr. Co., 8th & Hamilton Sts., Allentown, Pa.

Baerer, Eugene A., Test Engineer, The Lehigh Valley Light & Power Co., Hauto; res., 3 North Lehigh St., Tamaqua, Pa.

Bankus, John, Electrical Engineer, Portland Railway, Light & Power Co., 507 Electric Bldg., Portland, Ore.

Beckel, George J., Meter Man Public Service Co.; res. 1617 Oak St., Chicago Heights, Ill.

Benington, William F., Electrical Designer, Semet-Solvay Co., Syracuse, N. Y.

Bente, Saunders H., Division Inspector, Public Service Company of Northern Illinois, Kankakee, Ill.

Betts, Andrew G., Meter Supt., Puget Sound Power & Light Co., 1306 A St., Tacoma, Wash.

Bickel, Joseph W., Electric Meter Foreman, Division F. Public Service Company of Northern Illinois, Chicago Heights, Ill.

*Binder, Albert A., Service Engineer, Westinghouse Electric & Mfg. Co.; res., 3854 Westminster Place, St. Louis, Mo.

Blair, Wayne C., Industrial Engineer, Kansas City Power & Light Co., 1500 Grand Ave., Kansas City, Mo.

Boneschi, Arturo, Dealer in Electrical Apparatus, Via Romagnosi No. 1, Milan, Italy.

Boring, Herbert A., Sales Agent, General Electric Co., 609 Colman Bldg., Seattle, Wash.

Boyere, Emery E., Interior Wireman, B. & G. Dept., General Electric Co.; res., 311 Sassafras St., Erie, Pa.

Brainard, Charles D., Meter Engineer, Chicopee Electric Light Dept., Chicopee; res., 133 Springfield St., Springfield, Mass.

Bravo, Ricardo S., Jr., Chief Electrician, Sugarland Industries, Sugarland, Texas.

Brown, Robert Q., Acting Instructor in C. E., University of Washington, 4522 18th Ave., N. E., Seattle, Wash.

Browning, Hardy P., Captain, Signal Corps, United States Army, Fort Sam Houston, Texas.

Bryant, Le Roy C., Manager's Assistant, Chicopee Electric Light Dept.; res., 10 Riverview Terrace, Chicopee, Mass.

Buyers, Charles S., Engineer-in-Charge of Contract Dept., Messrs. Crompton & Co. Ltd., Chelmsford, Eng.

Calvert, Leslie W., Chief Electrician, Weyerhaeuser Timber Co., Everett, Wash.

Campbell, Allan B., Electrical Engineer, Board of Railroad Commissioners, Des Moines, Iowa

Carpenter, James W., Industrial Engineer, Union Electric & Power Co., 12th & Locust Sts., St. Louis, Mo.

Casey, Francis R., Electrical Engineer, Western Electric Co.; res., 6820 S. Marshfield Ave., Chicago, Ill.

Chakow, Sig. J., Asst. Electrical Engineer, Condron Co., 1433 Monadnock Block, Chicago, Ill.

Chamberlain, Leon H., Switchboard Engineer, The Pacific Tel. & Tel. Co., 835 Howard St., San Francisco; res., 922 Santa Barbara Road, Berkeley, Cal.

Cheever, Allston H., Electrical Draftsman, Richard D. Kimball Co., 6 Beacon St., Boston; res., 14 Centre St., Cambridge, Mass.

Coakley, Patrick S., Operator, Electrical Division, The Panama Canal, Gatun, Canal Zone.

Cobb, Frank E., Repairman, Union Electric Light & Power Co.; res., 2630 Ann Ave., St. Louis, Mo.

Cockburn, Donald, In charge of Electrical Construction, Aberthaw Construction Co., Boston; res., 48 Cottage St., Melrose, Mass.

Coffin, Frank C., New England Power Co., 35 Harvard St., Worcester, Mass.

Conrad, Lester L., Laboratoryman, So. California Edison Co., 132 Llewellyn St., Los Angeles, Cal.

Corona, Felix F., Consulting Engineer, Jefe del Laboratorio de Electrotecnia de la Universidad de Chile, Casilla 1816, Santiago, Chile, S. A.

*Corson, Le Roy, Asst. Engineer, New York & Queens Electric Light & Power Co., Long Island City; res., 203 Warburton Ave., Yonkers, N. Y.

Counts, Hilda, Graduate Student, Electrical Engineering, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Cox, George C., Cox & Son, Sylva; res., Cullowhee, N. C.

Crawford, Vernon W., Designing Engineer, General Electric Co., Pittsfield, Mass.

*Darland, Alvin F., Chief Electrician, Todd Dry Dock & Construction Corp.; res., 3640 Thompson Ave., Tacoma, Wash.

David, Edward Ivor, Chief Electrical Engineer, Powell Duffryn Co., Aberdare, South Wales, British Isles.

de Coutouly, Gustave Charles, General Direction of French Services (Statistics), 65 Broadway, New York, N. Y.; res., S. Norwalk, Conn.

Denn, Edward J., In charge Electrical Work, Richard Turner Co.; Consulting Engineer, Acme Engineering Service, Springfield, Mass.

Dunlap, Edward F., Traveling Salesman, Economy Fuse & Mfg. Co., Chicago, Ill.

Eckert, William S., Vice-President, National Conduit & Cable Co., Inc., Hastings-on-Hudson, N. Y.

Edwards, Wrightman, Sales Engineer, National Conduit & Cable Co., Inc., 41 Park Row, New York, N. Y.

Fairfield, Donald H., Chief Electrician, The American Brass Co.; res., 971 Howland Ave., Kenosha, Wis.

Ferraz, Raul de Oliveria, Contracting Engineer, Rua Libero Badaro 67; res., Automovel Club, S. Paulo, Brazil, S. A.

Field, Ernest H., Estimating Engineer, Crompton & Co., Ltd., Chelmsford, Eng.

Fisher, William H., Electrical Draftsman, Goodyear Tire & Rubber Co.; res., 1623 Preston Ave., Akron, Ohio

Fletcher, John A., Asst. Dist. Manager, Canadian General Electric Co., Ltd., Vancouver, B. C.

Frankel, Charles B., Asst. Engineer, Underground Extensions, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

Franklin, George E., In charge of Testing Dept., Chamberlain & Hookham Meter Co., Ltd., 243 College St., Toronto, Ont.

Franklin, Townsend U., Sales Engineer, Morgan Crucible Co., 519 W. 38th St., New York, N. Y.; res., Warsaw, Ind.

Friday, Casper S., Test-man, General Electric Co.; res., 203 Seward Place, Schenectady, N. Y.

Gifford, Clarence C., Electrical Engineer, Los Angeles Shipbuilidng & Drydock Co., San Pedro, Cal.

Glass, Howard G., Asst. Operator, Substation, Pennsylvania Water & Power Co.; res., 3127 Guilford Ave., Baltimore, Md.

Godwin, Jimmie Jean, Utility Clerk, Union Electric & Power Co., 315 N. 12th, St. Louis, Mo.

Govier, Charles E., Associate Professor, Telephone Engineering, Pennsylvania State College, State College, Pa.

Grant, Royal E., Industrial Research Engineer, 790 Pleasant St., Dracut, Mass.

*Green, James L., Engineer, Northern Electric Co., Ltd., Regina, Sask., Canada

Gregory, Philip S., Electrical Engineer, Shawinigan Water & Power Company, Montreal, Que., Can.

GROSS, FRANK W., Master Signal Electrician, Signal Corps, U.S. A., Dept. Signal Office, Ft. Sam Houston, Texas.
HAWKINS, ROY A., Chief Electrician The Moctezuma Copper Co., Pachuca, Hidalgo, Mexico.
HENYAN, GEORGE W., Commercial Engineer, Lighting Dept., General Electric Co., Schenectady, N. Y.
HERROLD, CHARLES D., Street Car Industrial Co., 475 S. 1st St., San Jose, Cal.
HILLS, CHARLES B., Electrical Supt., Bathurst Lumber Co., Bathurst, N. B.
HOBSON, ALBERT, Transmission & Protection Engineer, Southwestern Bell Telephone Co., Dallas, Texas.
HOFERT, FRED A., Foreman, Victor Electric Corp., 236 S. Robey St., Chicago; res., 732 S. Humphrey Ave., Oak Park, Ill.
HOLCOMB, PHILO, JR., Multiplex Telegraph Attendant, Western Union Telegraph Co.; res., 431 Central Ave., Atlanta, Ga.
HOOD, CLIFFORD F., Electrical Engineer, Electrical Cable Works, American Steel & Wire Co.; res., 738 Main St., Worcester, Mass.
HOPKINS, HENRY D., Electrical Draftsman, Commonwealth Edison Co.; res., 6057 Drexel Ave., Chicago, Ill.
HRUBES, JAMES A., Engineer, Chicago Elevated Railroads, 72 W. Adams St., Chicago, Ill.
HUBBERT, WILLIAM, Electrical Foreman, Skinner & Eddy Corp.; res., 1323 13th Ave. South, Seattle, Wash.

SCOTT, JAMES P., Engineer's Asst., Bell Telephone Company of Pennsylvania; res., 869 Lockhart St. N. S., Pittsburgh, Pa.
SCOTT, RALPH ALLEN, Lieut., U. S. Navy, Electrical Officer, U. S. S. Arizona, New York, N. Y.
SECKMAN, JOHN R., Sales Engineer, International Machinery Co., Casilla 107-D, Santiago, Chile, S. A.
SELF, WAYNE K., Electrician, Weirton Steel Co., Weirton, W. Va.; res., 622 North 5th St., Steubenville, Ohio.
SKINNER WILLIAM EUGENE; res., 545 Van Buren St., Milwaukee Wis.
SMALLIDGE, FRANK E., President & Manager, Electric Supply Co., 19 Wenatchee Ave. South, Wenatchee, Wash.
SMITH, D. BOYD, Asst. to Electrical Engineer, Nevada Consolidated Copper Co., McGill, Nev.
SMITH, JOSEPH W., Electrical Engineer, Colombia Products Co., Cartagena, Colombia, S. A.
SOUTHGATE, IRVING J., Foreman, Eastman Kodak Co., Kodak Park; res., 474 Flower City Park, Rochester, N. Y.
ST. CLAIR, HARRY, Signal Engineer, Chattanooga Railway & Light Company, Chattanooga, Tenn.
SUBERS, C. VAN ARTSDALEN, Asst. Electrical Designer, The Philadelphia Electric Co., Philadelphia; res., Ashbourne, Pa.
THOMAS, HUGH M., Asst. Supt., Gatun Locks, Gatun, C. Z.
THOMPSON, CHARLES S., Switchboard Operator, 925 W. 9th St., Wilmington, Del.
THOMPSON, THEO W., Asst. Foreman, Allis-Chalmers Mfg. Co.; res., 434 64th Ave., W. Allis, Wis.

Trompen, Nicholas J., Chief Cable Inspector, Brooklyn Edison Co., 360 Pearl St.; res., 1320 73rd St., Brooklyn, N. Y.
Tseng, Chou C., Electrical Engineer, Peking Chinese Electric Light & Power Co., Peking, China
Turley, Lester J., Engineer of Electric Power, Chief Engineer's Dept., Los Angeles Railway, 747 Pacific Electric Bldg., Los Angeles, Cal.
Tuttle, Walter William, Electrical Draftsman, Public Works Dept., U. S. Naval Station, Pearl Harbor, T. H.
Underwood, Cecil H., Railway Equipment Engineering Dept., General Electric Co., Schenectady, N. Y.
Vodicke, Frank J., Draftsman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 101 W. Hutchinson St., Edgewood, Pa.
Wagner, C. E., Shop Foreman, Portland Railway Light & Power Co.; res., 1068 E. Morrison St., Portland, Ore.
Watson, Leon A., Draftsman, Electric Controller & Mfg. Co., 2700 E. 79th St., Cleveland, Ohio.
Waugh, Louie E., Electrician, Production Dept., Detroit Edison Co., Dehay Plant; res., 244½ Casgrain Ave., Detroit, Mich.
Webster, Clarence A., Senior Electrical Inspector, United States Shipping Board, Hog Island; res., 2522 So. 58th St., W. Philadelphia, Pa.
Webster, Marshall, Equipment Engineer, Western Electric Co., Chicago; res., 156 N. Oak Park Ave., Oak Park, Ill.
Wessels, Louis H., Electrician, Federal Shipbuilding Co., Kearny; res., 105 Union St., Jersey City, N. J.
West, Austin W., Resident Engineer, Lockwood, Greene & Co., 1530 Healey Bldg., Atlanta, Ga.
Westlake, Sherwood V., Electrical Tester, General Electric Co., River Works, West Lynn; res., Nahant, Mass.
Whiteman, Ralph A., Engineering Dept., Pennsylvania Public Service Corp., Johnstown; res., 201 N. 2nd St., Clearfield, Pa.
Widrig, John C., Salesman, A. H. Cox & Co.; res., 1132 8th Ave. West., Seattle, Wash.
Williams, Floyd E., Chief Electrician, Stambaugh Iron Co., Morton Mine; res., 132 Center St., Hibbing, Minn.
Williamson, Harold P., Salesman, Westinghouse Elec. & Mfg. Co., 111 W. Washington St., Chicago, Ill.
Winter, Parker D., Electrical Engineer, Wenatchee Battery & Motor Co., 7 Palouse St., Wenatchee, Wash.
Woidill, Julius A., Jr., Chief Electrical Draftsman, American International Shipbuilding Corp., Hog Island Shipyard, Philadelphia, Pa.
Wolfe, Nelson B., Wolfe & Joyce, 150 Nassau St., New York, N. Y.
*Wood, Harold B., Lineman, The Montana Power Co., Roundup, Montana.
Woodcock, Vincent J., Manager of Electric Fixture & Appliance Dept., Economy Electric Co., 22 Foster St., Worcester, Mass.
Wright, Vernon Radford, Manager, Wenatchee Battery & Motor Co., 7 Palouse St., Wenatchee, Wash.
Young, Dillard M., Erecting Engineer, Westinghouse Elec. & Mfg. Co., 6905 Susquehanna St., Pittsburgh, Pa.
Total 165
*Former enrolled students.

ASSOCIATES RE-ELECTED AUGUST 12, 1920

Fleming, Samuel W., Jr., Member of Firm, Gannett, Seelye & Fleming, 204 Locust St., Harrisburg, Pa.
Garratt, Graham L., Electrical Draftsman, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.
Hund, August, Research Work, 1635 La Loma Ave., Berkeley, Cal.
Morphet, Frank K., Electrician, Vanadium-Alloys Steel Co., Latrobe, Pa.
Muldaur, George B., General Agent, Underwriters Laboratories, 25 City Hall Place, New York, N. Y.
Mulholland, Brendan F., Municipal Engineer, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.
Punga, Franklin, Electrical Engineer, Hamburg Germany.
Radbone, Victor J., Sales Engineer, International General Electric Co., 83 Cannon St., London, E. C. 4, Eng.
Starkey, William C., Chief of Engineering Depts., The Ohio Brass Co., Mansfield, Ohio.

MEMBERS ELECTED AUGUST 12, 1920

Goldschmidt, Charles, Director a la Compagnie Generale d'Enterprises Electriques, 20 rue du Laos, Paris, France.
Johnson, Tomlinson F., Jr., General Electrical Supt., Georgia Railway & Power Co., 452 Electric & Gas Bldg., Atlanta, Ga.
Lynette, Harold A., Commercial Engineer, Westinghouse Elec. & Mfg. Co., 2133 Conway Bldg., Chicago, Ill.
Peck, Henry S., Sales Engineer, A. H. Cox & Co; res., 1612 Boylston Ave., Seattle, Wash.
Shoemaker, Guy T., Electrical Engineer, United Light & Railways Co., 125 W. 3rd St.; res., 916 E., 14th St., Davenport, Iowa.
Tait, Andrew A., Asst. General Master Mechanic, Canadian Car & Foundry Co. Ltd., 120 St. James St., Montreal, Quebec, Can.
Taylor, Claude S., Power Sales Engineer, Electricity Dept.' Shanghai Municipal Council, Shanghai, China.
Taylor, Carl D., Sales Engineer, Westinghouse Electric & Manufacturing Co., Union Bank Bldg., Pittsburgh, Pa.
Weyman, Hugh E., Manager, Levis County Railway, Levis, P. Q., Canada.
White, Bryant, General Supt., Lighting & Power Dept., Roanoke Railway & Electric Co.; Lynchburg Traction & Light Co., Lynchburg, Va.
Wood, Thomas S., Switchboard Engineer, Westinghouse Elec. & Mfg., Co., 133 Candler Bldg., Atlanta, Ga.

FELLOW ELECTED AUGUST 12, 1920

Carter, Thomas, Chief Engineer, with J. H. Holmes & Co.; res., Dene View, Heaton Road, Newcastle-on-Tyne, Eng.

TRANSFERRED TO GRADE OF MEMBER AUGUST 12, 1920

Baker, Frank J., Vice-President, Public Service Co. of Northern Illinois, Chicago, Ill.
Baldwin, Robert L., Electrical & Mechanical Engineer, Burns & McDonnell, Kansas City, Mo.
Barnes, Donald C., Manager, Seattle Division, Puget Sound Power & Light Co., Seattle, Wash.
Barron, Jacob T., General Supt. of Production, Public Service Electric Co., Newark, N. J.
Batcheller, Willis T., Electrical and Mechanical Engineer, Seattle Municipal Light and Power System, Seattle, Wash.
Bennett, Claudius E., Asst. Chief Engineer, Riegos y Fuerza del Ebro, Barcelona, Spain.
Bergstrom, Carl O., Manager, Electrical Dept., B. F. Sturtevant Co., Hyde Park, Mass.
Brill, Oscar C., Office of Chief Engineer, American Telephone & Telegraph Co., New York, N. Y.
Brown, L. E., Superintendent, Springfield Light, Heat & Power Co., Springfield, O.
Durand, William F., Professor of Mechanical Engineering, Stanford University, Stanford University, Cal.
Evans, Clarence T., Development Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
Evans, Llewellyn, Superintendent of Electric Works, City of Tacoma, Tacoma, Wash.
Ferris, Livingston P., Electrical Engineer, Dept. of Development & Research, American Telephone & Telegraph Co., New York, N. Y.
Gaffey, John J., Assistant Engineering Manager, Harry M. Hope Engineering Co., Boston, Mass.
Ghosh, Surendra N., Acting Chief Electrical Engineer, Tata Iron & Steel Co. Ltd., Jamshedpur, India.
Hill, William S., Supt. Light & Power, Springfield Gas & Electric Co., Springfield, Mo.
Hurley, Wallace P., Sales Engineer, Westinghouse Electric & Mfg. Co., New York, N. Y.
Kilner, Ralph H., Commercial Engineer, Westinghouse Electric & Mfg. Co., Chicago, Ill.
Koontz, John A., Jr., Electrical Engineer, Great Western Power Co., San Francisco, Cal.
McAlpine, Dougald D., Contract Engineer, Canadian General Electric Co., Toronto, Ont.
McKenzie, Daniel A., Asst. Engineer, Operating Dept., HydroElectric Power Commission, Toronto, Ont.
Miller, Alvin A., Manager, Power & Railway Divisions, Westinghouse Elec. & Mfg. Co., Seattle, Wash.
Oetting, O. W. A., Chief Engineer, Willard Storage Battery Co., Cleveland, O.
Pace, Gordon, District Operating Engineer, Hydro Electric Power Commission of Ontario, Toronto, Ont.
Pearce, Walter C., Supt., Electric Dept., Syracuse Lighting Co., Syracuse, N. Y.
Prindle, Edwin J., Senior Partner, Prindle, Wright & Small, New York, N. Y.
Read, Ernest K., Circuit Breaker Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
Robley, Roy R., Operating Engineer, Portland Railway, Light & Power Co., Portland, Ore.

Smith, Harold L., Designing Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.
Van Horn, Irving H., Physicist, Lamp Development Lab., National Lamp Works of General Electric Co., Nela Park, Cleveland, O.
Warner, Russell G., Instructor in Electrical Engineering, Yale University, New Haven, Conn.
Westman, Adolf J., Electrical Engineer, Montreal Tramways Co., Montreal, Canada
Zima, Ludwig A., Assistant Cable Engineer, Interborough Rapid Transit Co., New York, N. Y.

TRANSFERRED TO GRADE OF FELLOW AUGUST 12, 1920

Beeuwkes, Reinier, Electrical Engineer, Chicago, Milwaukee & St. Paul R. R. Co., Seattle, Wash.
Fernow, Bernhard E., Jr., Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
Morton, Robert B., Electrical Engineer with Toltz, King & Day, St. Paul, Minn.
Murphy, George R., Manager, Pacific District, Electric Storage Battery Co., San Francisco, Cal.
Pierce, Arthur G., Manager, Central District, Cutler-Hammer Mfg. Co., Pittsburgh, Pa.
Rice, Ralph H., Principal Assistant Engineer, Board of Supervising Engineers, Chicago, Ill.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held on July 26 and August 9, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

Recommended by Board of Examiners July 26, 1920 To Grade of Fellow

Lundy, Ayres D., Member of Firm, Sargent & Lundy, Chicago, Ill.
Stevens, William C., Sales Manager, The Cutler-Hammer Mfg. Co., Milwaukee, Wis.

To Grade of Member

Anderson, Stewart W., Adjunct Prof. of Elec. Engg., Virginia Military Institute, Lexington, Va.
Andrews, Samuel W., Asst. Plant Engr., Niagara Power Development, Hydro-electric Power Commission, Niagara Falls, Ont.
Blalock, Grover C., Instructor in Electrical Engineering, Purdue University, Lafayette, Ind.
Boyajian, Aram, Development & Research Engineer, General Electric Co., Pittsfield, Mass.
Code, Elden S., Sales Engineer & Switchboard Designer, Westinghouse Elec. & Mfg. Co., Seattle, Wash.
Costello, W. H., Sales Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
Fawcett, Charles DeVan, Asst. Prof. of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa.
Friday, Ellsworth C., District Manager, Corliss Carbon Company, Chicago, Ill.
Garlington, A. C., Supt. Construction & Maintenance, Elec. Div., Panama Canal, Balboa, C. Z.
Goetzenberger, Ralph L., Major, Ordnance Dept., U. S. Army, Frankford Arsenal, Philadelphia, Pa.
Hail, Joseph C., Electrical-Engineer-in-Charge, Dept. of Electricity, City of Chicago, Ill.
Knost, Chas. P., Salesman, Westinghouse Elec. & Mfg. Co., New Orleans, La.
Lund, Charles A., Distribution Engineer, Tacoma Light Dept., Tacoma, Wash.
McGrath, William H., Vice-President, Puget Sound Power & Light Co., Seattle, Wash.
Matthews, Howard D., Prof. of Elec. Machine Design, School of Engineering of Milwaukee, Milwaukee, Wis.
Mullen, Clyde A., Engineer of Tests, The Ohio Service Company, Coshocton, O.
Newton, John M., Chief Engineer, The Roland T. Oakes Company, Holyoke, Mass.
Olsen, Valdemar, Meter Engineer, Shanghai Municipal Council, Electricity Dept., Shanghai, China.
Oster, Eugene, Electrical & Mechanical Director, The Ault & Wiborg Co., Cincinnati, Ohio.
Owens, James W., Welding Aid & Asst. Shop Supt., U. S. Navy Yard, Norfolk, Va.
Rich, Edward P., Consulting Engineer, Chicago, Ill.
Rowe, E. C., Chief Draftsman, Commonwealth Edison Company, Chicago, Ill.
Sears, George C., Supt., White River Division, Puget Sound Power & Light Co., Dieringer, Wash.
Traver, O. C., Supervising Designing Engineer, Switchboard Dept., General Electric Co., Schenectady, N. Y.
Wegg, David S., Jr., Sales Engineer, Allis-Chalmers Mfg. Co., Chicago, Ill.
Wentworth, Herbert H., Industrial & Railway Motor Engg. Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Recommended by Board of Examiners August 9, 1920 To Grade of Member

Beird, Hobart B., Electrical Engineer, United Gas & Electric Engineering Corp., New York, N. Y.
Baldwin, John R., Electrical Engineer, Republic Flow Meters Co., Chicago, Ill.
Dustin, Fred G., President, Standard Electric Service Co., Minneapolis, Minn.
Goddard, Ralph W., Dean of Engineering, Professor of Electrical Engineering, New Mexico College of Agriculture & Mechanic Arts, State College, N. M.
McBrian, Edward W., Mechanical Engineer, Fox Bros. & Co., New York, N. Y.
Parker, Samuel R., Engineer of Plant, Saskatchewan Government Telephones, Regina, Sask.
Radbone, Victor J., Sales Engineer, Int'l. General Electric Co., London, England.
Shoemaker, Joseph J., Supt. of Public Utilities, Town of Sibley, Sibley, Ia.
Tolman, Clarence M., Moose Mountain, Ltd., Sellwood, Ontario
Wilson, N. P., District Service Manager, Westinghouse Elec. & Mfg. Co., Seattle, Wash.

APPLICATION FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member, objecting to the election of any of these candidates should so inform the Secretary before September 30, 1920.

Adams, Willard C., (Member), Chicago, Ill.
Alexander, Lowell M., Cincinnati, Ohio
Alexander, Roland B., Akron, Ohio
Alt, Milo S., Cedar Rapids, Ia.
Ames, Norman B., Akron, Ohio
Ammann, Philip G., New York, N. Y.
Anton, George, Lannett, Ala.
Barlow, Godfrey F., Toronto, Ont.
Beaudry, J. Armand, Worcester, Mass.
Beckenbach, Francis H., Schenectady, N. Y.
Bertrand, Philip A., (Member), Aberdeen, Wash.
Brown, Michael J., New York, N. Y.
Brownstead, John P., Ashland, Ky.
Budd, Chester E., New York, N. Y.
Butler, W. H., (Fellow), Philadelphia, Pa.
Cole, George H., Akron, Ohio
Cox, George R., New York, N. Y.
Daymude, John F., Cleveland, Ohio
de Forest, Charles S., New Haven, Conn.
Dyer, Franklin M., Boston, Mass.
Eldredge, William S., Chicago, Ill.
Evans, Earl R., Washington, D. C.
Eyster, James A., Waterbury, Conn.
Ferris, Bentley R., Akron, Ohio
Fielder, George M., New York, N. Y.
Green, Stanley S., W. Lafayette, Ind.
Henningsen, Earle S., Schenectady, N. Y.
Hefner, W. Albert, New York, N. Y.
Hempton, Frank, Gallup, New Mexico
Jones, David Clarence, Jr., Atlanta, Ga.

Key, Antonio E. Toro, Washington, D. C.
Kramer, Charles H., Cincinnati, Ohio
Krause, Joseph F., Milwaukee, Wis.
Leach, George M., Atlantic City, N. J.
Lewis, Ralph, New York, N. Y.
Malkin, Louis, Brooklyn, N. Y.
Matsuda, Saichi, E. Pittsburgh, Pa.
McGee, Robert F., Raleigh, N. C.
Miller, Andrew McR., Paris Island, S. C.
Miller, W. Webster, (Member), New York, N. Y.
Milliken, Earle L., Woonsocket, R. I.
Moore, Louis D., St. Louis, Mo.
Nakamura, Ichiro, New York, N. Y.
Peck, A. D., (Fellow), Beverly, Mass.
Piasecki, Harry A., Buffalo, N. Y.
Prack, J. Bernard, St. Louis, Mo.
Quinn, R. C., Atlanta, Ga.
Ryan, James A., Brooklyn, N. Y.
Schrumm, Jewett F., Waterbury Conn.
Seldin, William, Coney Island, N. Y.
Schilling, Eugene W., Akron, Ohio
Sitterle, Emil, Cleveland, Ohio
Smith, B. F., Atlanta, Ga.
Spilver, Fred W., Los Angeles, Cal.
Tadlock, J. H., Schenectady, N. Y.
Tonnesen, Sigvald, Hyde Park, Boston, Mass.
Weaver, George S., St. Louis, Mo.
White, E. Sherman, Long Island City, N. Y.
Wolfe, John F., Lancaster, Pa.
Wolle, James L., Philadelphia, Pa.
Total 60.

Foreign

Buttner, Harold H., Bordeaux, France
Doi, Masaji, Fukuokaken, Japan
Hattori, Katsuo, Kanasugi, Shiba, Tokio, Japan
Hayashi, Seiichiro, Marunouchi, Tokio, Japan
Horley, R. E. (Member), Southampton, England
Imai, Masakazu, Darien, Manchuria
Isono, Tatsuichiro, Kanasugi, Shiba, Tokio, Japan
Jones, Roy Stuart, Rubgy, Eng.
Komaru, Toda, Kobe, Japan
List, Vladimir, Brni, Czechoslovakia
Nakano, Yoshio, Muronan, Japan
Navarro, Justo Lopez, Manila, P. I.
Okada, Hisashi, Kanasugi, Shiba, Tokyo, Japan
Tojo, Kiichi, Kanasugi, Shiba, Tokyo, Japan
Trewman, Harry F., Woolwich, London, Eng.
Total 15.

STUDENTS ENROLLED AUGUST 12, 1920

11656 Lorenzo, A. de la L., School of Engg. of Milwaukeee
11657 Havlick, Joseph, School of Engineering of Milwaukee
11658 Fordham, Lyle, School of Engineering of Milwaukee
11659 Scudder, Felix W., University of Colorado
11660 Kerr, Francis, P., University of Colorado
11661 Clarke, Thomas H., University of Colorado
11662 Hutchinson, Halbert, Swarthmore College
11663 Kidd, Walter J., Pennsylvania State College
11664 Scott, Richard C., University of Michigan
11665 Crapo, Frederick M., Mass. Institute of Technology
11666 Martin, John J., Carnegie Institute of Technology
11667 Casey, Harry J., Johns Hopkins University
11668 Kemmeter, Bernard G., Tri-State College
11669 Glacy, Edward W., Tri-State College
11670 Bailey, Herbert R., Tri-State College
11671 Frazee, Floyd LeR., Armour Inst. of Technology
11672 Strong, Lewis B., Pratt Institute
11673 Seitanides, George B., Robert College
11674 Selpien, Carl W. H., Ohio Northern University
11675 Arbuckle, James S., McGill University
11676 Graf, Frank G., Pratt Institute
11677 Walmsley, George, Mass. Institute of Technology
11678 Huse, Walter D., New Hampshire College
11679 Thompson, Trevo C., McGill University
11680 Morgan, Robert B., Sheffield Scientific School
11681 Hendy, John W., Pratt Institute
11682 Ruge, Henry P., Lewis Institute
11683 Albert, Rudolph M., Columbia University
Total 28.

OFFICERS of A. I. E. E. 1920-1921

PRESIDENT.

(Term Expires July 31, 1921)

A. W. BERRESFORD

JUNIOR PAST-PRESIDENTS.

(Term expires July 31, 1921)
COMFORT A. ADAMS

(Term expires July 31, 1922)
CALVERT TOWNLEY

VICE-PRESIDENTS.

(Terms expire July 31, 1921)

CHARLES S. RUFFNER, C. E. MAGNUSSON
CHARLES ROBBINS, E. H. MARTINDALE
L. T. ROBINSON, C. S. McDOWELL

MANAGERS.

(Terms expire July 31, 1921)
WALTER A. HALL
WILLIAM A. DEL MAR
WILFRED SYKES

(Terms expire July 31, 1922)
WALTER I. SLICHTER
G. FACCIOLI
FRANK D. NEWBURY

(Terms expire July 31, 1923)
L. E. IMLAY
F. F. FOWLE
L. F. MOREHOUSE

(Terms expire July 31, 1924)
HAROLD B. SMITH
JAMES F. LINCOLN
E. B. CRAFT

TREASURER / **SECRETARY**

(Term expires July 31, 1921)

GEORGE A. HAMILTON / F. L. HUTCHINSON

HONORARY SECRETARY
RALPH W. POPE

DIRECTOR OF THE LIBRARY
HARRISON W. CRAVER

GENERAL COUNSEL

PARKER and AARON,
66 Broad Street, New York.

PAST PRESIDENTS—1884-1920

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
T. Commerford Martin, 1887-8.
Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
Schuyler Skaats Wheeler, 1905-6.
Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Kewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.
Calvert Townley, 1919-20.

*Deceased.

Economic Study of Secondary Distribution

BY P. O. REYNEAU
AND
HOWARD P. SEELYE

Both of the Detroit Edison Company.

Introduction

In working toward the efficient and economical design of the central station system as a whole no link in the chain connecting the consumer with the coal pile may be overlooked. The ultimate purpose of all study in this direction is to enable energy to be delivered to the customer at the least possible cost per unit, while at the same time good service is maintained. To this purpose considerable attention has been paid to generating plant, transmission lines and substations, but on the final link before reaching the customer—the distribution lines—the tendency has been to apply "rule of thumb" methods and "experience" only to the layouts. When it is considered that even in a well designed system the investment in distribution lines will often be from one-fifth to one-fourth of the total investment on the system and that the energy losses on these lines will be equal to or somewhat more than one-half of the total loss between the generator and the customer, it may be expected that a study of the economical design of distribution lines will be found of great profit. Such has been found to be the case, and the results of the study of secondary distribution described in this paper have been already applied to good advantage in the layout of such lines.

There are several conditions pertaining to the secondary system which make the careful layout of such a system especially important. The number of transformer installations is so large and the lines spread over so great an area that constant or even frequent inspection is impossible. The load is subject to irregular increases. In districts which are newly built up, new services are constantly being added. In old districts, new appliances are being purchased and the load on old services thereby increased. On this account any design must be made to cover a period of years and the increase in load for that period estimated from past experience. On the other hand, care must be taken not to install too much capacity and thereby increase the cost beyond the limits of economy. The problem must be carefully studied to obtain the balance between low cost and good service for any particular case.

In general the problems most often encountered are of the following types:

1. New lines in thinly populated districts where the load will probably build up rapidly.
2. Old lines in residence districts well built up where revision is necessary to care for a slowly increasing load.
3. Old lines in districts with heavy, increasing load such as business districts.
4. Exceptional installations such as for permanent loads with no increase or for a decreasing load.

In attacking such a problem we can often determine from tests and from past experience what the density of the loading is and how it will increase for some years in advance. We are usually limited to certain stock sizes of transformer and of wire, on any system, due to practical considerations of manufacturing and stock keeping. The problem then is to determine the proper combination of wire, transformer and transformer spacing in order to give good conditions of operation and also to show the least cost per year for the load densities expected during the period of time under consideration.

The purpose of this paper then is to study from an economical viewpoint the conditions generally met with in secondary distribution and to furnish as far as possible guidance for the designer to aid him in any particular problem with which he has to deal. It is clearly understood that no definite rules can be established which will fit all conditions. The variations in the problem are too many. The most that can be done is to furnish means for readily discovering the limitations of any problem and of proceeding within these limitations to the most economical design.

The study has been carried forward from three different angles. First from the theoretical; second from a semi-practical, that is by adopting certain standards and studying their behavior; third from

a purely practical, giving the designer data on the operation of various transformers and wire sizes under the conditions ordinarily encountered in practise.

In all this discussion it has been assumed that the loading is such that it may be considered as uniformly distributed along the line. The unit used is called load density, given in kilowatts per thousand feet. The line is assumed to be three-wire secondary, spaced 42 in. between outside wires. The cost of right-of-way, poles, cross arms and insulators is not included in any of the computations as it is assumed this would be the same under any given condition. Also the difference in length of primary for different transformer spacings is not considered. In actual design under known conditions a correction should be made for this. The loading conditions are taken as those of residence lighting districts although the same methods could be adapted to any other conditions of loading if its characteristics were known. Transformers are assumed to be in the center of the secondary served, feeding both ways. The symbols used and all the mathematical calculations will be found in Appendix A and B. Only the discussion will be presented here.

Discussion of Methods Used in Deriving Equations and Their Application

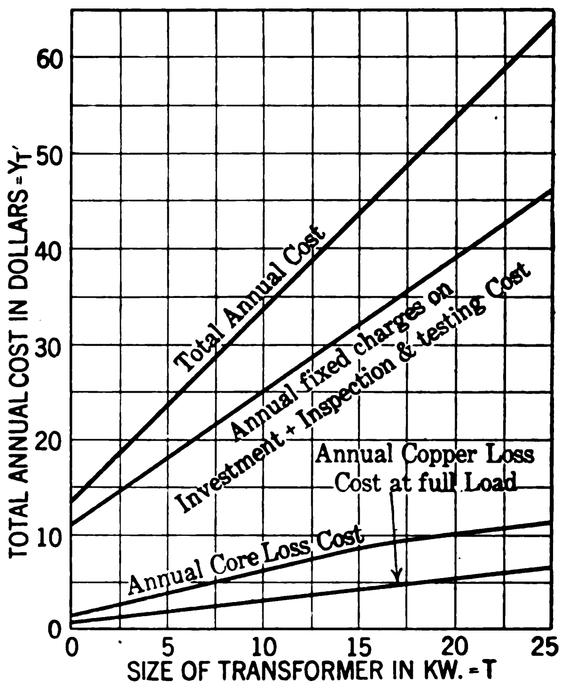
Theoretical. In the theoretical discussion ideal conditions are assumed which will rarely if ever be met with in practise, but it can be shown by a study of the results how they may be applied to practical conditions. These assumptions are that the line is indefinite in length so that the transformers may be placed at any exactly determined spacing and that the spacing will change with the load; that the transformer is always of a size just equal to the load to be carrried, that is equal to the load density at peak load times the spacing; that the wire may be of any cross-sectional area and vary with the load. Such a condition could only be obtained in a case where the load showed only seasonal variations and no yearly increase. However, in practise we usually design for a certain period at the end of which it is assumed the load density will be a certain amount.

The general method has been to obtain an expression for the annual cost per 1000 feet of line and to determine, by finding the first derivative and setting it equal to 0, the condition under which this annual cost is a minimum. This is the most economical condition.

Annual Cost of Secondary Distribution. The general equation for the annual cost is first obtained as follows: (Total annual cost per 1000 ft.) = (Annual Cost on transformers per 1000 ft.) + (Annual Cost on line per 1000 ft.)

$$Y = Y_t + Y_L$$

The annual cost on transformers must include interest, depreciation, insurance and taxes on the investment represented by the transformer in place. This investment is made up of the purchase price, plus freight and warehouse charges, plus cost of installation including lightning arresters, etc. It also includes the cost per year of inspecting and testing and the cost of energy losses. The core loss is practically a constant quantity for 24 hours per day throughout the year. The copper loss on the other hand depends on the load. If the characteristic variation of this load from hour to hour, day to day and month to month is known, the average loss per day can be determined in terms of the year's peak load. In this case the peak load is assumed to be just equal to the capacity



Curve No. 1—Annual Charges on Transformers
Transformers assumed to be fully loaded at yearly peak load.
Curve of total cost approximates equation
$Y_T' = K_1 + K_2 T$

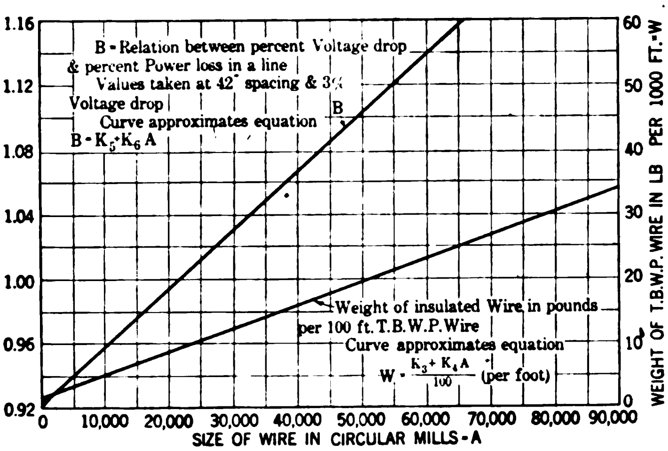
of the transformer. The cost of energy at the transformer must also be carefully determined. The cost for copper loss will be considerably higher than that for core loss on account of the lower load factor. The sum of all these items makes up the annual cost on a transformer.

It was found that if the value of the transformer annual cost is plotted against the transformer size that the curve for values between 0 and 25 kw. may be approximated by a straight line of the formula $Y_T, = K_1 + K_2 T$, T being the transformer size and K_1 and K_2 constants to be determined for any particular combination of transformer cost, energy cost, etc. (See curve No. 1.) This becomes $Y_T = \frac{1000}{S}(K_1 + K_2 T)$ per 1000 ft., where S is the length of secondary belonging to any one transformer or the distance between transformers where banked.

The annual cost on the line includes interest, depreciation and taxes on the investment cost of the

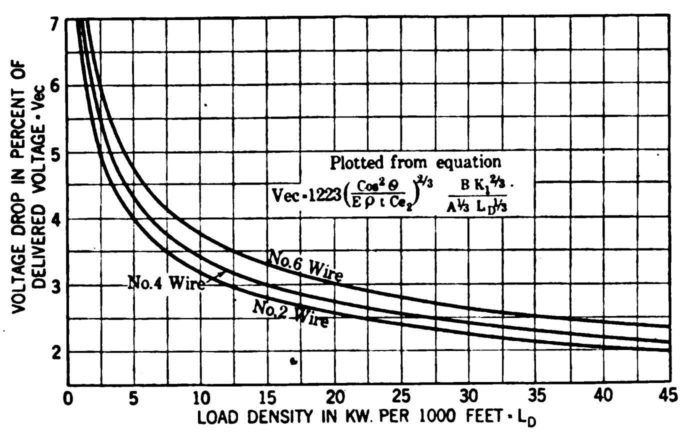
wire in place, including purchase price and cost of installation, also the cost of annual energy loss due to resistance. The copper loss is arrived at by the same method as the copper loss on the transformer, that is by use of the equivalent average number of hours per day at full load or equivalent hours.

The total annual cost per 1000 ft. of installation is now obtained by adding these two quantities, annual



Curves No. 2 and 3

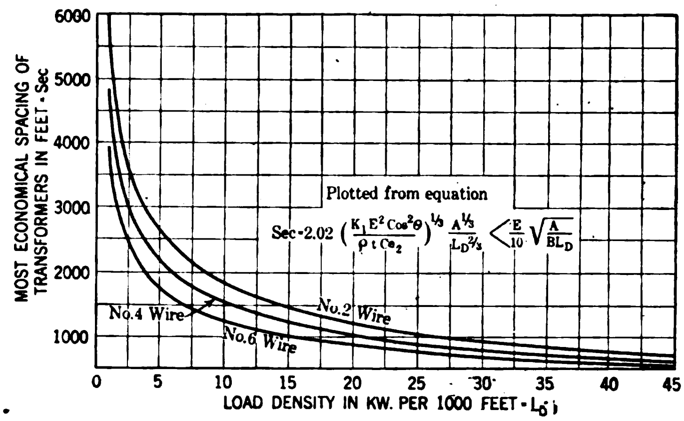
cost of transformers and annual cost on line, and the equation obtained as shown in equation (4)—(Appendix B) for Y in terms of S (length of secondary), L_D (load density), A and W (cross-sectional area and weight per foot of wire) and various constants to be determined by local conditions.



Curve No. 4—Most Economical Voltage Drop in Per Cent of Delivered Voltage

Load Uniformly distributed—Transformer size just equal to load.

Most Economical Voltage Drop. One of the most important controlling factors in determining the length of a secondary or the spacing of transformers is the maximum allowable voltage drop. It has usually been considered that the most economical condition of operation would be with a voltage drop higher than would be allowable for good service. In our case 3 per cent drop has been considered the limiting value, as luminosity curves for Mazda lamps show a reduction as high as 18 per cent with 5 per cent voltage drop while 3 per cent shows over 10 per cent reduction. Considering the voltage loss in the service drops which cannot be figured closely on account of variable conditions and the fact that the load is not absolutely uniformly distributed, 3 per cent is considered the



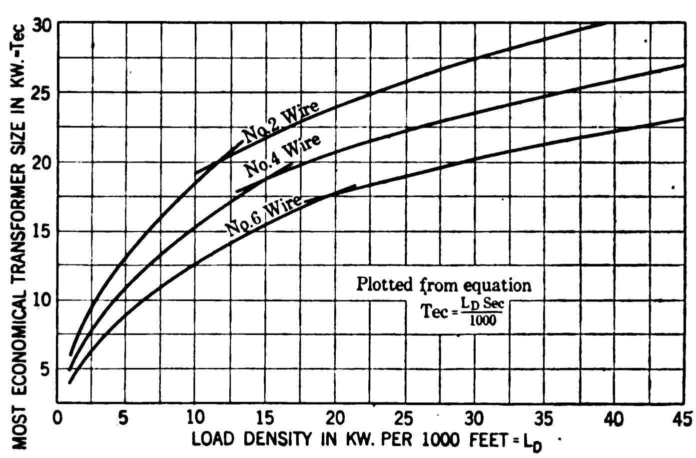
Curve No. 5—Most Economical Spacing of Transformers

Limited by a maximum allowable voltage drop of 3 per cent. Load uniformly distributed—Transformer size just equal to load

highest value commensurate with good operation. It must be determined, then, if under certain conditions, a smaller voltage drop than this will be more economical.

The expression for Y can be reduced to an equation in terms of L_D (load density), A. (cross-sectional area of wire), and V (per cent voltage drop). If this is then differentiated with respect to V and the first derivative set equal to 0, an expression is obtained for the most economical voltage drop in terms of wire size and load density. Equation (6). (Appendix B).

By assuming values for the constants to fit partic-



Curve No. 6—Most Economical Transformer Size

Being just equal to the load at the most economical spacing

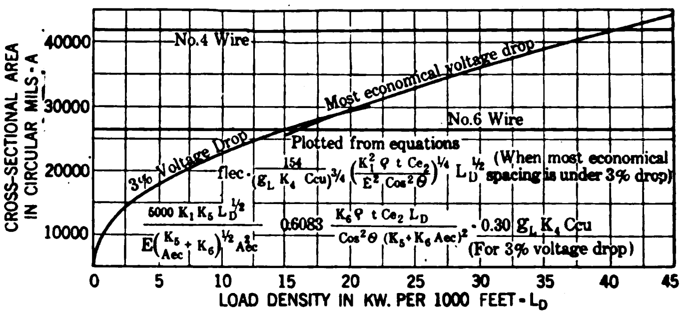
ular conditions this expression for V can be plotted against load density for various standard wire sizes. These curves show that, as load density increases, the most economical voltage drop decreases and under the conditions assumed in the curves here plotted, the

most economical voltage drop falls below 3 per cent at load densities which are often encountered with such loads, see curve No. 4.

Most Economical Transformer Spacing. In a similar manner it is possible to treat the question of length of secondary or transformer spacing. Equation (**4**) may be differentiated with respect to S (the transformer spacing). The first derivative is equated to 0 and we have the expression for the most economical spacing, equation (**7**). The transformer spacing however must be governed, for the smaller load densities, by the limiting voltage drop—taken here as 3 per cent. Hence equation (**8**) is derived which gives the spacing for a maximum voltage drop of 3 per cent. If now the constants are evaluated these curves may be plotted for various sizes of wire, using, for any particular load density, the equation which shows the shortest spacing. We obtain the set of curves No. 5 giving the transformer spacing which will give, with any wire size, the greatest economy, providing good operating conditions are maintained by having no voltage drop greater than 3 per cent.

Most Economical Transformer Size. It is a simple matter with these data at hand to derive the curves showing the most economical transformer size for any load density, providing the transformers are spaced most economically. Since it was assumed in the beginning that the transformer would be just large enough to carry the load, $T = L_D \frac{S}{1000}$ where S is the value taken from the curves for most economical spacing. This is the most economical size for any load since the annual charge on the investment represented by the transformer is a much greater proportion of the total annual charge than the cost of energy losses. Therefore the use of a larger transformer, even though under-loaded, would be more costly.

Most Economical Wire Size. It is now possible to attack the problem of the most economical size of wire for any load density. We will assume that it is feasible to use the most economical transformer size at its most economical spacing for any load density, modified by the limiting 3 per cent voltage drop requirement. Then if we substitute in our original equation, equation (**4**), the expressions for S used in plotting the curves for most economical spacing and for spacing limited by 3 per cent drop in voltage, we obtain two expressions for the annual cost per 1000 ft. in terms of load density and cross-sectional area of wire (A). Here it is necessary to introduce two approximations. The weight per foot of wire (w) enters the equation, also the quantity B which is the constant relation between per cent voltage drop and per cent power loss for any size of wire. It is found by plotting values of w for standard sizes of wire of the range of sizes which would be used in secondaries that the expression $w = K_3 + K_4 A$ is a very close approximation, K_3 and K_4 being constants (see curve No. 2). Also it is found that the value of B for any size of wire may be approximated very closely by the straight line function $B = K_5 + K_6 A$, where K_5 and K_6 are constants (see curve No. 3). These must be derived from the particular values of B which apply to the conditions being studied since these values vary for different spacings between wires. Substituting these expressions in the equations referred to above we obtain the two general expressions for annual cost per 1000 ft. in terms of wire size for maximum economy of transformer spacing and for 3 per cent voltage drop equations (**10**) and (**12**). These are now differentiated with respect to A and the equations (**11**) and (**13**) are obtained between the most economical wire size and the load density for most economical spacing and for 3 per cent voltage drop. The constants were evaluated and these curves plotted (No. 7), the 3 per cent curve for low load densities and the maximum economy curve



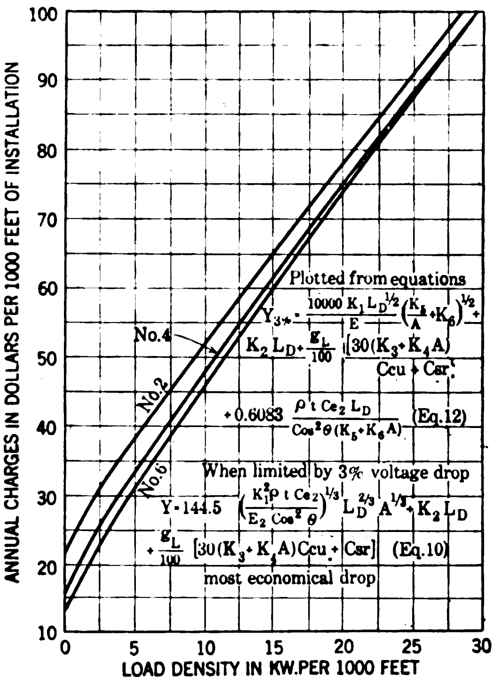
Curve No. 7—Most Economical Wire Size

Transformer size assumed just equal to load at most economical spacing limited by 3 per cent voltage drop

for high loading. They furnish a graphic representation of the most economical size of wire to use under any load density providing ideal conditions obtain in the way of transformer size and spacing.

Purpose of Theoretical Curves. At first glance it may appear as if these curves being obtained on the basis of such theoretical assumptions could have very little practical value. However, when attacking a practical problem of this nature the data from these curves may be used as the basis upon which to start the calculations of annual costs under operating conditions. If for example the present load density and the load density which is to be expected at some certain future time are known, by going to the theoretical curves we may determine (a) whether the voltage drop is to be limited by the 3 per cent maximum, (b) what would be the most economical conditions of transformer size and spacing for present operation and for operation at that future time, and (c) what standard size of wire will be most economical over the period. The curve for the most economical wire size covers, for each standard size, such a range of load densities that we should be able at once to select our wire size without further computation. Having determined this and

knowing what stock sizes of transformers and practical spacings come the nearest to fitting the ideal conditions over the period under consideration, we can then investigate, as will be shown later, the comparative economy of such various methods of installation as could be used in this particular case. In other words



CURVE No. 8—SHOWING COMPARATIVE ECONOMY OF VARIOUS WIRE SIZES IN SECONDARY INSTALLATIONS

Transformer sizes and spacings assumed to be those most theoretically economical, limited by 3 per cent maximum voltage drop.
Annual cost includes line and transformers.

these theoretical curves give certain limitations on which we may proceed to further more practical investigation.

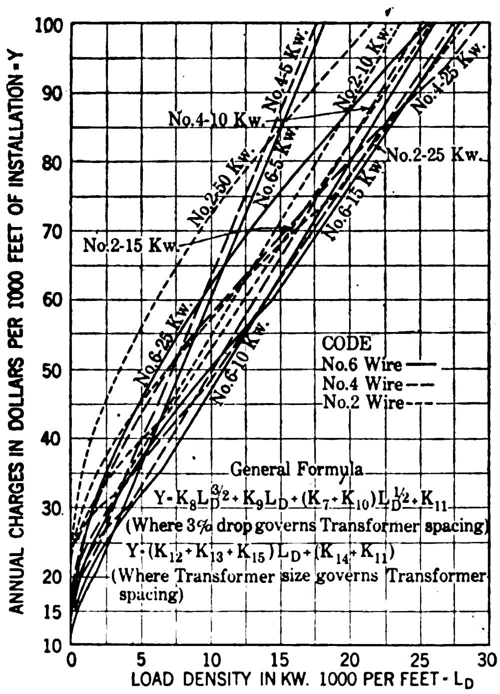
SEMI-PRACTICAL. In order to present our results in a little more concrete and practical form and to show the exact comparative economy between various types of installation, especially with respect to the size of wire to be used, a series of curves was developed showing the exact annual cost under various conditions. These are called the semi-practical curves. Curves No. 8 and No. 9.

Annual Cost of Standard Wire Sizes Working under Ideal Conditions. The first condition was assumed to be that in which the most economical size of transformer could be used, spaced the most economically or, where necessary, for 3 per cent maximum voltage drop. A curve was plotted for each of the three standard sizes of wire No. 6, No. 4 and No. 2, showing the annual cost at various load densities, (see curve No. 8). This is, in reality, simply plotting equations (**10**) and (**12**) as developed above.

Annual Costs per 1000 ft. of Installation for any Combination of Standard Sizes of Wire and Transformers. As the next step in proceeding from the general problem to the concrete example various combinations of standard sizes of transformers with standard sizes of wire were assumed and curves developed showing the annual cost of each of these combinations at various load densities. The transformer spacing was still assumed to be always the theoretically best spacing for each particular load. This enables us to compare for example the economy of a 10-kw. transformer and No. 4 wire with that of a 15-kw. and No. 6 wire at any load density.

The method of developing these curves has some points of interest although the equations are merely variations of our general equation for annual cost per 1000 ft. It is seen that for any size of transformer, as the load density increases a certain point is reached where the spacing is no longer governed by the allowable voltage drop but by the size of the transformer itself. Hence each curve will consist of two parts, the lower where the voltage drop governs the spacing, the excess transformer capacity is provided, the upper where the transformer size governs the spacing and the voltage drop is less than the allowable. The total annual cost is made up of five items.

1. Transformer core loss.
2. Transformer copper loss.
3. Copper loss on the line itself.



CURVE No. 9—SHOWING COMPARATIVE ECONOMY OF VARIOUS COMBINATIONS OF SECONDARY INSTALLATIONS

Load uniformly distributed.
Voltage drop most economical—maximum 3 per cent.

4. Fixed charges on the transformer (interest, depreciation, taxes, inspecting, tests, etc.)
5. Fixed charges on the line. (Interest and depreciation).

Each of these five elements was analyzed as to constants and variables, considering the load density L_D

as the chief variable, and the transformer and wire sizes constant for any given condition. It was found that the equations took the following form:

$Y = K_8 L_D^{3/2} + K_9 L_D + (K_7 + K_{10}) L_D^{1/2} + K_{11}$

when the voltage drop and wire size govern, and

$Y = (K_{12} + K_{13} + K_{15}) L_D + (K_{11} + K_{14})$

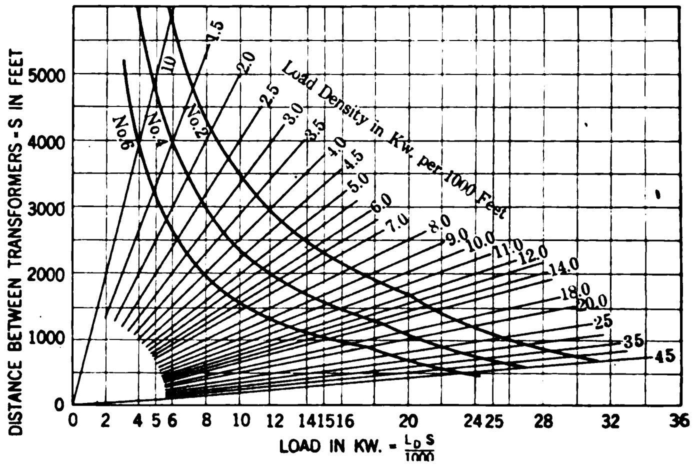
when transformer size governs.

The first is an equation of a third degree curve in $L_D^{1/2}$ breaking into a straight line (the second equation) at the critical point where the spacing for 3 per cent drop fully loads the transformer. The equation for each constant was then developed and evaluated for each combination of wire and transformer. The results were then plotted as shown in curve No. 9. The detailed derivation of these equations and constants has been omitted from the appendix as these are of less relative importance than the others given.

Purpose of Semi-Practical Curves. These semi-practical curves, although reducing the variable elements, still retain enough of the ideal condition so that they cannot be used as an absolute criterion but merely as a guide. They do show however, concretely, the relative economy of the various standard sizes of wire when used under the most favorable conditions and this may be taken as a guide to their comparative behavior under all conditions. The second set of curves also shows concretely the relative economy of the various transformer sizes with any one size of wire as well as the relative economy of various sizes of wire with any size of transformer. This comparison of economy is valuable in showing the exact amount by which the annual cost of one installation is greater or less than another. It often occurs that where the difference in cost is not great, other advantages are sufficient to more than offset it and lead to the choice of the more costly. The spacing of transformers is here considered to be the maximum allowable throughout, with the transformer carrying its maximum allowable load. This limits the general application of these curves in practise and hence like the first series they are chiefly useful in establishing limits and as a basis for the design.

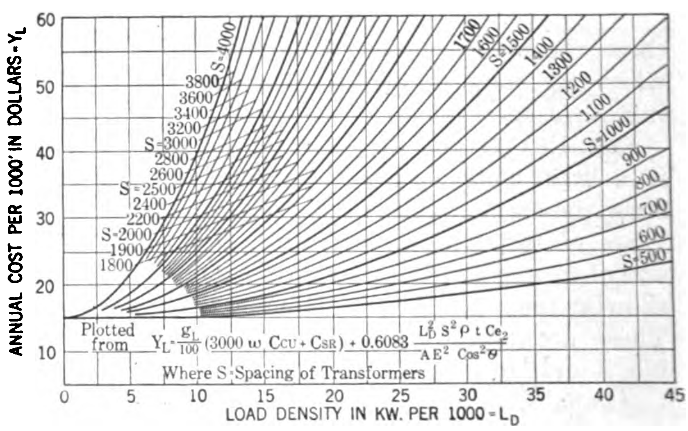
PRACTICAL. We now come to the development of the curves which the designer may use in testing the economy of any design and thereby choose the most economical from several alternatives. Here no "most economical" conditions need be assumed. The curves simply represent annual costs as they occur under any condition which may be encountered.

Load Curves for Secondaries. The first curve is a development from the two theoretical curves, the most economical transformer spacing and most economical transformer size. By plotting the transformer size against the spacing we obtain for each size of wire a curve showing the most economical spacing or the spacing limited by 3 per cent voltage drop for any total load on the transformer (see curve No. 10). By drawing diagonal lines, one for each load density desired, we can now show for any particular load density, the maximum economical spacing, and the minimum transformer size with that density and spacing. This curve merely simplifies the former two and serves the same purpose, not introducing any new principles. It is evident that any point below the curve will indicate a drop less than the value used on



CURVE NO. 10—LOAD CURVES FOR SECONDARIES
Three-wire secondaries—244/122 volts at customer.
Most economical transformer spacing limited by 3 per cent voltage drop.
Power factor 95 per cent —Load uniformly distributed—42-in. spacing between outside wires.

the curve. This curve is of use in determining what alternative designs may be feasible with any load and standard equipment and what changes may be made to care for an increase.

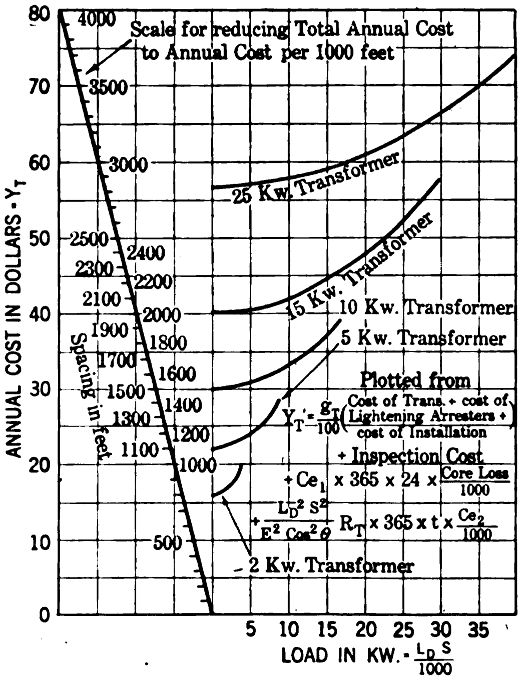


CURVE NO. 11—LINE COST CURVES
Annual cost per 1000 ft. of three No. 4 secondaries including fixed charges and cost of lost energy.

Line Cost Curves. The equation for annual charges on the line, (equation (3) Appendix B) was next developed. All constants were evaluated and a curve plotted for each desired spacing—100-ft. intervals were used—showing the annual charges per 1000 ft. in terms of the load density for each standard size of wire. (See curve No. 11 for No. 4 wire.)

Transformer Cost Curves. The third set of curves shows the annual cost on the transformer for any

loading, (see curve No. 12). This of course is equal to the fixed charges, plus the core loss cost which is constant for all loads, plus the copper loss cost which varies as the square of the load. The equation for each of the standard sizes of transformers, 2, 5, 10, 15 and 25 was developed and plotted. Since this curve shows total annual cost on a transformer and not cost per 1000 ft. of installation a scale was added on the diagonal at the left by use of which, with a pair of triangles, the cost per 1000 ft. may be obtained by the principle of similar triangles. Draw a line from the total cost obtained to the spacing as shown on the diagonal scale and a parallel through 1000 ft. will indicate the annual cost per 1000 ft. on the vertical scale. (See Appendix B for illustration.)



Curve No. 12—Transformer Cost Curves

Total annual cost on various sizes of transformers under various loads. Includes fixed charges and cost of energy losses.

Cost of Replacing Transformers. Two more items of cost are of interest to the designer and these are arbitrarily fixed by local conditions, the cost of changing the size of transformers in the same location and the cost of changing the location of a transformer. These will be practically constant for all sizes and may be determined in any case from local cost records.

Application of Practical Curves. We are now ready to furnish the designer with the information necessary to test the relative economy of any two alternative designs. He first determines his wire size from a study of the theoretical and semi-practical curves. Then, going to the load curves he may determine his alternatives in transformer size and spacing. Assume that conditions point to the alternative of installing 10-kw. transformers at a long spacing, changing to 15 kw. at a shorter spacing after a certain period of years, or of installing the 10 kw. at the shorter spacing now and merely changing sizes at that time. From our curves the exact cost per 1000 ft. for each year under consideration may be obtained by using the correct loading and spacing and, at the proper time, adding the cost of either changing location or changing size. The total of the annual costs for each design gives the total cost over the period under consideration and a comparison of the totals shows exactly the relative economy of the designs over the whole period. These curves may be applied to any such problem since they are based not on the assumption of ideal conditions but cover any actual condition which might occur in practise. They can be used in cases where the transformer spacing cannot be uniform on account of local conditions of pole spacing, secondary length, and street and alley arrangement, a very usual case. When there is doubt about the wire size a study of the various possible combinations making use of these curves will soon determine the size for greatest economy. Similar curves can also be developed to suit other classes of problems such as concentrated loads, loads with characteristic variations different from those of the residence load used here, as in business districts, power loads, etc.

Example of Application of Practical Curves. A concrete example of the use of the above curves may be helpful. Assume that tests on a district show a load density of 8 kw. per 1000 feet, with No. 4 secondary wire already in place. Our load curves show for that loading and size of wire, 12.8 kw. load at 1800-ft. spacing to keep within 3 per cent drop in voltage. We wish to provide for an increase in load which we will estimate may go to 15 kw. per 1000 ft. in six years. For the present a 10-kw. transformer spaced at 1400 ft. would care for the load while at 15 kw. per 1000 feet there would be required a 15-kw. transformer at 1000-ft. spacing or a 25-kw. at 1200 ft. In order to avoid too many changes we may space 10-kw. transformers at 1000 ft., changing in three years to 15 kw. or we may put in 15 kw. transformers now at 1500 ft., changing the location in two years to 1000 feet. Other alternatives might be considered but these two will serve as an example.

For the first alternative, assuming uniform increase in load density of 1 2/5 kw. per year.

	Per 1000 ft. installation	
1st year.		
Line Cost — L_D = 8 kw., S = 1000......	$16.00	
Transformer — Cost 10 kw. at 8-kw. load ..	32.00	
For year		$48.00
2nd year.		
Line Cost — L_D = 9 2/5 kw., S = 1000...	16.30	
Transformer Cost — 10 kw. at 9 2/5.......	32.70	
For year		$49.00

3rd year.		
Line Cost — L_D = 10 4/5 kw., S = 1000.	16.80	
Transformer Cost — 10 kw. at 10 4/5	33.70	
For year		\$50.50
4th year.		
Line Cost — L_D = 12 1/5 kw., S = 1000.	17.30	
Transformer Cost — 15 kw. at 12 1/5	42.90	
Cost of Changing Size (10 kw. to 15 kw. on same pole)	7.00	
For year		\$67.20
5th year.		
Line Cost — L_D = 13 3/5 kw., S = 1000.	17.80	
Transformer cost 15 kw. at 13 3/5	43.60	
For year		\$61.40
6th year.		
Line Cost — L_D = 15 kw., S = 1000	18.40	
Transformer cost — 15 kw., at 15	44.40	
For year		\$62.80
Total for 6 years		\$338.90
Second Alternative.		
1st year.		
Line Cost — L_D = 8 kw., S = 1500	17.20	
Transformer Cost — 15 kw. at 12-kw. load.	35.50	
For year		\$52.70
2nd year.		
Line cost L_D = 9 2/5 kw., S = 1000	\$18.00	
Transformer cost 15 kw. at 15 4/5	37.20	
Transformer Cost — 15 kw. at 12-kw. load.	35.50	
For year		\$55.20
3rd year.		
Line Cost L_D = 10 4/5 kw., S = 1000	16.80	
Transformer Cost — 15 kw. at 10 4/5	42.30	
Cost of changing location	20.50	
For year		\$79.60
4th year—same as 1st alternative (less charge for changing size)	60.20	
5th year—same as 1st alternative	61.40	
6th year " " " "	62.80	
Total for 6 years		\$371.90

A saving of \$33.00 per 1000 ft. of installation, or approximately 10 per cent of the total cost over a period of six years by the first method thus demonstrating its economy. It is well to note that a large part of the difference in cost is due to the fact that in the first case the size of transformer is changed while in the other the location but not the size is changed. If a further refinement of the comparison is desired, interest may be considered on the yearly items up to the end of the period under consideration. Usually such refinement is not necessary however.

CONCLUSIONS

A study of all these curves gives considerable aid in determining certain standards of design as well as the final particulars for any special problem. There also may be obtained a definite knowledge of the behavior of secondaries under various conditions of loading and operation. It is purposed here to take up each curve in detail, to bring out its characteristics and its possible use.

Most Economical Voltage Drop. The curves on voltage drop show that the most economical condition varies inversely as the cube root of the wire size also inversely as the cube root of the load density.

For low-load densities the economical drop is high but decreases rapidly, while at high loading the decrease is comparatively slow. It is clearly shown that the most economical voltage drop may be well under that allowable for good service for loads which may be often encountered in practise. Under the conditions and prices assumed in the present case the 3 per cent limit seems to have some justification by economy for ordinary loads.

Two conditions must be considered which might affect these curves, *i. e.*, the price of materials and cost of energy and the fact that here the transformer was considered just sufficient to carry the load while ordinarily, when designing for an increasing load, the transformers are underloaded. It is seen from the equation of the curves for economical voltage drop that the cost of copper does not affect this discussion. This is due to the fact that the annual cost is based on a unit of 1000 feet, hence for any given price of copper the annual cost per 1000 feet of three-wire line is a constant no matter what the load. The cost of energy enters as an inverse factor to the 2/3 power. Also it is a small element in the factor K_1, which is also to the 2/3 power but in the direct ratio. Hence an increase in the cost of energy would increase both the numerator and the denominator but the latter slightly more than the numerator, hence all the curves would be raised slightly. This effect would be small however for ordinary fluctuations. In the case of an increase in the transformer price there would be no change in the curves providing the increase were proportional to the size since the factor K_1 would not be affected by such an increase.

In ordinary design for an increasing load the transformer would be made larger than sufficient to carry the present load to allow for the anticipated increase. A study of the curves for the various components of the annual charge on a transformer and the equation resulting therefrom, Y_T, $= K_1 + K_2 T$, will show that if they are developed with the transformer working below its rated loading, and if the percentage of underloading is kept the same for all sizes, the factor K_1 will be very little affected, the effect being similar to an increase in price proportional to size. Since this is the only part of this equation that enters into the equation for most economical voltage drop it follows that if a design could be limited to any given percentage of underloading throughout, the curves would still show the most economical condition of voltage drop.

Most Economical Transformer Spacing. These curves for the most economical transformer spacing

(curve No. 5) are derived from the same general expression for annual cost per 1000 feet as those for economical voltage drop. Hence the same results might be expected from the use of either of these sets of curves with the exception that where the most economical spacing would give a maximum voltage drop of more than 3 per cent we have corrected it for that value making it such as to give 3 per cent.

These curves show for very low-load densities, extremely high spacings which are probably much greater than it would be practicable to use since for such a distance and such light loads the effect of the non-uniform loading would be considerable. As is shown by the equation, the spacing for 3 per cent drop varies as the square root of the wire size while for greatest economy it varies as the cube root. It also varies inversely with the load density, to the square root in the first case, the 2/3 power in the second. For ordinary loadings encountered in practise and the usual range of wire sizes it is seen that spacing of from 1000 to 2000 feet is the most economical and practicable. For the higher loadings the most economical spacing decreases very slowly, remaining over 500 feet up to high values of L_D.

Changed conditions would have a similar effect on these curves as on those for economical voltage drop, in the range of values for which the most economical voltage drop governs the spacing. That is, a rise in the price of energy would lower the curves slightly; the prices of wire and transformer would not have a noticeable effect. For the condition of underloaded transformers, if the proportion of underloading were fixed there would be slight change. In practical designing, however, when considering the amount of this margin in transformer capacity to be used, it might be found relatively more economical to use a transformer size somewhere near the theoretically most economical and obtain the margin in capacity by using a spacing less than the most economical spacing. This may have some advantage over using the most economical spacing, as shown by the curves, and a larger size of transformer than the most economical, when the design is to cover several years and the cost of changing sizes and locations is taken into account. Hence, care must be used in placing too much dependence on the strictly theoretical values in practical design. The choice must be tested by the actual year costs as shown by the cost curves.

Most Economical Transformer Size. The curves for the most economical transformer size simply show the size of transformer which will carry the load when the spacing is the most economical or just enough to give 3 per cent voltage drop. They have relatively less practical value excepting that it is from these and the spacing curves combined that the practical load curves are obtained.

Most Economical Wire Size. The wire size is the first thing to determine in a design and must be chosen to cover long periods of increase in load as replacement of secondary wire is very costly. Hence for secondaries a standard must be chosen for installation in new work which will show good economy through the greatest range of conditions to be encountered. The curves seem to indicate clearly that under the conditions and prices assumed No. 6 wire should be used as a standard in all new work, in districts where ordinary residence lighting load is expected. The economy curve rises very rapidly at low densities up to about 20,000 cir. mils or nearly to No. 7 at about 7 kw. per 1000 feet. From here the rise is less rapid but still considerable until it crosses the value of No. 6 wire at 15-kw. load density. The load density of 15 is a normal loading. It would not be advisable to use any size less than a No. 7 since the loadings at the smaller values are subject to such rapid increase. Even at No. 7 the economical load is fairly small (7 kw. per 1000 feet). On the other hand, the curve rises slowly after passing No. 6 and only reaches No. 5 at a loading of about 31 kw. and No. 4 at 40 kw. which are high densities and to be encountered only in special cases. It is interesting to note that for all values below a No. 6 wire the economical size is governed by 3 per cent voltage drop while above that the most economical drop governs the curves crossing at 19-kw. load density.

Since the curves were figured at a low copper price, in case of an increase in price, the curves would be lowered, *i. e.*, a smaller wire size would be indicated for any particular loading. An increase in energy cost would slightly raise the curve, an increase in transformer price if proportional to size would not affect the discussion. Since the curves were figured on the assumption that the transformer spacing was the most economical and the size just equal to the load, a change in these conditions might affect the most economical wire size somewhat. A fixed proportion of underloading as above shown would have little effect but if different conditions of spacing were assumed, the design should be tested by use of the cost curves for various sizes of the wire.

Semi-Practical Curves. The curves which we call semi-practical show a little more concretely the relative economy of installations with the various sizes of wire, in dollars per year per 1000 feet. They show the actual annual cost for different types. The excessive cost of No. 2 wire for ordinary loads is clearly demonstrated being from \$3.50 to \$6.00 per year more than No. 4 for loadings up to 15 kw. per 1000 feet.

When we go from the ideal size of transformer to practical stock sizes, still assuming the best spacings to be used, there are some conditions in which the relative wire economy is somewhat different. These curves also give an indication of transformer economy. It seems to be quite clearly shown that, under the assumed conditions, the use of large transformers such as 25-kw. is not justified except with very heavy

loading, even considering the possible reduction in the number of transformers and hence in the core loss. The increase in the investment cost more than equalizes such saving.

Practical Curves. The use of the cost curves in designing has already been explained. It may now be readily seen how a study of the theoretical and semi-practical curves applied to any problem will give a basis upon which to formulate a design which can then be tested for actual economy by application of the exact costs to be expected. We can determine from this, in case of a new line, the size of wire and then the spacing and size of transformers which will care for several years of increase. The exact number of years will be determined by the rate of increase together with the economy of the design, including cost of changing sizes and locations. Or, in case of remodeling an old district, we start with a given size of wire which although perhaps not the most economical, will not justify the cost of change. We can then choose and space our transformers most economically with regard to that size of wire. In a special case where no increase in load is expected the theoretical curves will give exactly the design to use. In other cases where the loading, voltage, etc., are somewhat different, by proper substitution in the theoretical formulas, curves could be plotted which would apply to that particular condition.

General. The curves given here should not be accepted for general application to design problems. The costs and conditions of loading used were of local derivation and apply only to the organization and the time for which they were obtained. Similar curves should be developed for the study of conditions in any other locality and they should be revised from time to time to meet changing conditions. These examples are given here merely to indicate the characteristics of such curves.

It is evident that no very simple means of correctly designing a distribution system in regard to transformers and secondary wire can be made available due to the many varying conditions encountered and the large number of factors to be taken into account.

The elements of good judgment and experience are as necessary in the solution of these problems as in any other problem of engineering. The object of this study has been to analyze and evaluate the factors of the design of the secondary system that lend themselves to such definite analysis and to present the results as aids in the application of good judgment and experience to the best possible solution of the problem.

In conclusion the authors acknowledge gratefully the assistance of Mr. Harold Cole and Mr. Lansing W. Thoms in the preparation of this paper.

APPENDIX A

TABLE OF SYMBOLS

The following is a list of the principal symbols used, with their general definitions. In Appendix B, the significance of each symbol will be explained for the individual case under consideration.

A = cross-sectional area of wire in circular mils.
A_{ec} = most economical cross-section of wire in circular mils.
B = constant relation between per cent voltage drop and per cent power loss.
C_{cu} = cost of insulated copper wire per lb.
C_{e1} = " " core loss per kw-hr. at transformer.
C_{e2} = " " copper loss per kw-hr. at transformer and secondary.
C_{sr} = cost of stringing wire per 1000 ft. of line.
E = Secondary receiver voltage between outside wires.
g = per cent interest, depreciation and taxes (g_t on transformer, g_L on line).
I = total current on secondary.
$K_1, K_2 \cdots K_n$ = the numerical constants.
L_D = load density in kw. per 1000 ft.
R_T = equivalent resistance of transformer in ohms
R = resistance in ohms.
S = spacing of transformers in feet.
S_{ec} = most economical spacing of transformer.
T = size of transformers in kilowatts.
T_{ec} = most economical size of transformer in kilowatts.
t = equivalent hours per day in terms of yearly peak load to give a total energy loss equal to the actual.
V = per cent voltage drop.
V_{ec} = most economical per cent voltage drop.
W = total load on secondary in watts.
w = weight per foot of insulated wire in lb.
Y = total yearly cost per 1000 feet of installation.
Y_T = total yearly cost of transformer per 1000 ft. of installation.
Y_T' = total cost yearly per transformer.
Y_L = total yearly cost of line per 1000 ft. of installation.
Y_L' = total yearly cost of line for given spacing.
Cos θ = power factor of load.
ρ = resistivity of wire in ohms per mil-foot.

APPENDIX B

DERIVATION OF FORMULAS

List of Fundamental Assumptions:

1. Continuous three-wire secondary.
2. Uniformly distributed load.
3. Difference in cost of primary wire and copper loss in primary for different spacing of transformers neglected.
4. Cost of poles, cross arms, pins, insulators and right-of-way same for all cases and hence omitted from discussion.

These four assumptions are carried through the entire study. Any additional assumptions are stated in the derivation of the individual formula.

A. DEVELOPMENT OF THE THEORETICAL CURVES

1. *Annual Cost of Secondary Distribution.*

Annual cost per 1000 feet of installation = Y

Y = (Total annual charges on transformers per 1000 ft. of line) + (total annual charges on line per 1000 ft. of secondary)

$= Y_T + Y_L$ (1)

Where $Y_T = \dfrac{\left(\dfrac{g_T}{100}\text{(purchase price + cost of handling + Cost of installation + cost of lightning arresters and equipment) + cost of core and copper loss + cost of inspection}\right)}{\dfrac{1000}{S}}$

g_T = per cent interest + depreciation + taxes on transformer.

S = spacing of transformers in feet.

Y_T -- can be expressed as a function of the transformer size, T, as follows:

$$Y_T = \frac{1000}{S}(K_1 + K_2 T)$$

Where K_1 and K_2 are constants and are found by plotting total annual charges on transformer against transformer size. (See curve No. 1.)

Assuming a transformer size just sufficient to carry the load, then $T = L_D \dfrac{S}{1000}$.

Where L_D = load density in kw. per 1000 ft.

$$\text{Then } Y_T = \frac{1000}{S}\left(K_1 + K_2 \frac{L_D S}{1000}\right) \qquad (2)$$

Y_L = investment cost of material per 1000 ft. of line + installation charges per 1000 ft. of line $+ \dfrac{1000}{S} \times$ cost of copper loss in secondary.

$$Y_L = \frac{g_L}{100}(3 \times 1000 \times w \times C_{cu} + C_{sr}) + \frac{1000}{S}\left[2\left(\frac{I}{2}\right)^2 \times \frac{\rho}{A} \times \frac{S}{6} \times 2 \times t \times 365 \times \frac{C_{e2}}{1000}\right]$$

Where

g_L = per cent interest + depreciation + taxes on line.

w = weight of insulated wire in lb. per foot.

C_{cu} = cost of insulated wire per lb.

C_{sr} = cost of stringing 1000 ft. of line.

I = total current in secondary at transformer.

ρ = resistivity of wire per mil-foot.

C_{e2} = cost of copper loss in secondary per kw-hr.

t = equivalent hours per day which yearly peak load should continue in order to give an $I^2 R$ loss equal to the total actual $I^2 R$ loss for the year.

A = cross-sectional area of wire in circular mils.

E = voltage between outside wires of secondary.

$\text{Cos } \theta$ = power factor of load.

$$I = \frac{L_D S}{E \text{ Cos } \theta}$$

and

$$Y_L = \frac{g_L}{100}(3000\, w\, C_{cu} + S_{sr}) + S^2\left[\frac{L^2_D}{E^2 \cos^2\theta} \times \frac{\rho}{A} \times t \times 60.83\, C_{e2}\right] \qquad (3)$$

$$\text{Then } Y = \frac{1000}{S}\,\frac{(K_1 + K_2 L_D S)}{1000} + \frac{g_L}{100}(3000\, w\, C_{cu} + C_{sr}) + S^2\,\frac{(60.83\, L_D^2\, \rho\, t\, C_{e2})}{A\, E^2 \text{ Cos } \theta} \qquad (4)$$

Equation (4) gives the total annual cost per 1000 ft. of installation as a function of the spacing and load density.

2. *Most Economical Voltage Drop.*

In order to obtain the most economical per cent voltage drop it is necessary to obtain Y as a function of the per cent voltage drop.

This is done as follows:

W = total load on secondary in watts.

V = voltage drop on secondary in per cent of delivered voltage.

B = constant relation between per cent voltage drop and the per cent power loss.

$$\text{Then } W = L_D S = \frac{A E^2 V}{300\, B\, S}$$

$$\text{Whence } S = \frac{E}{17.32}\sqrt{\frac{A V}{B L_D}}$$

Substituting this value for S in equation 4,

$$\text{Then } Y = \frac{1000\, K_1}{\dfrac{E}{17.32}\sqrt{\dfrac{A V}{B L_D}}} + K_2 L_D + \frac{g_L}{100}(3000\, w\, C_{cu} + C_{sr}) + \frac{E^2}{(17.32)^2}\,\frac{A V}{B L_D}\left[60.83\,\frac{L_D^2\, \rho\, t\, C_{e2}}{A\, E^2 \cos^2\theta}\right]$$

$$= 17{,}320 \frac{K_1}{E} \sqrt{\frac{B L_D}{A}}\, V^{-1/2}$$

$$+ 0.2028 \frac{\rho\, t\, C_{e2}\, L_D}{B \operatorname{Cos}^2 \theta} V + K_2 L_D$$

$$+ \frac{g_L}{100} (3000 \times C_{cu} + C_{sr}) \tag{5}$$

The most economical per cent voltage drop is obtained when the first derivative of Y with respect to V equals 0.

$$\frac{d\,Y}{d\,V} = 0$$

$$= -1/2 \times 17320 \left(K_1 \sqrt{\frac{B L_D}{A}} \right) V_{ec}^{-3/2}$$

$$+ 0.2028 \frac{\rho\, t\, C_{e2}\, L_D}{B \operatorname{Cos}^2 \theta} = 0$$

Solving for V_{ec}

$$V_{ec} = 1223 \left[\frac{\operatorname{Cos}^2 \theta}{E\, \rho\, t\, C_{e2}} \right] \frac{B\, K_1^{2/3}}{A^{1/3}\, L_D^{1/3}} \tag{6}$$

Equation (6) gives the most economical per cent voltage drop as a function of the load density. For fixed values of the constants this equation may be plotted as shown on curve No. 4.

3. *Most Economical Transformer Spacing.*

In order to obtain the most economical spacing of transformers it is necessary to have Y as a function of S. This is obtained from equation (4).

$$Y = \frac{1000\, K_1}{S} + K_2 L_D + \frac{g_L}{100} (3000\, w\, C_{cu} + C_{sr})$$

$$+ S^2 \left(60.83 \frac{L_D^2\, \rho\, t\, C_{e2}}{A\, E^2 \operatorname{Cos}^2 \theta} \right)$$

The most economical spacing is obtained when the first derivative of V with respect to S equals 0.

$$\frac{d\,Y}{d\,S} = 0$$

$$= -\frac{1000\, K_1}{S_{ec}^2} + 2 \times 60.83 \frac{L_D^2\, \rho\, t\, C_{e2}}{A\, E^2 \operatorname{Cos}^2 \theta} S_{ec} = 0$$

Solving for S_{ec}

$$S_{ec} = 2.02 \left[\frac{K_1 E^2 \operatorname{Cos}^2 \theta}{\rho\, t\, C_{e2}} \right]^{1/3} \frac{A^{1/3}}{L_D^{2/3}} \tag{7}$$

Equation (7) gives the most economical spacing of transformers as a function of the load density.

It is necessary to limit the range of application of equation (7) to conditions where the voltage drop is less than 3 per cent. A second equation must be developed for 3 per cent drop to apply where the most economical drop would be greater than 3 per cent. Practical considerations limit the drop to that value.

From above

$$S = E \sqrt{\frac{A\, V}{300\, B\, L_D}}$$

Using $V = 3$ per cent

$$S = \frac{E}{10} \sqrt{\frac{A}{B L_D}} \tag{8}$$

= transformer spacing for 3 per cent drop.

Then, summarizing,

$$S_{ec} = 2.02 \left[\frac{K_1 E^2 \operatorname{Cos}^2 \theta}{\rho\, t\, C_{e2}} \right]^{\frac{1}{3}} \frac{A^{\frac{1}{3}}}{L_D^{\frac{2}{3}}}$$

$$< \frac{E}{10} \sqrt{\frac{A}{B L_D}} \tag{7a}$$

which is general for all cases. (See curve No. 5.)

4. *Most Economical Transformer Size.*

The most economical size of transformer will follow directly from equation (7a) since it would be that size which would just carry the load at the most economical spacing.

or,

$$T_{ec} = \frac{L_D\, S_{ec}}{1000} \tag{9}$$

(See curve No. 6.)

5. *Most Economical Wire Size.*

The most economical cross-section of wire is the cross-section which will give the minimum total annual cost with any particular type of transformer installation. Here, the condition of most economical spacing and size of transformers will be assumed.

Thus, substituting the value S_{ec} (equation 7) for S in equation 4,

$$Y = \frac{1000\, K_1}{2.02 \left(\frac{K_1 E^2 \operatorname{Cos}^2 \theta}{\rho\, t\, C_{e2}} \right)^{\frac{1}{3}} \frac{A^{\frac{1}{3}}}{L_D^{\frac{2}{3}}}}$$

$$+ K_2 L_D + \frac{g_L}{100} (3000\, w\, C_{cu} + C_{sr})$$

$$+ 60.83 \frac{L_D^2\, {}_m\, t\, C_{e2}}{A\, E^2 \operatorname{Cos}\theta^2} \left[2.02^2 \left(\frac{K_1 E^2 \operatorname{Cos}^2 \theta}{\rho\, t\, C_{e2}} \right)^{\frac{2}{3}} \frac{A^{2/3}}{L_D^{4/3}} \right]$$

It is possible to express w as a function of A as follows:

$$w = \frac{K_3 + K_4 A}{100}$$

Where K_3 and K_4 are found by plotting the weight of installed wire against its cross-sectional area. (See curve No. 2.)

The equation for annual costs per 1000 ft. now becomes

$$Y = \frac{496\, (K_1^2\, \rho\, t\, C_{e2})^{1/3}\, L_D^{2/3}}{(E^2 \operatorname{Cos}^2 \theta)^{1/3}} A^{-1/3} + K_2 L_D$$

$$+ \frac{g_L}{100} [30\, (K_3 + K_4 A)\, C_{cu} + C_{sr}]$$

$$+ 248.5 \frac{(K_1^2 \rho t C_{e2})^{1/3}}{(E^2 \operatorname{Cos}^2 \theta)^{1/3}} L_D^{1/3} A^{-1/3}$$

Simplifying

$$Y = 744.5 \left(\frac{K_1^2 \rho t C_{e2}}{(E^2 \operatorname{Cos}^2 \theta)} \right)^{\frac{1}{3}} L_D^{1/3} A^{-1/3} + K_2 L_D$$

$$+ \frac{g_L}{100} [30 (K_3 + K_4 A) C_{cu} + C_{sr}] \quad \textbf{(10)}$$

Equation (**10**) gives the annual cost per 1000 ft. of line, using the most economical spacing of transformers.

The most economical cross-section of wire is obtained when the first derivative of Y with respect to A equals 0 or

$$\frac{d Y}{d A} = 0$$

$$= - 1/3 \times 744.5 \left[\frac{K_1^2 \rho t C_{e2}}{E^2 \operatorname{Cos}^2 \theta} \right]^{\frac{1}{3}}$$

$$L_D^{1/3} A_{ec}^{-4/3} + \frac{g_L}{100} \times 30 K_4 C_{cu}$$

Solving for A_{ec}

$$A_{ec} = \frac{154}{g_L K_4 C_{cu}^{3/4}} \left[\frac{K_1^2 \rho t C_{e2}}{E^2 \operatorname{Cos}^2 \theta} \right]^{\frac{1}{4}} L_D^{1/4} \quad \textbf{(11)}$$

Equation (**11**) gives the most economical cross-section of wire using the most economical spacing of transformers.

It is necessary to limit the application of equation (**11**) to less than 3 per cent voltage drop and develop the equation for most economical wire size *with* 3 per cent drop. This is done as follows:

From the equation (**8**), the spacing which will give a 3 per cent voltage drop is,

$$S = \frac{E}{10} \sqrt{\frac{A}{B L_D}}$$

B may be expressed as a function of A as follows,

$$B = K_5 + K_6 A$$

Where K_5 and K_6 are found by plotting B against the cross-sectional area, (see curve No. 3). Then:

$$S = \frac{E}{10} \sqrt{\frac{A}{(K_5 + K_6 A) L_D}}$$

Substituting the value of S in equation (**4**), the expression for annual costs per 1000 ft. of line—(the spacing being limited for a 3 per cent voltage drop) becomes

$$Y_{3\%} = \frac{1000 K_1}{\frac{E}{10} \sqrt{\frac{A}{(K_5 + K_6 A) L_D}}} + K_2 L_D$$

$$+ \frac{g_L}{100} [30 (K_3 + K_4 A) C_{cu} + C_{sr}]$$

$$+ 60.83 \frac{L_D^2 \rho t C_{e2}}{A E^2 \operatorname{Cos}^2 \theta}$$

$$\times \frac{E^2}{100} \frac{A}{(K_5 + K_6 A) L_D}$$

Simplifying

$$Y_{3\%} = \frac{10{,}000 K_1 L_D^{1/2}}{E} \left(\frac{K_5}{A} + K_6 \right)^{\frac{1}{2}}$$

$$+ K_2 L_D + \frac{g_L}{100} [30 (K_3 + K_4 A) C_{cu}$$

$$+ C_{sr}] + 0.6083 \frac{\rho t C_{e2} L_D}{\operatorname{Cos}^2 \theta (K_5 + K_6 A)} \quad \textbf{(12)}$$

Equation (**12**) gives annual cost per 1000 ft. of line using a spacing which limits the voltage drop to 3 per cent at full load.

The most economical cross-sectional area is obtained when the first derivative of $Y_{3\%}$ with respect to A is equal to 0.

$$\frac{d Y_{3\%}}{D A} = 0$$

$$= 1/2 \frac{10{,}000 K_1 L_D^{1/2}}{E} \left(\frac{K_5}{A_{ec}} + K_6 \right)^{-\frac{1}{2}}$$

$$\left(- \frac{K_5}{A^2_{ec}} \right) + \frac{g_L}{100} \times 30 K_4 C_{cu}$$

$$- 0.6083 \frac{\rho t C_{e2} L_D}{\operatorname{Cos}^2 \theta (K_5 + K_6 A_{ec})^2} K_5$$

From which

$$\frac{5000 K_1 K_5 L_D^{1/2}}{E \left(\frac{K_5}{A_{ec}} + K_6 \right)^{\frac{1}{2}} A^2_{ec}}$$

$$+ 0.6083 \frac{K_6 \rho t C_{e2} L_D}{\operatorname{Cos}^2 \theta (K_5 + K_6 A_{ec})^2}$$

$$= 0.30 g_L K_4 C_{cu} \quad \textbf{(13)}$$

Equation (**13**) gives the most economical cross-sectional area of wire when the spacing is limited by a 3 per cent voltage drop. (See curve No. 7.)

B. Derivation of the Practical Curves

1. *Load Curves for Secondaries.*

From equation (**7a**)

$$S_{ec} = 2.02 \left(\frac{K_1 E^2 \operatorname{Cos}^2 \theta}{\rho t C_{e2}} \right)^{\frac{1}{3}} \frac{A^{1/3}}{L_D^{1/3}}$$

$$< \frac{E}{10} \sqrt{\frac{A}{B L_D}}$$

From the combination of these two formulas the load curves for secondaries were obtained.

The lines showing the various load densities are obtained as follows:

$$\text{Total load in kw.} = \frac{L_D}{1000} \times S_{ec} \qquad (17)$$

(See curve No. 10.)

2. *Line Cost Curves.*

From equation 3,

$$Y_L = \frac{g_L}{100}\,(3000\, w\, C_{cu} + C_{sr}) + 60.83\, \frac{L_D{}^2\, S^2\, \rho\, t\, C_{e2}}{A\, E^2 \operatorname{Cos}^2 \theta}$$

The line cost curves are obtained by substituting the actual values of the various constants into this equation. (See curve No. 11.)

3. *Transformer Cost Curves.*

Annual cost of the transformer =

$T_{T1} = g_T$ (Cost of transformer + cost of light . arrest . + cost of installation) + inspection
+ cost of core loss
+ cost of copper loss

$= \frac{g_T}{100}$ (Cost of transformer + cost of lightning arresters + cost of installation)
+ cost of inspection

$$+\, C_{e1} \times 365 \times 24 \times \frac{\text{core loss}}{1000}$$

$$+\, \frac{L_D{}^2\, S^2}{E^2 \operatorname{Cos}^2 \theta}\, R_T \times 365 \times t \times \frac{C_{e2}}{1000} \qquad (18)$$

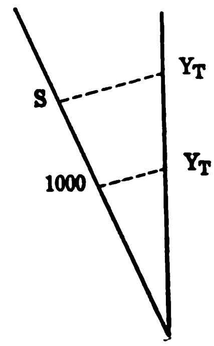
The method for determining Y_T (the cost per 1000 ft. of installation) graphically from Y_T (the total cost on one transformer) is as follows,

$$\frac{S}{1000} = \frac{Y_{T'}}{Y_T}$$

$$\therefore\; Y_T = Y_{T'} \times \frac{1000}{S}$$

($Y_{T'}$ = total annual cost on a transformer)
Y_T = annual cost of transformers per 1000 ft. of installation)
(See curve No. 12.)

Hence by adding the diagonal scale at the left, Y_T may be obtained from $Y_{T'}$, as follows by the method of similar triangles. Draw a line from the value of $Y_{T'}$, obtained on the vertical scale to the value of S used, on the diagonal scale. Draw a parallel line through 1000 ft. on the diagonal scale and where it intersects the vertical scale will be found the desired value of Y_T.



CORRESPONDENCE

THE ICE PROBLEM

To the Editor:

On page 786 of the JOURNAL for August 1920, there is an article entitled "An American Hydraulic Laboratory," which is of unusual interest to me.

For many years, almost single-handedly, I have been demonstrating the fact that submerged hydraulic apparatus—insulated or protected from the cooling action of the winter atmosphere—can easily be made immune from frazil, or anchor ice, attacks. The small amount of energy, in the form of heat, which is needed to secure such immunity makes the undertaking attractive to those who are impressed with the necessity of uninterrupted service from hydraulic plants.

During the past couple of years, I have, I think, taken a long step forward and have been showing with the aid of "moving" and other pictures that ice, itself, can be easily and economically *prevented from forming* in a stream or lake.

It appears to me that Ice-Prevention is on a par with Fire-Prevention, and that the very small amount of heat required to prevent ice from forming is quite comparable with the small amount of moisture which will often *prevent* inflammable materials from catching fire. Immense quantities of water are needed to stem the onrush of a conflagration—or to confine it to the limits of its starting point—but a few drops of water might in the beginning have quenched the spark which started the conflagration.

Crystallization is stayed or delayed in water at the critical temperature until an ice-forming nucleus is introduced, or until one is created by agitation; then crystallization proceeds with great rapidity—each new particle of ice becoming, in turn, the nucleus for the creation of myriads of others. The sequences of procedure in ice-formation resemble, greatly, the cumulative activity of a conflagration.

And so, also, it seems to be with ice. A "little" heat —(like the "little" moisture for fire-prevention)—applied to the molecule of water about to crystallize *prevents* its crystallization and stays the starting of the "conflagration" of ice.

The above points have already been presented to a number of technical gatherings and will, it is hoped, be again submitted, with illustrations, to some Sections of the Institute during the approaching meetings season. But it would give me much pleasure to present the material which I have gathered during many years to some "competent experimenters" in a "Hydraulic Laboratory" if the latter were equipped with the means of further widening the trail which I have been blazing.

These hydraulic and ice problems are, in my opinion, of nation-wide interest.

The Measurement of Maximum Demand

AND

The Determination of Load Factor

BY PERRY A. BORDEN

Hydroelectric Power Commission of Ontario.

SINCE Hopkinson in 1892 first suggested the idea that the distribution of a customer's load throughout the day should have some bearing upon the amount which that customer should pay to the Central Station for his power, the subject of demand and load-factor measurement in its various aspects has been many times discussed. In the determinination of watts, amperes or any similar electrical quantity we have definite units upon which to base our measurements, and there is little room for controversy. But, when the quantity "demand", being a more or less mathematical concept, embodying the combination of electrical units with time in a rather indefinite way, comes under consideration, very divergent views as to its nature, measurement and true significance may be and have been expressed.

The object of the present paper is not to introduce any radically new ideas, nor is it to advocate any particular policy as a panacea for all difficulties which beset the rate maker in his work. It is rather to give a bird's-eye view of the situation as it exists today; and, in an endeavor to reconcile some of the different opinions on the subject to show an actual comparison of the performances of a number of demand-measuring devices. And from this comparison have been deduced some interesting facts which would seem to have an important bearing upon the present day status of industrial load measurement.

For the purpose of a systematic study of the measurement of electrical demands the subject may be divided into three natural sections as follows:

I. The electrical quantity upon which the measurement is performed.

II. The method by which the measurement is accomplished.

III. The results obtained by the several methods upon a variety of types of loads.

Although these aspects of the subject are closely related, they will be considered as independently as possible, one of another.

I. The Quantity Measured

In the establishment of a scale of charges for electrical energy the rate-maker at once recognizes the fact that he has the choice of a number of electrical quantities upon which to base his calculations. These quantities are affected in various ways by the nature and magnitude of the load under consideration. If the value received by a consumer from a certain amount of electricity were in direct proportion to the expense incurred in placing that electricity at his disposal, the problem of establishing charges for electrical power would be immensely simplified. Unfortunately, however, such is not the case; and the problem becomes one of finding a middle way between an absolute flat rate, based only upon the installed capacity of the load, and a straight energy charge established upon the readings of a watt-hour meter.

In hydroelectric power plants, where the fuel costs are nil, and the apparatus may be run at its ultimate capacity at practically no more outlay than at very light loads, the limitation of output is the *capacity of the equipment.* In fuel-consuming plants, where the combustion of coal or of oil is the source of energy, the cost of fuel, (the only item of cost whose value bears any direct ratio to the energy output), is seldom over half the annual expense of the undertaking, the remaining charges being practically dependent upon the capacity of the plant. In either case, therefore, the relationship between the watt-hours supplied and the cost of operation is a very indefinite one. The main object to be attained is that of keeping up the load factor; and the logical way to produce this result is to encourage each customer to do his share. It has of course, been demonstrated that cases may exist where it is desirable to have on the system a customer with a low load factor, who, by placing his peaks at the discretion of the Central Station, may serve to fill up the valleys in the load curve caused by another customer who cannot so well control his demands; but practically all such cases are of a particular nature; and as such, need not be considered under the general head. The most natural way to encourage a high load factor is by the production of a direct reaction upon the customer's pocketbook, and hence the justification of the use of demand in the establishment of rates.

The "capacity of the equipment" referred to in the former paragraph is a term which in itself might furnish material for much discussion, and its very uncertainty adds much to the intricacies of the problem of demand measurement. To the mechanical engineer such a term would present little difficulty, as it would merely signify a power value beyond which the weakest link in the system would fail. But to the electrical engineer the matter of heating of equipment is usually fully as important as any purely mechanical feature; and this heating is not in direct propor-

To be presented at a meeting of the A. I. E. E., Philadelphia, October 8, 1920.

tion to the amount of energy delivered to the consumers.

The temperature rise of a piece of apparatus is governed by the relation of the energy losses therein to the facilities for dissipating the heat generated, and to the time allowed for the heat to distribute itself away from its source. All of these factors are subject to great variation. If then, we wish to base our charge upon the capacity of the plant or investment necessary to provide power for the customer in question, we must pay some consideration to the temperature rise of our equipment due to his load. This means that, to obtain a fair basis we should endeavor to determine the energy loss produced in our equipment by the load under consideration and to incorporate this value in his power bills.

The direct measurement of loss, while possible on a single unit by use of a differential wattmeter, or by other means, is not practicable where the one bus supplies a number of independent loads. It is desirable, therefore to install upon each circuit that type of measuring instrument whose indications bear the closest relationship to the enrgy losses in the supply system. Hence the question, "What electrical quantity shall we measure?"

As possible answers to this question, consideration is given to the follwing quantities:

(a) Watts ($E\ I$ Cos ϕ)

The majority of the present day demand meters operate as wattmeters and give the maximum demand of the load in watts consumed. This method has the advantage that it is universally applicable to all classes of loads,—direct and alternating, single-phase and polyphase, balanced and unbalanced. This value while representing the demands made upon the mechanical portions of the system, is not of necessity proportional to the heating effects.

(b) Volt-Amperes ($E\ I$)

Since for a given energy load, the heating of equipment is manifestly greater at low power factors than at high, a consideration of volt-amperes without regard to the actual energy supplied will have a tendency to encourage operation at high power factor, and thus reduce energy losses. This method is already used to a considerable extent by the employment of a watt-demand meter whose readings are coupled with those of a power factor meter at the time of the maximum demand. This scheme, however, or the use of a reactive-volt-ampere-meter in conjunction with a watt-demand meter involves the use of two instruments, one at least, of the curve-drawing variety; and is, therefor, suitable only for comparatively large loads from which the revenue would be sufficient to justify the expense of the equipment.

The volt-ampere meter has not yet been developed in a form suitable for direct determination of maximum demand, and does not at this time appear capable of such development, at a price to compete with the watt-demand meter on ordinary commercial measurements.

(c) Amperes (I)

The earliest types of demand indicators were dependent for their indications upon current alone. And, since it is the current which is responsible for the heating of conductors, there would seem to be justification for their use. On polyphase circuits, however, they are likely to introduce confusion and uncertainty.

(d) Amperes Squared (I^2)

As the heating of a conductor is directly proportional to the square of the current flowing, it would seem that an instrument measuring demand upon this basis would find a certain sphere of usefulness. Such a meter would be identical in its principles with an ampere-demand meter, but would have an inherently uniform scale. Its construction, to operate upon either a thermal or an electro-mechanical principle should be quite practicable. It would, however, on unbalanced loads, be subject to the same limitations as the ampere-demand meter.

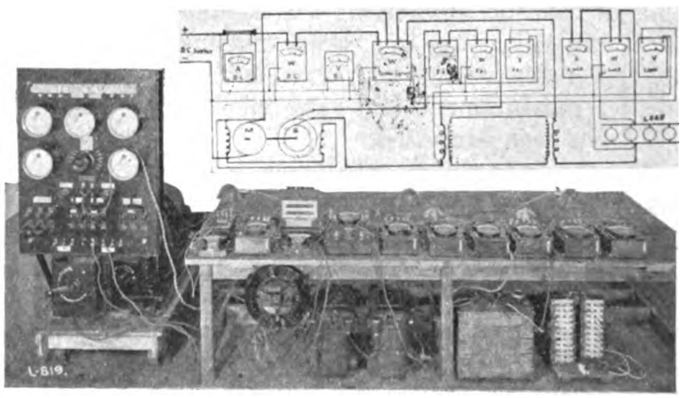

FIG. 1—TEST ON TRANSMISSION LOSSES

(e) Actual Energy Losses ($K\ E^m + R\ I^n$)

As stated above, while it is possible to measure the actual energy losses in a simple system, where but one load is fed from the portion of the plant under consideration; it is not practicable, when several loads are fed from one source, to apportion the responsibility for the energy losses without the most intricate mathematical operations and complicated metering equipment. The accurate measurement of energy losses under ordinary working conditions may be looked upon as a matter of purely academic interest and here laid aside in favor of some more practical if less precise method.

As a matter of interest, a number of tests were made upon a load fed through a series of circuits forming an artificial transmission system. The arrangement, as shown in Fig. 1, consisted of a direct-current motor driving a small alternator whose output was stepped up to the line, and down again to the load. Complete measuring equipment was installed at several points along the system, and a differential wattmeter connected in so as to totalize the losses. One set of curves was made with non-inductive load-

ing, and another considerable reactance in the circuit to produce a low power factor.

The values obtained in these tests are shown in Figs. 2 and 3 where the various quantities are expressed as curves on a base of watts input to the system. The curve of total loss in the system manifestly represents only the difference between the total input and the total output, and the same, of course, holds good for any portion of the system which it

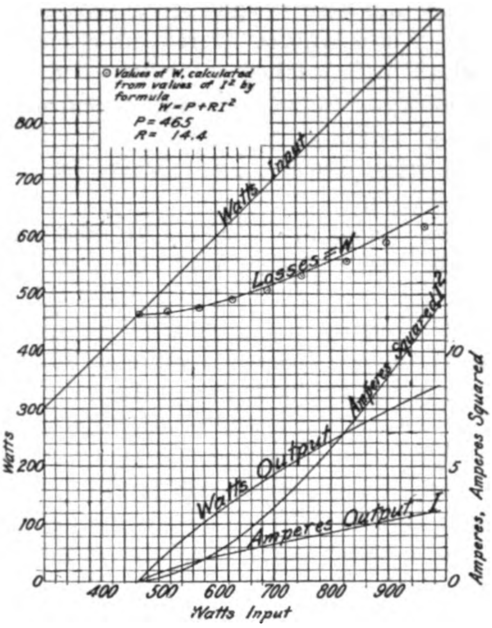

Fig. 2—Loss Measurements on Unity Power-Factor Load

is desired to investigate. The total losses of the system, including those of the motor-generator set, the transformers and the line, are in this case taken, as being representative of the greatest variety and magnitude of energy losses, and therefore approaching most closely the average power system.

A glance at the curve sheets suffices to show that, whereas the watt and volt-ampere curves bear but little resemblance to that of the energy loss; a strong similarity exists between the loss curve and the curve of amperes squared. It is a simple matter to develop an expression connecting the two quantities, which, from the values of amperes squared will enable us to construct the curve of losses.[1] This, while quite applicable to those portions of the system which supply only one customer, is subject to the same handicap as other methods of total energy loss determination, where several consumers are fed from the one bus.

Summary—Part I.

1. A fair and equitable charge for electrical energy cannot be made on a basis of energy consumption alone. Some consideration must be made of the customers' demand upon the capacity of the plant.

2. In the determination of demand, cognizance should be taken of the heat produced in the equipment by the load under consideration, as well as of the mechanical limitations of the plant.

3. While the mechanical limitations of the plant bear a direct relationship to the energy output, the heating limitations are in direct proportion to the energy losses in the electrical equipment.

4. Energy losses cannot generally be measured, and are usually very difficult to estimate accurately.

5. Energy loss may be expressed as the sum of a function of the voltage and a function of the current; and considering the complicated nature of the expression necessary to give a precise representation of this value, the voltage may usually be considered as constant, and the loss said, with little sacrifice of accuracy, to vary as the square of the current,

6. An exact apportionment of the I^2R losses among several loads fed from one system is made difficult by the fact that, while the total loss varies as the square of the total current, the ratio of the losses due to the respective currents is an indefinite quantity, depending upon a number of variables whose values it is not practicable to obtain.

7. Since the true basis for demand measurement is an exceedingly evasive quantity, not capable of determination under practical working conditions, it is necessary that some compromise be made, and

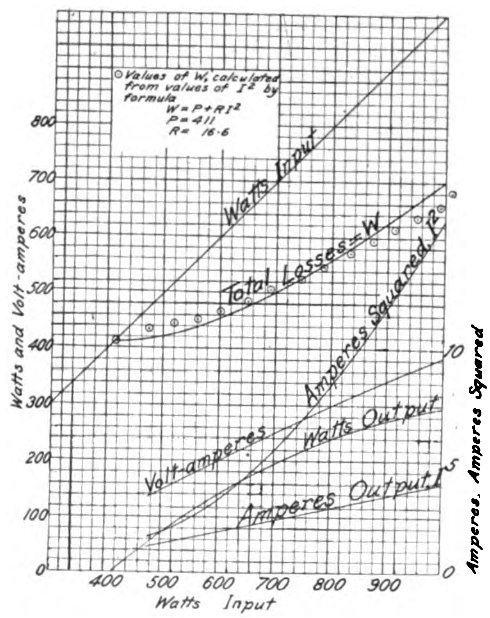

Fig. 3—Loss Measurements on Low Power-Factor Load

the nature of this compromise must be subject to local conditions and to personal opinions on the economic questions concerned.

8. Tests would seem to indicate that, though volt-amperes cannot be said to be an exact representation of the quantity upon which demand would be based, they furnish us with a definite quantity whose value approaches nearest to the desired approximation.

1. See Appendix No. 1.

II. The Method of Measurement

In the present state of the art, there are recognized several methods of determining demand: These include measurements from the charts of graphic recording instruments, and readings obtained from specially designed demand meters. While from an analysis of the graphic meter chart it should be theoretically possible to determine the average power for any period and to select the greatest of these averages as the maximum demand, any person who has tried to do this with the chart of a load having any considerable degree of variation realizes that a positive determination of the true average over a chosen period is seldom practicable.

The only workable method of measuring maximum demand from graphic meter charts is by selecting that portion of the curve during which the indication remains at its highest value for the duration of the required time period. This is known as the "Sustained Peak." While the use of this quantity, in that it cannot exceed the true maximum integrated demand, might well meet with the customers' approval, it may be very unfair to the Central Station, in that the value obtained cannot be higher than the minimum point of any depression which may occur during the period of maximum demand. Moreover, the depth of any instantaneous minima of the load curve as drawn by the graphic instrument will depend greatly upon the amount by which the meter movement is damped. In Fig. 4 is shown a reproduction of charts taken simultaneously on the one load, by curve-drawing meters of different types. One of these instruments was of the well-known relay type; while the other, operating upon the induction principle, had almost critical damping. From these charts it will be seen that, by a slight difference in the operating characteristics of the recording meters, the load is shown, not only as having sustained peaks of differing values,

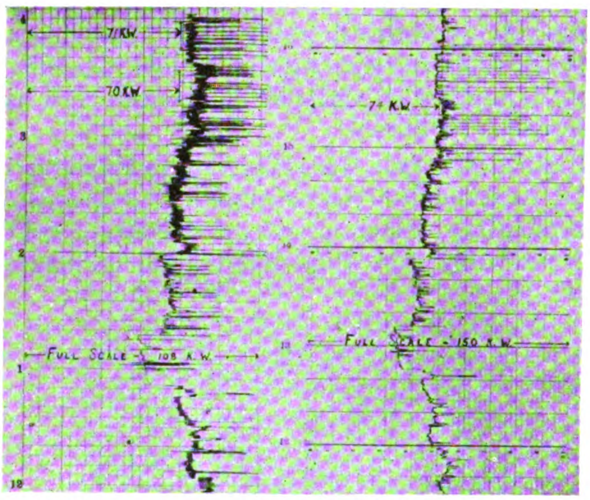

Fig. 4—Simultaneous Charts From Different Types of Curve-Drawing Meters Showing Sustained Peaks

but as having its peaks at different times of the day. Thus, on a fluctuating load, the values of maximum demand, as determined from the sustained peak are of little significance.

Since the ordinary curve-drawing meter does not justify its use for the determination of demand, it becomes necessary to investigate the possibilities of the various types of demand meters which, from time to time, have been developed; and to examine their principles of operation.

Among the numerous types of demand instruments now known to engineers there are recognized two groups, which are classified according to the principle of operation rather than the quantity measured. These classes are as follows:

1. Those from which an integrated value of the load is obtained.
2. Devices which are time-lagged and cannot, in the ordinary sense of the word, be said to give an integrated value.

Integrated Demand Instruments. The quantity determined by this class is usually the ratio of the total integrated value of the load consumed in the time interval to the time of the interval. This class naturally falls into five subdivisions of which, as we proceed, I shall endeavor to briefly describe one or more types to be found in each.

(a) Curve-drawing meters include all meters which give a continuous line record or chart of the quantity measured. From the charts so obtained it is possible by measurement or by integration to gain very complete information as to the load, its peaks, its total value and its demand over any desired period. But as shown in a previous paragraph, the systematic use of such instruments for the accurate measurement of demand is seldom practicable.

(b) Instruments which graphically record the demand for each successive time interval as fixed by a clock or other timing device, time also being recorded. The demand in each clock interval, and therefore the maximum demand, can be obtained from the record. This type and those in the two following classes operate upon what is known as the "Merz" principle, and are subject to the disadvantage that, the time periods being selected by a clock, no cognizance is taken of load conditions immediately previous or subsequent to each individual demand. The clock being unable to select the period of maximum power, the maximum demand as obtained from such an instrument is only the greatest of those demands which were measured by the individual meter in question. Two similar meters installed upon the same load, unless the tripping mechanisms operate in synchronism, need not indicate the same value. As examples of meters in this class may be named the General Electric type *G* meter, the Westinghouse type *R A* and the Piek or the N. E. I. C. meter.

The General Electric type *G* meter has essentially

two parts, a registering element and a timing element, both of which are mounted within the same case. In addition to the device proper, a complete outfit includes a contact device consisting of cam and contact brushes for mounting in the register of the watt-hour meter with which the demand meter is to be used. The registering element consists of a marking stylus, the electromagnet, ratchet and pawl mechanism, and gearing to transmit motion from the armature of the electromagnet to the stylus. The timing element consists of an eight day clock which drives the chart, and, at the end of each time interval, resets the stylus to its zero position. The charts are circular and arranged to cover a period of one week. They are made of a special coated paper similar to that used for steam engine indicator cards; and the record is made by a steel stylus.

The Westinghouse type *R. A.* meter combines the demand mechanism and the integrating mechanism in one case and the connection between the two is mechanical. The record paper is in the form of a strip and is of sufficient length to last for thirty-six days. The chart does not travel continuously but is advanced a short distance just before the pen is released and reset. Thus each demand indication is given a square top that makes it distinctly readable.

The Piek demand meter is probably the first graphic demand meter to make its appearance in this country. It was introduced about 1910. The measurement of energy is accomplished by a Westinghouse type *C* watt-hour meter bearing the ordinary integrating dial. Geared to, and operated by the meter is a parallel motion carrying a pen or stylus which travels in a straight line across the scale. The position of the pen is at all times recorded upon a paper chart driven forward by a self-winding clock. This clock serves also to drive a cam which, operating an electric tripping device, periodically releases the pen, and resets the demand mechanism to zero. These meters are built for periods ranging from one minute upwards.

(c) Instruments which, at the expiration of each time period, make upon a tape or chart; a record of the reading or of the advance of an integrating meter. These meters are very similar to the foregoing class, except that whereas in the former, the record is graphic, in this case it is in figures. The "Printometer," now known as the General Electric type *P* demand meter is the best known example. The instrument contains a set of cyclometer type-wheels which are electrically interlocked with the register of a watt-hour meter. They are moved forward at a rate representative of the flow of power through the meter; and will, therefore, at any instant give an indication which is equivalent to the reading of the dial. Through the agency of a rubber platen and a copying ribbon, this reading is printed on a paper tape. The outfit is not self-contained, the demand indicator being separate from the clock and the meter, and requiring, like the type *G*, a contact-making device to be fitted to the register of the meter.

(d) Instruments which indicate, but do not record the maximum demand, the time intervals being fixed by a clock or other timing device. In meters of this class, the reading is obtained from a pointer, which must be manually reset to zero, and which gives only the maximum demand since the last previous resetting. As examples of this class may be named the General Electric type *M* (formerly the Maxicator) and the Siemens demand meter.

In its general principles the type *M* is similar to the type *G*. As the stylus is replaced by a pointer, however, it is not automatically returned to zero. The mechanism which forces the pointer across the scale returns periodically to zero but the pointer remains at a maximum deflection, and is reset by hand when the meter reading is taken. Instead of a clock, the *M* 4, for alternating currents, has for a timing element a constant-speed motor similar in its construction and operation to the moving element of an ordinary watt-hour meter.

The Siemens meter consists of a demand attachment mounted in the same case with a watt-hour meter of the standard type. The clock is a small, electrically-driven unit which, by means of a cam, mechanically actuates the tripping mechanism. A driving dog periodically geared to the watt-hour mechanism, impels a pointer around a graduated scale, and the position of the pointer indicates the maximum deflection of the dog, and hence, the maximum demand, since the pointer was last reset. At the time of reading the meter, this pointer is manually reset to zero. The Siemens meter, being of the purely indicating type, requires no attention other than the periodic reading and setting of the demand pointer.

A considerable number of meters using the Merz principle have been developed by British and European manufacturers but these differ from the Siemens meter only in details of construction.

(e) Instruments which make a record on a tape or chart when a certain fixed and predetermined amount of energy has been consumed, time also being recorded. This class differs from class (c) in that the demand is shown for any time interval, irrespective of when the interval began and ended. In other words, when a predetermined amount of energy has been consumed, a record is made, while in class (c) instruments a record is made when the predetermined time interval has elapsed. It differs from class (a) in that the record is not a continuous one but periodic. Example: Ingalls demand recorder. In this meter the general scheme of operation is similar to that of the General Electric type *P* but the functions of the timing and recording elements are interchanged. A dot is made on the paper tape after the consumption of each predetermined block of energy. The rate of consumption is obviously greatest where the dots are most numerous.

Numerous attempts have been made to develop a meter which would overcome the selective characteristic of instruments of the Merz type; but owing to their mechanical complications, these cannot be said to have found sufficient favor to justify their production in quantities. A special instrument developed for this purpose by the writer is described in a later section of this paper.

Lagged Demand Instruments. A lagged demand instrument really comprises an indicating meter in which a retarding device is used, so that a definite time period must elapse before the full value is indicated. The time interval is independent of clock time.

The value measured by instruments in this general class differs from the integrated value by an amount which depends upon the particular type of instrument and the character of the load curve. With a perfectly steady load, all instruments of this class would indicate practically the same value as integrating instruments, but with a fluctuating load each type may give a different result. Hence, when referring to demands measured with instruments of this class, the particular type of meters employed should be mentioned. The class may be subdivided into the following two types:

(a) Instruments in which the rate of motion of the indicator over the scale is always proportional to the load. Example: Westinghouse type *R. O.* meter.

The Westinghouse type *R. O.* watt-hour demand meter, which made its appearance six years ago, embodies some distinctly original features. It combines in the one mechanism a wattmeter and watt-hour meter, both actuated by the same electromagnetic elements. The wattmeter is prevented from registering the instantaneous value of the load by an escapement operated from the watt-hour meter shaft. The indicating mechanism, therefore, constantly endeavors to indicate the load; but can only approach that value (as long as the indication is less than the load) at a rate proportional to the load. Since the speed of travel is proportional to the load, it will be seen that an indication of any sustained load will be attained at the end of a definite and constant time interval. The time period is thus established independently of any clock. Engaged with the indicating mechanism is a maximum pointer, which, by indicating the greatest deflection of the wattmeter element, determines the maximum demand.

Several instruments measuring substantially the same quantities as the *R. O.* meter have recently been patented, but as they have not made their appearance on the market it is not necessary to refer to them here.

(b) Instruments in which the rate of motion of the indicator decreases with the time of deflection. Examples: Wright, Reason, Lincoln type *R. H.*, General Electric types *W* and *H*.

The Wright meter is in principle a differential recording thermometer which measures the heat produced by an electric current. It consists of two bulbs of approximately the same size, connected by a U-tube filled with liquid and provided with a third tube; in close proximity to which the scale is fixed. The current is carried through a heating coil wound on one of the bulbs. The heat produced causes the air to expand and to depress the column of liquid in one side of the U-tube, causing it to rise in the other and overflow into the reading tube. The height to which it finally rises is an indication of the maximum value of the current which has passed through the coil.

The Reason demand meter is a similar piece of apparatus in which the glass tube is tilted by the measured current flowing in a solenoid, thus allowing the liquid to flow into the reading tube. Both this and the preceding type, being unaffected by the voltage of the circuit are purely ampere-demand meters.

The Lincoln type *R. H.* meter having already been described both in theory and in mechanical construction to the A. I. E. E.,[2] it is assumed that a very brief description will suffice to recall to mind its operating principles.

This demand indicator operates upon the principle of heat storage. By an ingenious, though simple arrangement of transformers and resistors it has been practicable to obtain a thermal quantity which is directly proportional to the energy in the circuit. An expanding spring, connected to a deflecting pointer enables an indication to be obtained of the watts passing through the metering element, and the instrument constitutes a true thermal wattmeter. The time element is introduced by loading the heaters with metallic masses, which do not instantly respond to temperature changes. Upon any change in load, the temperature of the mass begins to change and continues to do so until the rate of heat loss balances the rate at which energy is being supplied. This change in temperature takes place according to what is known as a logarithmic law.

The General Electric type W demand meter is essentially a polyphase watt-hour meter with both electrical elements acting upon one disk, and a very strong damping system acting on the other disk to produce the necessary time lag. The rotating element is opposed by a series of springs which permit the disks to make three complete revolutions while the pointer makes one revolution. The instrument thus becomes an indicating wattmeter, very much over damped. This meter is usually constructed to have a time period of five minutes.

The type *H* is a thermal instrument and records the maximum current. The instrument works on a differential thermometer principle. Two similar thermostatic springs are mounted on studs, their free ends being connected by a cord which passes over

---

[2] Trans. A. I. E. E. Vol. XXXIV, p. 2297

a spindle, the latter carrying an arm which engages the pointer. The air temperature affects both springs to the same extent, thus causing no deflection of the pointer for its variations. In one of the two spring-supporting studs is contained a heating element through which the main current is passed; thus when current is being used, the temperature of one spring is raised above that of the other, causing the shaft to turn, and so produce a reading. This instrument combines in its principles the idea of the logarithmic increment of temperature, with that of the flow of heat along conductors.

The demand meters referred to above include only types which are now, or have been in actual commercial use. It is not the intention to convey the impression that these are all the types that have ever been de-

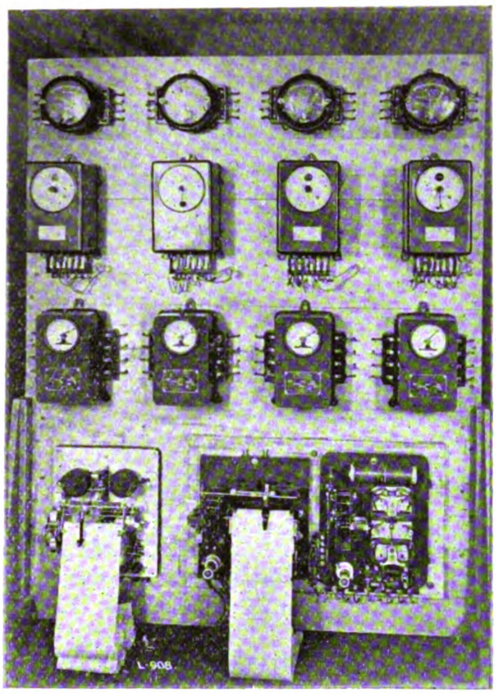

Fig. 5—Comparative Demand Meter Outfit

veloped. To obtain an adequate idea of the multitude of methods and principles which have been proposed for the measurement of this elusive quantity, it is necessary only to refer to the records of the Patent Offices for the past fifteen years.

A considerable number of "Excess Meters" have from time to time made their appearance but as these instruments cannot properly be considered as coming under the head of "Demand Meters," they are not given consideration in this paper.

III. Operation on Various Loads

Provided the laws governing the mechanical operation of any type of demand meter are known, it is possible to predetermine the indications of an instrument in which the quantity measured undergoes any prearranged cycle of variations. In comparisons of demand indicators this has frequently been done, and an opportunity thus given to study the inherent characteristics of various types of demand measuring devices, particularly at the start and the finish of the duty cycle.

Under actual service conditions, however, the duty cycle is seldom exactly duplicated; and as a slight change in this cycle might produce varying effects upon the operation of different instruments, the element of uncertainty so introduced would seem to justify service tests on actual typical loads as being the only fair comparison of demand meter types.

With the object of carrying out such tests, the writer collected a number of typical instruments, all of which were installed upon an easily portable panel, so arranged as to be cut in on the metering circuits of such typical installations as were accessible. This outfit is shown in Fig. 5, there being three distinct types of meters and, of each type, four time periods. The types are as follows: Top row, Lincoln thermal storage (logarithmic); second row, Siemens (Merz type, or block-interval); third row, Westinghouse type *R. O.* (mechanically lagged).

The time periods were 10, 20, 30 and 60 minutes for the two latter types, and 10, 15, 30 and 40 for the first, it being borne in mind that the time period of a logarithmic meter is arbitrarily defined as the time required for the instrument to reach ninety per cent of its ultimate indication on a steady load. Each meter was adjusted to its maximum possible accuracy and frequently checked during the progress of the tests. The 10-minute and 30-minute logarithmic meters were supplied by the manufacturer from standard stock parts; the other periods being made up from such material as was at hand. These latter, when tested, were found to have time periods of 15 and 40 minutes respectively; which values were adopted as satisfactory for the tests.

The block-interval meters being of a pre-war European type, it was not practicable to obtain suitable timing gearings; and special methods were used. Instead of cutting new gears for the timing elements, the clocks were removed, and replaced by small solenoids operated from a contactor carried by the master clock in the continuous recording meter.

The mechanically lagged meters were stock instruments, which were fitted with suitable timing gears specially ordered from the factory.

As it is a well-known fact that none of the types of meters commercially used will infallibly measure demand upon an arithmetical basis; and as it was very desirable to have some form of instrument which could be considered as a standard of comparison, it was found necessary to develop and construct a meter for this purpose. As this meter embodies some rather unique features which may be of interest, the following description of its working principles and operation is given.

The instrument itself was built of such odds and

ends as could be found among the accumulation upon the shelves of the meter shop; and, as may be readily seen by reference to the illustration, (Fig. 6), does not partake of the general appearance of the apparatus produced by any of the well-known manufacturers of electrical equipment. However, as this device was constructed solely for experimental purposes, the use of such a nondescript instrument may be pardoned on the grounds of the interesting and satisfactory results obtained.

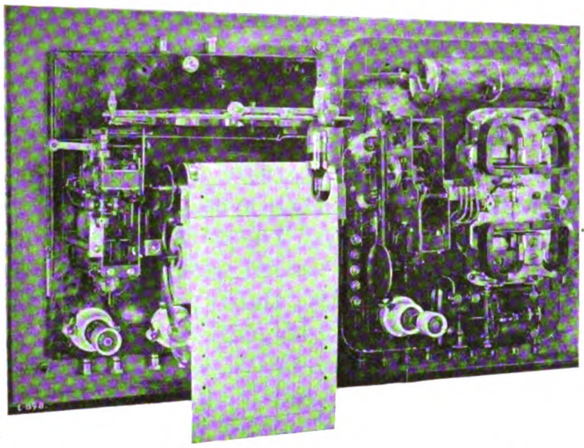

FIG. 6—CONTINUOUS RECORDING DEMAND METER

To give a clear understanding of the operation, a diagrammatic sketch is shown in Fig. 7. It will be observed that the working principle is exceedingly simple. A paper chart is caused to advance at a speed proportional to the load on the circuit, while a pen is propelled across the paper at a constant velocity in a direction perpendicular to the travel of the chart. The first motion is accomplished by means of a watt-hour meter, controlling the speed of the

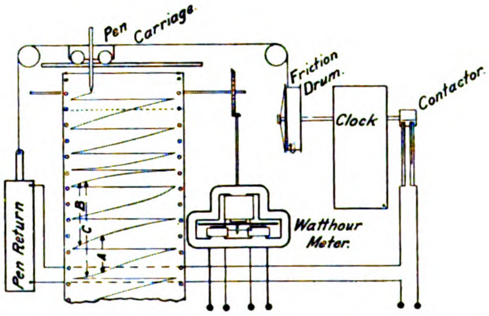

FIG. 7—DIAGRAM OF CONTINUOUS RECORDING DEMAND METER

paper travel; while the second motion is produced by a clock, winding a cord about a friction-driven drum, so that the pen makes its transit of the paper in exactly ten minutes. At the end of each ten-minute period, a contactor driven by the clock energizes an electrical device, which forcibly returns the pen to its zero position, the cord unwinding from its drum, which slips on the arbor of the clock.

As the return of the pen is practically instantaneous it will be seen that the chart takes the nature of a series of curves one above the other, the corresponding ordinates on successive curves being separated by intervals of ten minutes. It will be seen that the slope of any of the curves at any instant is proportional to the load at that instant; and the series of curves may be considered as the translated portions of one continuous curve whose height from the point of starting represents the integrated value of the load.

Since measurement along any ordinate represents the advance of the paper, *i. e.* the integrated load, during the time period between two crossings of that ordinate by the pen, it manifestly represents the average load or demand during that period. It only remains, then, for the measurement of maximum ten-minute demand, to select the ordinate whose length between two successive curves is greatest and to express its length in terms of the units measured by the integrating meter.

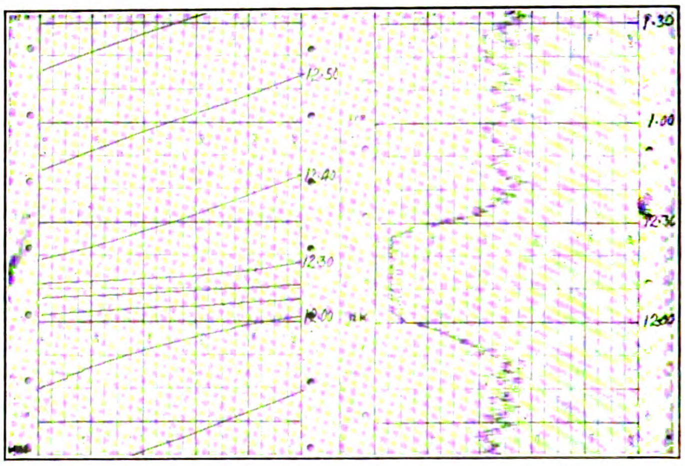

FIG. 8—SIMULTANEOUS CHARTS FROM CONTINUOUS RECORDING DEMAND METER AND CURVE-DRAWING WATTMETER

Similarly, demands for twice the normal time period of the meter may be scaled off by measuring the distance along the greatest ordinate between alternate curves; and for greater multiples of the normal period, by selecting the desired number of curves to be spanned. Thus, from the one chart it is possible to determine, not only the true maximum demand for the fundamental period, but the demand for any multiple of that period.

Referring to the chart shown in Fig. 7, the maximum ten-minute demand is indicated by the distance A, the twenty-minute demand by $B/2$ and the thirty-minute by $C/3$.

Fig. 8 shows a portion of chart from this instrument, side by side with the simultaneous record of a graphic wattmeter upon the same load. These curves illustrate the operation of the demand meter at the time of the noon valley on an actual factory load.

The portable panel carrying the demand meters and a curve-drawing wattmeter, was wired up to the metering circuits of several types of load, and careful

records were taken of the indications. These records were averaged for each meter over several days, and the averaged readings expressed in the form of curves, as shown in Figs. 9 to 14.

Since demand is one of the elements entering into the computation of load factor, and since the values of demand may vary widely, according to the method

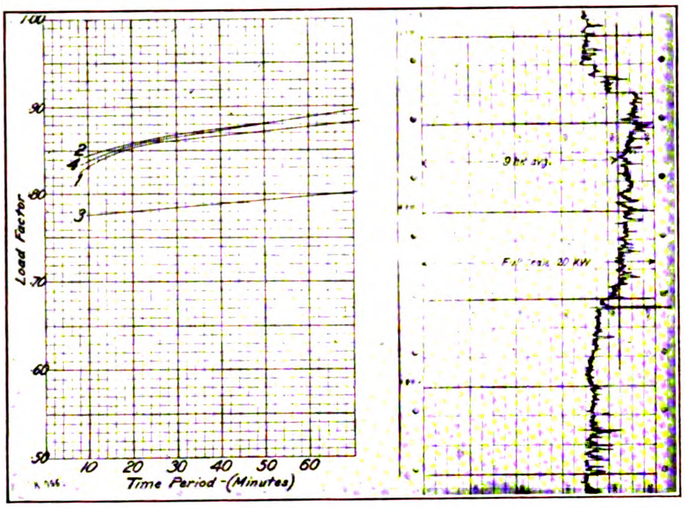

Fig. 9—Load of Electrical Testing Laboratory

of determination, it must necessarily follow that the value of load factor is subject to the same wide variations. But the latter quantity, being a ratio, and independent of the magnitude of the load, may be used in comparisons with much greater felicity than may the actual values of demand. The curves, therefore, are expressed in terms of load factor plotted

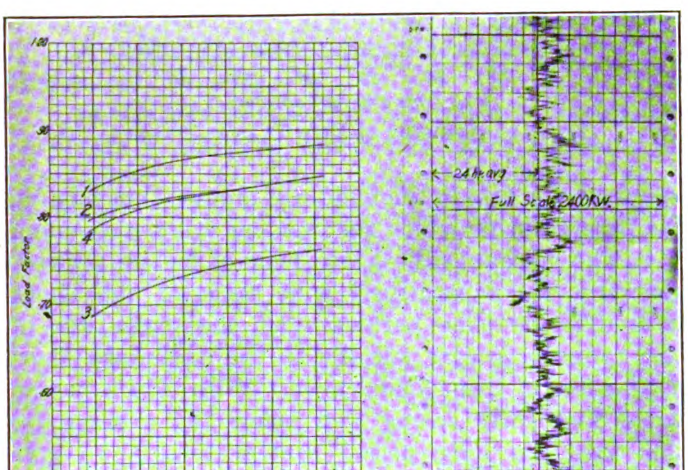

Fig. 10—Load of Rubber Manufacturing Plant

against time period, a separate curve for each type of meter and a separate set of curves for each class of load. The numbering of the curves is the same as the vertical arrangement of the meters on the panel, *viz.*—1, logarithmic; 2, block-interval; 3, mechanically lagged; 4, true arithmetical average. With each set of curves is shown a sample of graphic wattmeter chart from the same load. In the load factor calculations, the average power for the day is taken as the average over only that time during which the load curve maintained its peculiar characteristic nature.

Fig. 9 shows the values obtained with the meters installed upon the total load of an electrical testing laboratory. In this case the load was fairly steady all day, the peak occurring late in the afternoon, due to the additional power required by the lighting circuits.

Fig. 10 illustrates the curves obtained from the load of a large rubber manufacturing plant. This was a continuous 24-hour load with a deep noon valley. The peak, which was only slightly in excess of the average, usually occurred late in the afternoon.

The curves in Fig. 11 were obtained upon the feeder to a small machine shop, whose load included two

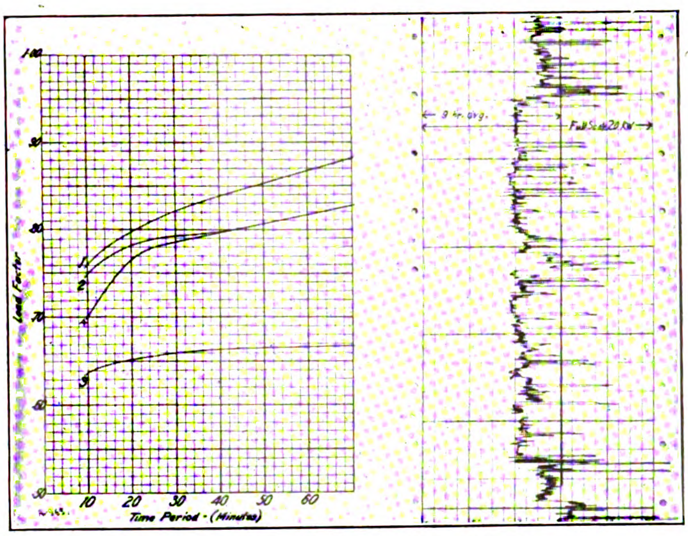

Fig. 11—Load of Smll Machine Shop

heavy freight elevators. These are responsible for the severe swings above the days average. This load is included in the load referred to in Fig. 9.

In Fig. 12, are seen the results obtained with the load of a heavy brass-rolling mill. Here are found numerous and heavy swings both above and below the average for the day.

Fig. 13 shows the curves from a city tramway load; the section investigated operating from fifteen to twenty cars. The load curve shows, even during the hours of peak load, frequent depressions approaching the zero value.

The curves illustrated in Fig. 14, are presented more as a matter of interest than for any real technical value. They are plotted from values obtained by averaging the data upon which the other five sets of curves were based. It will be observed that the several curves lie in closer proximity to one another than in any of the individual tests.

It will readily be understood that these investigations might have been carried out indefinitely upon a

great variety of typical load curves; but the results obtained on the five loads which were examined, indicate that a particular case must be made of almost every installation, and that attempts to generalize or to classify would be productive of little valuable information. Owing to the diverse nature of the results of the several tests, such facts as could be considered typical of the load curves or of the meter types can be presented only in a more or less disconnected way; and, as such, appear in the following summary.

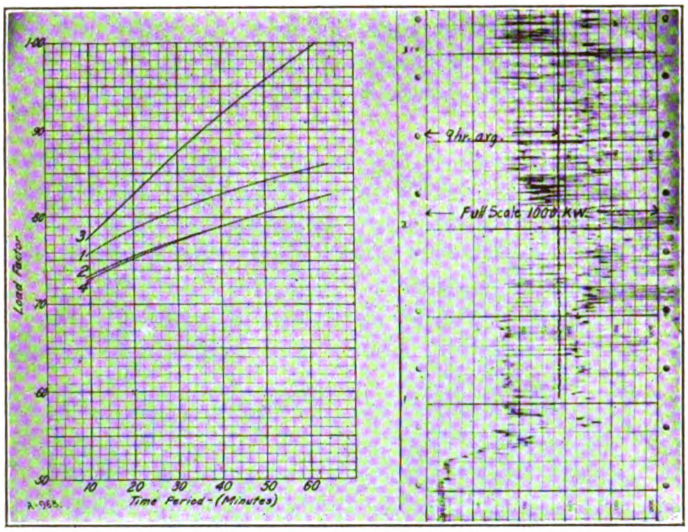

Fig. 12—Load of Brass Rolling Mill

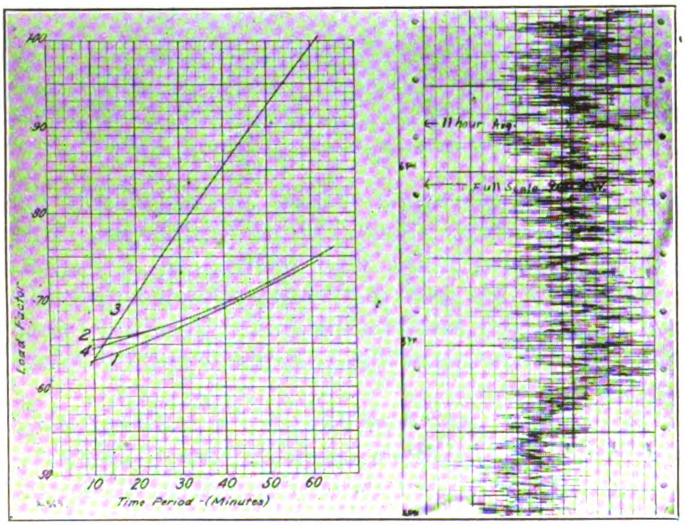

Fig. 13—City Tramway Load

Summary—Part III.

1. Except upon the most fluctuating loads, the demand meters of one type, and of differing time periods gave indications which, generally, within the limits of accuracy of the individual instruments, were in close agreement with one another.

2. The load factors as determined from day to day upon the one connected load, by a meter of one time period, differed more widely than did the values determined by the several meters of that type, upon one day's run.

3. The values of load factor as determined from readings of meters of the Merz, (or block-interval) type were found to be very erratic; and even when averaged for the one load over several days, very difficult to reconcile into a smooth curve. A higher value of load factor (*i. e.* a lower peak) was usually shown for the short periods, coming into approximate agreement with the true value of the arithmetical average, as determined by the continuous recording meter, as the time periods became longer. This phenomenon is doubtless due to the frequency with which these meters would trip in the middle of a peak, thus missing the period during which the demand was a maximum.

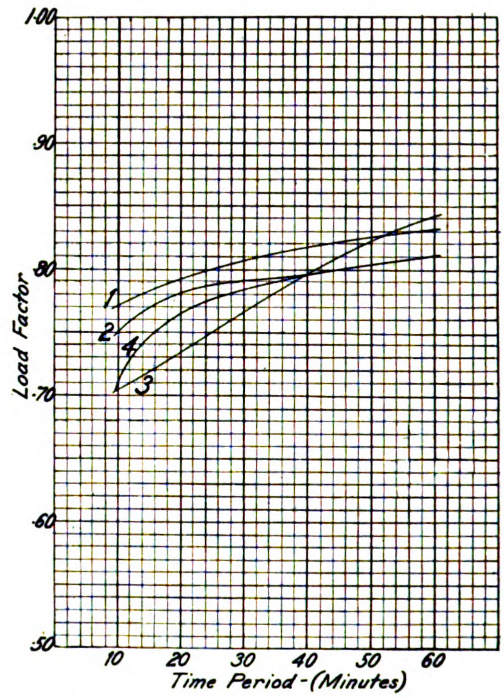

Fig. 14—Average of Five Typical Loads

4. The mechanically lagged type of meters showed, generally, a comparatively wide range of indications with differing time periods; but the magnitude of this range was very subject to the secondary characteristics of the load curve. With loads whose value frequently swung well below the average for the day, the long period meters tended to give low indications, and, consequently, high load factors; while, with loads having frequent upward swings, the reverse was usually true. Consequently these meters would sometimes show indications below the average for the day; and in several cases, on widely fluctuating loads, the 60-minute meter of this type gave load factor values of over 100 per cent. This feature is due to the fact that the timing mechanism is operative only during increasing deflections; and, upon a decrease of load below the point corres-

ponding to the position of the wattmeter element of the instrument, this element, quite irrespective of the time period of the instrument, instantly follows the load to its minimum value; and can only climb back again as permitted by the escapement.

5. The load factor, as determined by the logarithmic meters, varied, even on the most fluctuating loads, only a few per cent, between the shortest and the longest time periods.

6. With load curves wherein the peak occurred early in the day, the power having been off, or very low, during the night, the logarithmic meters tended to give readings lower than the true arithmetical peak, giving a higher value of load factor, the discrepancy approximating the difference in reading which might be expected from the "90 per cent" clause in the definition of their time period. But when the peak came late in the day, after a long-continued run, the load factor as given by the logarithmic meter approached the arithmetical load factor, and in some cases acquired a lower average value. This is consistent with the heating of electrical apparatus.

Conclusions

It is manifestly impossible to arrive at any set rules governing the selection or operation of methods or apparatus for the determination of an empirical quantity. Consideration must be given to a variety of local conditions, which, in all probability, would not be duplicated in any two power systems. It is practicable, therefore, to give as conclusions to this study only a number of deductions which will be quite evident to a student of the subject; together with suggestions as to ways and means of overcoming some of the difficulties which have heretofore presented themselves.

1. In the determination of demand it is not feasible to obtain a quantity which will fairly represent all the factors to be taken into consideration. It is probable that the most logical quantity will be found in the volt-amperes of the load.

2. Values of "sustained peak," as determined from the charts of graphic meters are frequently misleading and of little significance.

3. Values of averged or integrated peaks are difficult to measure on graphic meter charts, and are subject to a large personal error.

4. Readings of the Merz or "block interval" type of meters, though in themselves very erratic, will, in the long run, average more closely to the arithmetical average than the indications obtained by any other method.

5. Individual readings of the logarithmic meters are more consistent, and usually clcser to the true value of the arithmetical averages than are the individual readings of the Merz meters.

6. Since heating follows a logarithmic, rather than an arithmetical law, it would seem, where heating is being taken into consideration, that the logarithmic average is fully as justifiable as the arithmetical for a basis of demand measurement.

APPENDIX I.

As the tests were made with a constant voltage on the generator bus during each run it was deemed permissible for purposes of demonstration, to neglect in each case the change in voltage at the receiving end, and to consider the losses due to potential alone as being of a constant value. The expression $K\ E^m$ then becomes a constant, and may be conveniently represented by P.

The expression for the total losses then becomes $W = P + R\ I^2$, and we have only to find values for P and R. Those are easily obtained as follows: By running the system at no load, normal voltage, a value of P is at once obtained by reading the input. Subtracting this from the total power consumption at any desired value of current there is left $W - P = R\ I^2$ in which R represents the equivalent resistance of the circuit, and should be an approximately constant quantity for all values of the load.

The application of the formula with these values for P and R to the curve of amperes should give a curve representing the total losses.

A typical calculation is given below:

Watts at normal voltage, no load,	$= P$	$= 411$
Losses at chosen point	$= W$	$= 605$
Current at same point	$= I$	$= 3.31$

$$\text{Then } R = \frac{W - P}{I^2} = \frac{194}{11.0} = 17.6$$

Under ideal conditions this value, representing the equivalent resistance of the circuit, should, of course, remain nearly constant at all points of the test; but as a number of losses of secondary order have been neglected, and as the voltage was assumed to be constant at all points in the system, a variation of several per cent was, in the actual tests, noted in the value of R.

In obtaining the calculated values for the losses, there was assumed a constant value for R, this value being computed from near the middle point of the original curve, and no consideration taken of possible variations due to changes in the temperature of the copper.

An examination of the curves will show that, considering the assumptions which have been made, the calculated values of total losses check remarkably closely with the actual readings throughout the length of the curve, both on the high and the low power factor loads.

To further demonstrate the applicability of this method, a number of readings were taken at random on different types of loadings with results as shown in the following table.

Condition	W_1	W_2	$W_1 - W_2$	$R I^2 = (W_1 - W_2) - \text{Load } A$	I	I^2	$= RI^2/I^2$
A	400	000	400	000	000	000	....
B	1400	508	892	492	5.36	28.8	17.1
C	820	292	528	128	2.90	8.4	15.2
D	635	46	589	189	3.16	10.0	18.9
E	882	182	700	300	4.23	17.9	16.8
F	1064	296	768	368	4.66	21.8	16.9

W_1 = Watts input
W_2 = Watts output
$W_1 - W_2$ = Total losses
$R I^2$ = Copper losses
I = Secondary amperes
I^2 = Secondary amperes, squared
R = Equivalent resistance of circuit.

Following are the loads:
A:—No load,—excitation only
B —Lamp load only
C —Lamp load only
D —Choke coil alone
E —Choke coil and lamps in series.
F —Choke coil and lamps in multiple.

Taking the constancy of the calculated value of the equivalent resistance as the criterion by which to judge the fitness of the rule, we here find a maximum variation of 12½ per cent. A reversal of the formula and the use of resistance values having even this discrepancy would enable the values of energy loss to be computed from the current values with a far greater degree of accuracy than they could be determined from any series of readings of watts or volt-amperes of the load.

The application of such a scheme of demand measurement to determine heating effects in those portions of the system which supply only one consumer should not present any great difficulty. The two constants used in the formula could be determined for each installation; either by measurement or by calculation from the known characteristics of the lines and transformers. The application of these values to the readings of the ampere demand meter or the ampere-squared demand meter, as the case may be, would then give a check on the energy losses, and therefore, on the heating of the equipment feeding the load under consideration, thus establishing a basis upon which to compute the proportion of the overhead to be borne by that particular customer.

APPENDIX II.

In the following tables will be found the values from which were derived the curves in Figs. 9 to 13. These figures are expressed as watts in the metering circuits, no regard being given to the ratios of the instrument transformers. The values of average watts were obtained by dividing the watt-hours consumed in each day's run by the number of hours constituting the run. The maximum demands are the indications of the respective demand meters, multiplied by the proper constants and corrected for all known sources of error. Load factors were obtained by dividing the average watts for each day by the demand value for that day, as indicated by the meter under consideration. The several load factors determined by a meter of one time period and type for the several day's run were then averaged and the mean of these taken as one of the points upon the final curve.

Attention is here called to the indication of the Siemens meters occasionally being higher than the corresponding reading of the standard instrument, which would not seem in accord with the theories of that instrument. This is due to the uncertainty of the meshing of the gears, which introduced a possible error of about 1 per cent of the full scale of 300 degrees. On some occasions, when the reading was well down on the scale, this error would be greatly magnified, and increase or decrease the reading by several per cent. As all meters of this class are to a greater or less extent subject to this fault, it was taken as one of the characteristics of the type, and no effort made to correct for the inconsistency.

MAXIMUM DEMAND AND LOAD-FACTOR MEASUREMENTS ON TESTING LABORATORY

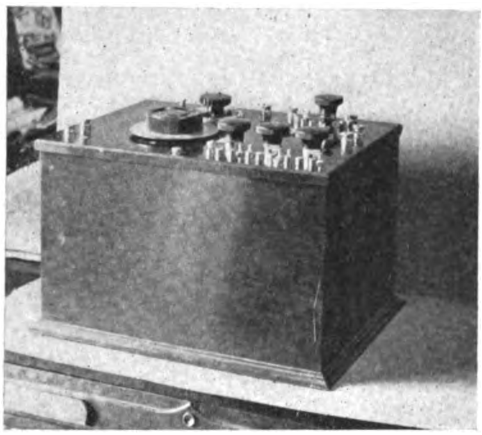
An Audio-Frequency Vacuum-Tube Generator

BY J. A. EYSTER

Electrical Laboratories, Scovill Mfg. Co., Waterbury, Conn.

The use of the three-element vacuum tube for supplying alternating current to a conductivity bridge is described and illustrated. Its advantages are set forth and the procedure which was followed in the construction of such a generator described.

IN using a Wheatstone bridge for measuring the conductivity of solutions we found that sources of alternating current such as the induction alternator and the microphone hummer did not give a pure sine wave nor anything approaching it, so that our measurement of solutions of, say 500 ohms cell resistance could not be relied upon to within more than plus or minus 1 per cent. The present available sources of alternating-current energy suitable for a



bridge are the alternator, the singing telephone or "howler", the microphone hummer, the Vreeland sine wave oscillator, the electric tuning fork and the vacuum tube oscillator. Of these the last is the only one that is capable of giving a perfect sinusoidal current, and at the same time being constant and reliable, with no moving parts and capable of a very wide range of pitch adjustment. Materials were available to set up such a generator for trial, the results of which were so encouraging that we immediately started construction of a self-contained audio-frequency generator. It is the purpose of this article to give the points of greatest difficulty in making such an oscillating set, and to emphasize the most important considerations of design.

The circuit employed was the one using close electromagnetic coupling, as it is one of the easiest to make oscillate as well as being flexible. The objects to be obtained were:

(1) A pure sine wave.

(2) Frequency continuously variable from 1000 cycles per second up to the limit of audibility.

(3) Persistency of oscillation.

(4) Power variation from zero up to several watts.

The pure sine wave is necessary, as explained above. The frequency should be continuously variable to allow tuning to the resonant frequency of the telephone receiver, and to supplement tuning with the condenser used for correcting the power factor of the conductivity bridge. Persistency of oscillation is, of course, necessary for reliability, and power variation is desirable so that the null point will be a true position of no sound, no matter what the resistance of the electrolyte. The inductance should be large and the capacitance small for two reasons, first, because the apparatus will oscillate much more easily, and second, because it is easier and cheaper to make a small capacitance which is continuously variable down to zero. We planned to make a fixed inductance and variable capacity of such sizes that with the maximum capacity the circuit would have a frequency of 1000 cycles. Variable air condensers of 0.005 microfarad capacity are on the market, and a paper condenser of ten times this capacity, variable in ten steps, and capable of standing 500 volts can be made up easily. This we did, giving a total capacity of 0.055 microfarad.

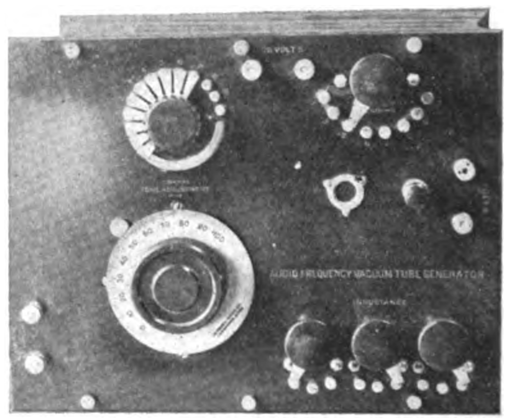
By the formula,

$$f = \frac{1}{2\pi\sqrt{LC}} \text{ (cycles per second)}$$

L is in henrys
C is in farads

the amount of inductance necessary is found to be 542 millihenrys

By experiment we found that the filament tap on the inductance should be taken out at almost exactly the two-thirds point, so we made up a coil of 2400 turns,



taking taps out after 120, 240, 1600,1680, 1760, 2160 and 2280 turns, to be sure of hitting the right point for strongest oscillations and also to give an additional method of adjusting the tone. The grid condenser used was of about 0.01-microfarad capacity, but anything from 0.01 to 2.0 microfarads will do. In order that the tube could be made to oscillate over the wide

range of frequency the grid leak was made variable, but this precaution was found not to have been entirely necessary. A 1.0-megohm leak will suffice over the useful range. The power variation is obtained simply

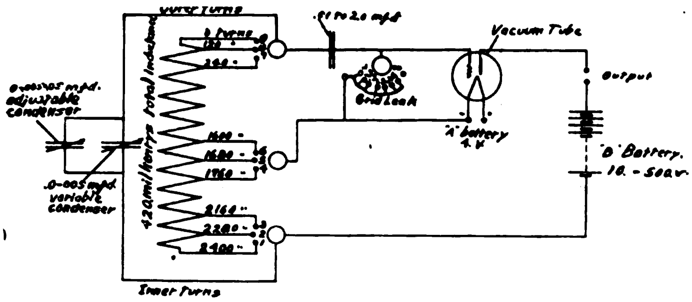


FIG. 1

by changing the "B" battery voltage and the kind of tube. For nearly all purposes the Western Electric tube known as the V. T. 1 will be satisfactory, but for greater power the V. T. 21 may be used. The

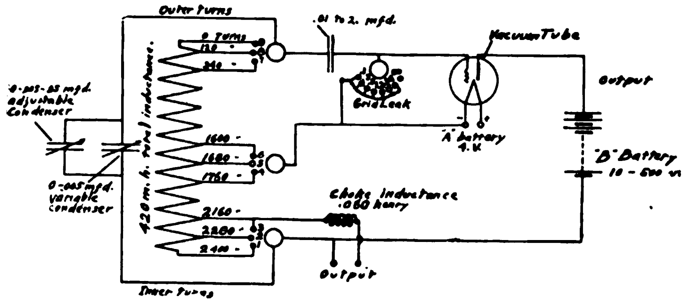

FIG. 2

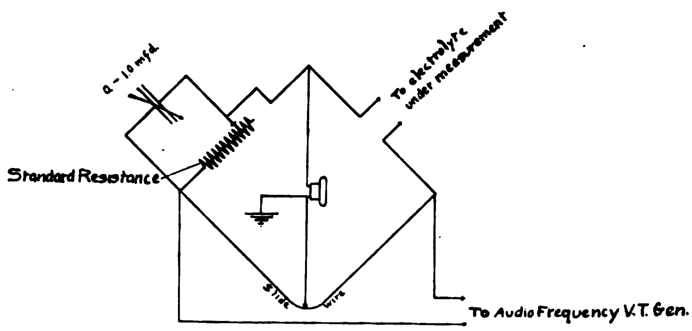
former has a maximum plate potential of 350 volts, while the latter is designed for 500 volts. In our use of this generator we find it sufficient to use the V. T. 1 with a plate voltage of 75 volts.

As shown in Fig. 1, which is the connection first used, the output is in series with the plate potential. This has several disadvantages, the main one being that the wave shape has voltage characteristics, and is not always sinusoidal. The final connection used, as illustrated in Fig. 2, gives a current wave of pure sine shape. The inductance in series with the output is primarily to prevent a low-resistance receiving circuit from short-circuiting the turns of the inductance which it shunts and stopping the oscillations. It also tends to smooth out any irregularities in the wave form which might possibly exist. If connection between the "B" battery and the bridge circuit is thought to be undesirable two 2-microfarad condensers can



Conductivity Bridge

FIG. 3

be put in the output leads, although it was not found at all necessary.

The output of this generator was observed with the oscillograph and as far as could be seen no higher harmonics existed in it, but the best test is its actual use in the conductivity bridge. There a much better accuracy was obtained than with any other source of current, and the absence of harmonics was demonstrated by the entire absence of sound at the null point. It was not hard, in fact, to measure the most unfavorable kind of electrolyte with an accuracy of plus or minus 0.1 per cent.

100,000 PETITIONS FOR METRIC SYSTEM

The Department of Commerce at Washington, D. C., is now in receipt of over 100,000 petitions from all over the United States urging upon Congress the adoption of the metric system of weights and measures as the exclusive legal standard. When Congress meets next it is anticipated that this vital question will receive extended consideration. The importance of the adoption of the metric system by the United States has been accentuated by the experience of the world war and the present need of extending the international commerce of the United States. Legislators and officials have also become alive to the increased efficiency in manufacture and production that would be made possible by the adoption of the simple decimal system of weights and measures.

Although strenuous efforts have been made by one or two organizations to stem the tide of growing metric sentiment, it is interesting to note that in contrast to the 100,000 petitions favoring metric standardization there are on file in Washington a relatively small number of petitions against this move. Not more than 1 or 2 per cent of the total number are against metric standardization. Between 98 and 99 per cent urge the advance.

Government officials whose business it has been to study this question are almost unanimous in favoring the metric system. Among staunch supporters of the metric system are William C. Redfield, Franklin K. Lane, J. W. Alexander, present Secretary of Commerce, W. B. Wilson, Secretary of Labor, Franklin D. Roosevelt, Assistant Secretary of the Navy, William G. McAdoo, John Barton Payne, and many others, including members of the Senate and House of Representatives.

A New Electrical Precipitation Treater

BY MOTOJI SHIBUSAWA and YASUJIRO NIWA

Electrical Engineers, Electrotechnical Laboratory, Tokyo

This article gives the description and theory of a new electrical precipitation treater, with results of experimental work in laboratories. The paper contains:

1. *General Description of the New Precipitation Treater; with Glass-Covered Electrodes.*
2. *Experiments at the Electrotechnical Laboratory, Tokyo, Japan.*
3. *Experiments at the Copper Refining Factory at Nikko.*
4. *Field of Practical Application of the New Precipitation Treaters.*
5. *Theory of the New Treater.*
   - *A. Potential Gradient in the Treater, Statically Solved.*
   - *B. Observed Potential Gradient in the Treater.*
   - *C. Passage of Current through the Glass.*
     - *a. Variation of Resistivity of Glass with Temperature.*
     - *b. Variation of Resistivity of Glass with Potential Gradient.*
     - *c. Free Charges on the Glass Surface.*
     - *d. Numerical Calculation on the Treater used in Oscillographic Study.*
     - *e. Conclusions.*

DURING the last ten years since the Cottrell system of precipitating dust in gases was first applied at the Selby Smelting and Lead Co. at San Francisco Bay, the system has made remarkable progress in its practical application.

It will not be amiss to describe here briefly the present extent of the application of electrical precipitation in Japan.

The following eight treaters have been built and are now working:

A. Asano Portland Cement Company (Tokyo Factory).............. 2 sets.
B. Ashio Smelter, Furukawa Mining Company.................. 2 sets.
C. Kaimoka Smelter, Mitsui Mining Company.................. 1 set.
D. Naoshima Smelter, Mitsubishi Mining Company................ 1 set.
E. Ikuno Smelter, Mitsubishi Mining Company.................. 1 set.
F. Nikko Electrolytic Copper Refining Factory, Furukawa Mining Company........................ 1 set.

The Metallurgical Research Institute, Tokyo, has the Cottrell patent rights in Japan and the comparatively rapid progress in this country is largely due to the engineers of this Institute. Beside the factories above mentioned, it is reported that the Institute has submitted designs and specifications of treaters for the Imperial Mint, Shikama Alum Factory, Kanto Sano Alkali Works, Hokkaido Iron and Steel Works and the Fujita Mining Co., etc. The details of the treaters already built are tabulated under:

In the modern precipitation treater, the electrodes consist of a metal cylinder as the passive electrode and a bare wire or a metal chain supported along the center of the cylinder as the active electrode.

In such treaters, however, the electrodes are often acted upon by corrosive precipitated particles when the system is applied for gases from smelting furnaces or other corrosive gases such as are produced in some electrochemical works; and consequently the life of the active electrode is shortened excessively; furthermore sparking often occurs between the electrodes, which prevents application to combustible substances and also sometimes causes damage to the transformer. These obstacles hinder the development of electrical precipitation, especially in its new field of application.

The authors have contrived devices in connection with the modern precipitation treater to overcome these obstacles, which have proved successful in both the laboratory and the factory.

1. General Description of the new Precipitation Treater; Treater with Glass-Covered Electrodes

The modern precipitation treater has the following demerits:

(1) The particles are more or less deposited on the active electrodes and, causing back ionization, lower the efficiency of precipitation and uneven loading of the treaters and the amputation of the active conductor by sparking.

(2) The active electrode cannot bear corrosive gas unless a certain kind of alloy wires is used.

(3) It often causes sparking between the electrodes, with subsequent troubles in operation.

In the early type of precipitation treater, sometimes insulating pieces, such as mica, are attached to the active electrode but it is not entirely covered with insulating material, and the attached pieces are used for the purpose of increasing the brush discharge and the precipitation efficiency. With this type of treater precipitation is made by surface leakage, as far as we know.

On the other hand, the fact that the air in the crevice of the power line insulator is subjected to a much higher potential gradient than when the insulating substance is absent, suggested to the authors the possibility that the high potential might ionize the air across the insulating medium of higher specific inductive capacity and that electrical precipitation might be possible even with electrodes entirely covered with insulating material such as glass, etc. The authors, therefore, carried out experiments in the Electrotechnical Laboratory in Tokyo and succeeded in their laboratory experiments, the results of which were published in November 1917, at the Faraday Convention of Japanese Electrical Society.

Recently, the system was practically applied to the treater at the Nikko Copper Refining Works where about 6500 cu. ft. of roaster gas is treated per minute, with satisfactory results.

The authors' treater, as in the case of the modern type, consists of a metal cylinder as the passive electrode and a metal wire suspended along the center of the cylinder as the active electrode; the only difference being, that the electrodes in their treater are entirely separated with dielectric substances such as glass, porcelain, etc. In the experiments at the Electrotechnical Laboratory, both the active and passive electrodes were covered with glass, but at the factory only the active electrodes were so covered.

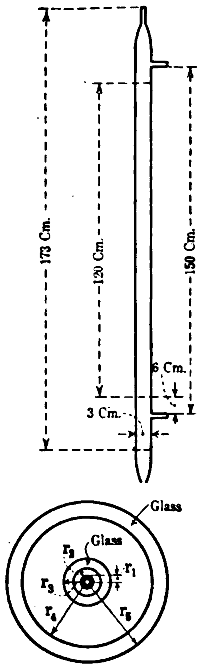

Fig. 1—Section of the Treater

r_1 = 0.35 mm.
r_2 = 1. mm.
r_3 = 2. mm.
r_4 = 14. mm.
r_5 = 15. mm.

2. Experiments at the Electrotechnical Laboratory

For the purpose of oscillographic study the following experiments were carried out at the Electrotechnical Laboratory, Tokyo.

As the active electrode a copper wire covered with dielectric material, and as the passive electrode a glass cylinder covered externally with tin foil were used. The active electrode was supported along nearly the center line of the cylinder.

Fumes of ammonium chloride were passed through this treater and a known quantity of fumes was aspirated from the side tubes attached to the upper and lower ends of the treater and the contents of chlorine were analysed, from which the precipitation efficiency was calculated.

Oscillograms were also taken in this experiment.

The dielectrics used were glass, rubber, porcelain and micanite tube, all of which gave good results, although the voltages to start precipitation were not equal owing to the difference in the nature and size of dielectrics.

The following illustrations show the result of the experiments made with glass-covered electrodes. The dimensions of the electrodes are shown in Fig. 1. Oscillograms taken are shown in Figs. 2 to 13. The circuit connection for each experiment is shown in the accompanying skeleton diagram. In every case we see more or less discontinuous increase in the current through the glass, especially remarkable in Figs. 6 and 7.

3. Experiments at the Copper Refining Factory at Nikko

Furukawa Mining Co. Ltd. has a Copper Refining Factory at Nikko, a summer resort in Japan famous for its beautiful scenery, where about 50,000 tons of copper per annum, one-third of which being drawn to wires, are electrically refined.

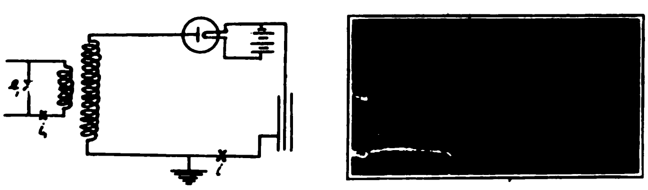

Fig. 4
Wire-positive
i = 0.2 milliampere
e = 26,000 volts.

The factory has recently installed an electrical precipitation plant in order to recover precious particles in the mixed gas from roasting cupellation, reduction and reverberatory furnaces which are used for the purpose of separating silver and gold from slimes precipitated in electrolytic baths. The treater consists of one section of 32 pipes, arranged in a rectangle 8 by 4.

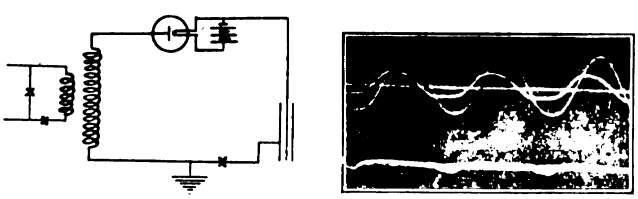

Fig. 5
Wire-positive.
i = 0.2 milliampere.
e = 26,000 volts.
Fume stopped.

These pipes, manufactured by the Western Pipe and Steel Company, are 12.5 inches inside diameter by 16 feet long and are made of No. 14 gage steel plates. The active electrode is No. 14 steel wire stretched concentrically from the lattice work. The treater was designed, at the Metallurgical Research Institute, to handle a gas volume of 8200 cubic feet per minute. But the actual volume is about 6500 cubic feet per minute and is drawn through the treater by an exhaust fan. The temperature of the gas is dependent on the furnace condition.

The roaster and cupellation furnaces are operating daily whereas the reduction and reverberatory furnaces are worked intermittently; so that the gas temperature is usually considerably below 100 deg. cent. and in the latter case only does it rise above 100 deg. cent. The electrical equipment consists of a 10-kv-a., 50-cycle, 200 to 100,000-volt transformer, manufactured by the American Transformer Company, and a rectifier of the rotary arm type, 30 inches in diameter, supplied by the Research Corporation of New York. The rectifier is driven by a 1.5-h.p., 200-volt, three-phase Westinghouse synchronous induction motor. The transformer has taps on the low-tension windings giving voltages of 50,000, 62,500, 87,500 and 100,000 on the secondary circuit. These taps, together with a rheostat in the transformer primary circuit, are sufficient to produce any desired voltage.

Fig. 14 shows an external view of the treater chamber.

From August 25, 1919 to the middle of October, the authors' devices were used in the treater at this factory. The active electrodes are covered with soda glass tubes of chemical laboratory use. The outer diameters of the tubes are 3/8 to 1/4 inch and the thicknesses 1/16

to 1/8 inch. Four such tubes were sufficient to cover the entire length of the electrode. No means for sealing the ends and junctions of the glass tubes were taken. The working results of this treater are briefly described in the following.

(1.) *Vibration of the active electrode and frequent sparking between the electrodes.* It is a well-known fact

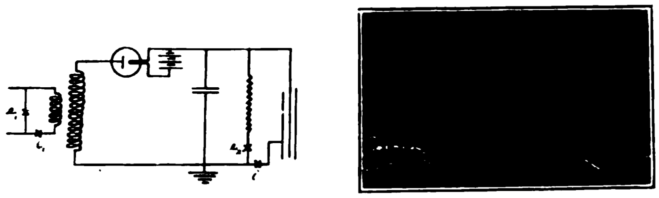

Fig. 9
Wire-positive.
i = 0.1 milliampere.
= 38,000 volts.

that the periodical static force acts on the electrodes of the treater and often causes vibration of the active electrode, especially when the electrode is more or less slackened or is not stretched concentrically; such vibration of the electrodes is one of the chief causes of sparking and consequently amputation of the active electrode. In this factory, the same troubles were

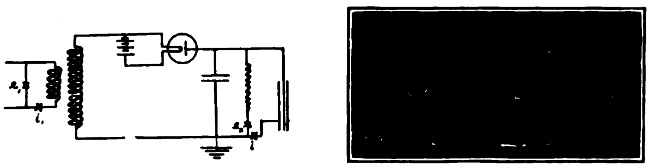

Fig. 10
Wire-negative.
i = 0.2 milliampere.
e_2 = 38,000 volts.

experienced, that is, the active electrodes were vibrated by statical force and caused much trouble.

The engineer was thus obliged to devote much time to find suitable devices to stop this vibration, and he finally succeeded in some measure; but he could not stop it completely. Nevertheless since the active electrodes were covered with glass tubes, the vibration

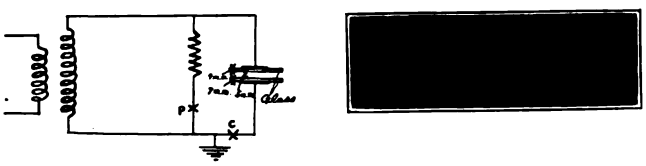

Fig. 11
Electrode area 900 cm.²
Applied voltage 20,000

had entirely ceased and practically no sparking occurred.

(2) *Deposits of dust on the active electrodes.* The dust is usually to be precipitated on the passive electrodes, for the dust deposited on the active electrodes is not easily collected in the hopper by hammering but often becomes the cause of uneven corona discharge and consequently eddies of gas around the active electrodes, and decreases the efficiency of precipitation. Therefore it is good practise to keep the deposits on the active electrode as small as possible. In this factory also much dust was deposited on the active electrodes which could not be cleaned by hammering. The authors have always been of the opinion that the deposits on

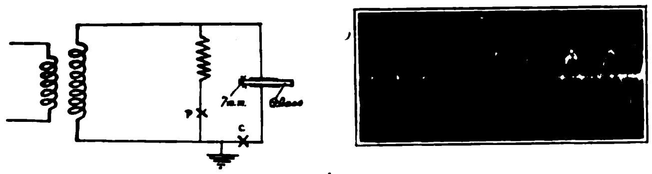

Fig. 12
Electrode area 900 cm.²
Applied voltage 18,000

the active electrodes could be considerably diminished by covering the electrodes with glass; and this has been clearly proved by the experiments at this factory. The construction of the treater chamber prevented frequent inspection of the active electrodes, but when

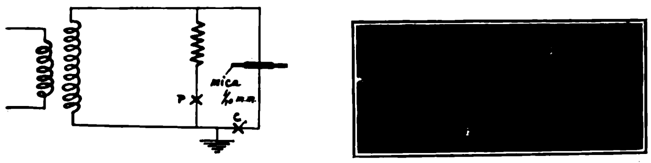

Fig. 13
Electrode area 75 cm.²
Applied voltage 5000

the electrodes were inspected two weeks after the adoption of glass-covered electrodes, it was found that they were very clean and practically no deposit was noticed on the active electrodes.

Since then, the contents of sulphuric acid in the gas

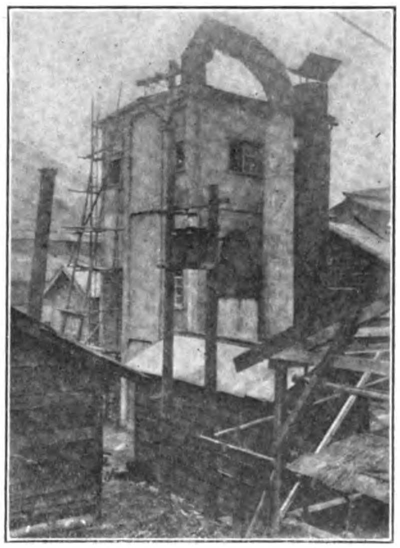

Fig. 14—External Vew of the Treater Chamber at the Copper Refining Factory at Nikko, Japan

from the furnace were increased considerably and the dust became very adhesive, and when the electrodes were inspected one month after use, the active electrodes were found to have some dust deposited on them, especially on the upper part of each electrode

near the top of the cylinder, but practically none on the lower part. The quantity deposited, was, however, very much less than when bare wire was used as the active electrode.

(3) *Corona condition.* The positive and negative corona have different features, especially in their appearance of glow. More or less evenly spaced beads are on the negative corona, whereas the positive corona has the appearance, if not roughed by points, of a smooth glow. This difference can be seen in the corona

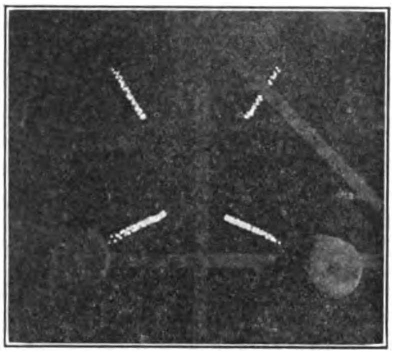

FIG. 15—NEGATIVE CORONA

around the active electrode of the treater. For negative polarity more or less evenly spaced distinct beads are seen on the wire, while for positive polarity a uniform thick glow appears as long as the wire is kept clean, but if the surface of the active electrode is spoiled the glow becomes somewhat similar to the negative corona. For bare steel wire electrodes, it is very difficult to keep the surface clean, and usually glow

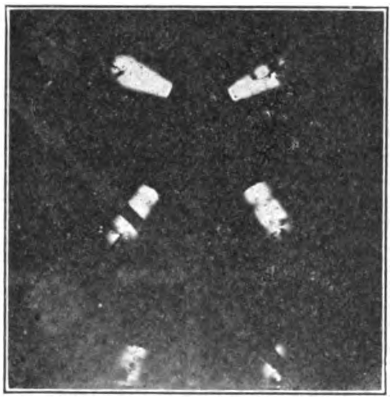

FIG. 16—POSITIVE CORONA

beads appear on the active electrodes even for positive polarity. But, since the electrodes have been covered with glass tubes, the positive glow has become very uniform and this condition has lasted for more than two weeks. Fig. 15 shows negative corona and Fig. 16 the positive corona on the glass-covered active electrodes at the working voltage. The photographs were taken one month after the use of glass covering and when the conditions were unfavorable, for the surface had been somewhat spoiled by the deposited dust, and yet almost a smooth glow can be seen all along the positive electrode.

(4) *Current, input and precipitation efficiency.* In order to test the effect of the glass covering on current, input and precipitation efficiency of the treater, the

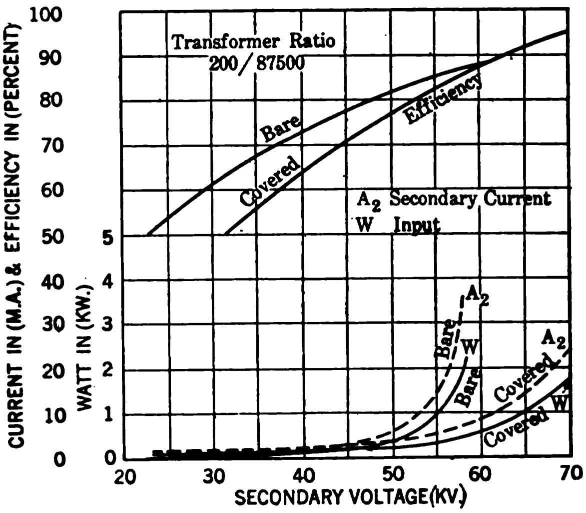

FIG. 17

following tests were made on September 26, 1919. To the treater with glass-covered electrodes, the mixed gas from two cupellation furnaces and one roaster was passed.

The temperature of the gas was 54 deg. cent. at the inlet and 38 deg. cent. at the outlet of the treater. Changing the applied voltage gradually, the corresponding current and input were measured. The precipitation efficiency was also measured with the eyes by

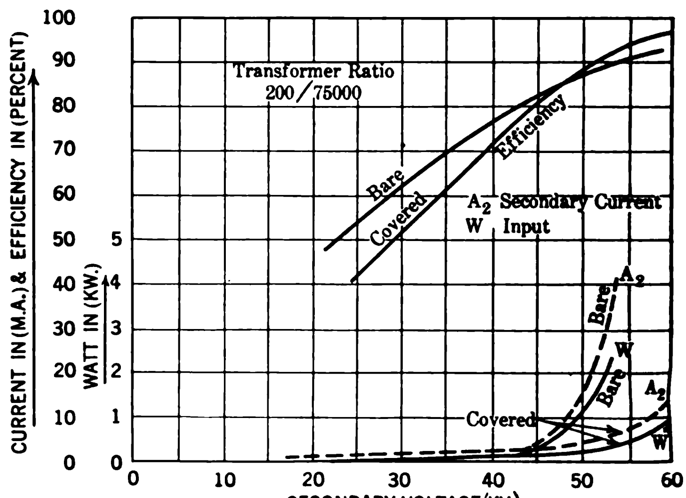

FIG. 18

an experienced engineer at the factory. These were compared with the data for a treater with bare electrodes, taken before the electrodes were covered with glass. The furnace conditions during these two experiments were of course kept as equal as possible. Figs. 17 and 18 show current, input and precipitation

efficiency as ordinates, with high-tension voltage, calculated from ratio of turns and primary voltage, as abscissas.

Comparing these two results, we find that current and input are much diminished by covering the electrodes with glass; the precipitation efficiency for the glass-covered electrodes being less than that for bare electrodes at voltages below a certain value (about 50,000 volts); but at voltages above this limit, the efficiency is much increased and moreover the final efficiency is high. Therefore we must increase applied voltage for glass-covered electrodes, and yet the current and input can be kept much below the values for bare electrodes. From Fig. 18 it will be seen that for bare electrodes at 50,000 volts, the efficiency is 87 per cent and the input 1.2 kw., whereas for glass-covered electrodes at 55,000 volts, increased by 10 per cent in voltage, the efficiency is 94 per cent and the input 0.5 kw. which shows considerable saving of power.

(5) *Conclusions.*

a. By covering the electrodes with glass, vibration of the active electrode and sparking between the electrodes are much diminished, which may prevent surging and damage to the transformer.

b. By covering the active electrodes with glass, the deposit of dust on the active electrode is much decreased; which not only facilitates maintenance, but also makes the corona discharge uniform, thus increasing the precipitation efficiency.

c. By covering the active electrodes with glass, the current and input are much diminished and also the precipitation efficiency increased. For large units of precipitation treater the power cost becomes the principal item of the running expenses, and consequently the saving of power effected by using the glass covering is assuredly a great advantage of the new treater, especially where the power cost is high.

d. One of the difficulties met with in actual operation of the modern treater is the cleaning of the deposits on the electrodes.

By the usual method such as hammering, the electrodes can not be thoroughly cleaned, especially the active electrodes, so that usually the treater is swept by hand, necessitating the workman's entering the treater.

This, of couse, is very unpleasant for the workman, especially when the precipitates contain poisonous compositions such as arsenic, selenium, etc.; so that the work is naturally shirked. By covering the electrodes with glass, precipitates on the active electrodes are considerably diminished and the necessity of frequent sweeping is obviated. Furthermore, it is possible to keep the active electrodes clean by replacing the glass covering. These are great advantages in actual operation.

e. In the experiments at the Nikko Copper Refining Factory, it was proved that the glass-covered treater could be operated successfully at a temperature below 100 deg. cent. Whether the glass can stand more than this temperature, is a question which can be determined by experiments. But excepting some special gases, such as cement kiln gas or the like, the temperature of the gas to be treated in the precipitation treater is generally below 100 deg. cent., and therefore even with the above test it shows that the glass covering may be applied for many practical cases.

f. It was feared that the glass might be broken into pieces in hammering, but this fear proved to be groundless. The covering glass showed no deterioration whatever during two months; after which period the experiments at the factory had to be stopped and the covering removed.

g. The cost of the covering glass is not an important item, for the glass to cover 32 active electrodes 16 feet long may be had for a few dollars.

The authors wish here to express their hearty thanks to Mr. S. Takenaks, the Electrical Engineer of the Copper Refining Factory at Nikko, for his kind courtesy throughout their factory experiments.

4. Fields of Practical Application of the New Precipitation Treaters

The chief merits of the new precipitation treater are enumerated below:

(1) Electrodes are not attacked by corrosive precipitates or fumes.

(2) High potential may be applied without sparking within limited space thus promoting precipitation.

(3) The active electrode may easily be kept clean, which lessens the chances of sparking.

(4) Compared with the modern type of treater, although the applied voltage must be somewhat increased current and wattage are very small and yet the precipitation efficiency is high.

Therefore the new precipitation treater, possessing these advantages is eminently suited for application in the following fields:

a. Very corrosive gases to be treated;

b. Very moist gases to be treated;

c. Dust containing combustible substances to be treated.

This new treater may thus be successfully used in order to precipitate acid particles from gases in acid works, to obtain concentric acid by spraying steam into acid gas and precipitating electrically, to precipitate inflammable materials from smelter gases and to separate cotton dust in spinning factories.

5. Theory of the New Treater

The theoretical aspect of electrical precipitation is to be attacked on the base of electrodynamical as well as electrostatical standpoint. The study of this point of view is now pursued but only the parts concerning the authors' new treater will be described here.

First of all the authors treated the potential gradient in their treater statically, and then determined experimentally the actual potential gradient in the treater.

The results showed quite different features from those calculated statically.

The most important and interesting problem regarding the authors' treater is the investigation of how current passes through glass. The authors made several experiments, which are described in the latter half of this section, to solve the question.

A. Potential Gradient in the Treater Statically Solved. The potential gradient in the treater statically solved possesses different features as compared with the actual potential gradient, and it is doubtful what practical use such solution has in the actual treater. But the suggestion of their new treater was obtained by the authors from the potential gradient statically solved in the cylinder with and without glass covering, and therefore the solution on the basis of electrostatics will be first briefly described.

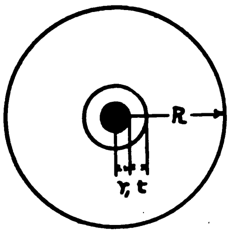

Fig. 19

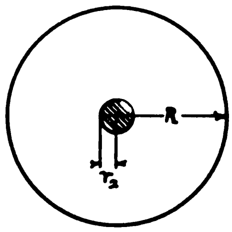

Fig. 20

First, comparison will be made of the potential gradient in the treaters with and without glass covering, a section of which is shown in Fig. 19 and in Fig. 20. The treater with glass covering will be called No. 1 treater, and the ordinary treater, No. 2 treater.

Let X_1 = potential gradient at a point X apart from the center in No. 1 treater.

X_2 = do. in No. 2 treater.

r_1 = radius of active electrode of No. 1 treater.

r_2 = do. of No. 2 treater,

R = radius of passive electrode, assumed equal for both treaters,

t = thickness of glass covering of active electrode of No. 1 treater,

K = dielectric constant of gas,

K' = dielectric constant of glass,

E_1 = applied voltage for No. 1 treater

E_2 = do. for No. 2. treater.

Then the intensities in these two treaters at the point distance X from the center are respectively:

$$X_1 = \frac{E_1}{X K\left[\frac{1}{K'}\log_e \frac{r_1+t}{r_1} + \frac{1}{K}\log_e \frac{R}{r_1+t}\right]} \tag{1}$$

$$X_2 = \left[\frac{1}{X K}\ \frac{E_2}{\frac{1}{K}\log_e \frac{R}{r_2}}\right] \tag{2}$$

If $E_1 = E_2$, then

$$\frac{X_2}{X_1} = \frac{\frac{1}{K'}\log_e \frac{r_1+t}{r_1} + \frac{1}{K}\log_e \frac{R}{r_1+t}}{\frac{1}{K}\log_e \frac{R}{r_2}} \tag{3}$$

or

$$\frac{X_2}{X_1} = 1 + \frac{1}{\log_e\left(\frac{R}{r_2}\right)^{1/K}} \log_e\left(\frac{r_1+t}{r_1}\right)^{1/K'} \times \left(\frac{r_2}{r_1+t}\right)^{1/K}$$

Therefore if

$$\left(\frac{r_1+t}{r_1}\right)^{1/K'}\left(\frac{r_2}{r_1+t}\right)^{1/K} \leqq 1$$

or

$$\left(1+\frac{t}{r_1}\right)^{1/K'}\left[\frac{r_2}{r_1\left(1+\frac{t}{r_1}\right)}\right]^{1/K} \leqq 1$$

or

$$\left(1+\frac{t}{r_1}\right)^{1/K'-1/K} \times \left(\frac{r_2}{r_1}\right)^{1/K} \leqq 1$$

Then

$$\frac{X_2}{X_1} \leqq 1$$

Usually K' (dielectric constant of glass) is greater than K (dielectric constant of gas) and therefore for equal active electrodes, or $r_1 = r_2$ above relation is always satisfied for all values of t; that is the intensity may be increased by covering the active electrode with glass. Next we will compare the maximum potential gradient in these two treaters, which, of course ought to be at the contact surface between the gas and the inner electrode. The maximum values may be obtained by putting $x = r_1 + t$ in expression (1) and $x_2 = r_2$ in expression (2). Thus

$$\frac{X_{2m}}{X_{1m}} = \frac{E_2}{E_1} \times \frac{(r_1+t)}{r_2} \times \frac{\log_e\left(\frac{r_1+t}{r_1}\right)^{1/K'}\left(\frac{R}{r_1+t}\right)^{1/K}}{\log_e\left(\frac{R}{r_2}\right)^{1/K}} \tag{4}$$

Now, suppose the applied voltage is raised until the same maximum potential gradient is attained, even with glass covering, the voltage will be given by, equating expression (4) to unity, thus

$$E_1 = \left(\frac{r_1+t}{r_2}\right)$$

$$\times \frac{\log_e\left(\frac{r_1+t}{r_1}\right)^{1/\kappa'}\left(\frac{R}{r_1+t}\right)^{1/\kappa}}{\log_e\left(\frac{R}{r_2}\right)^{1/\kappa}} \times E_2 \quad (5)$$

Applying these voltages to each treater respectively, the ratio of the potential gradients at any point of both the treaters equidistant from the center becomes

$$\frac{X_2}{X_1} = \frac{\log_e\left(\frac{r_1+t}{r_1}\right)^{1/\kappa'}\left(\frac{R}{r_1+t}\right)^{1/\kappa}}{\log_e\left(\frac{R}{r_2}\right)^{1/\kappa}} \times \frac{E_2}{E_1} \quad (6)$$

Substituting (5) in (6) we have

$$\frac{X_2}{X_1} = \frac{r_2}{r_1+t} \quad \text{or} \quad X_1 = \frac{r_1+t}{r_2} \times X_2$$

Thus by raising the applied voltage in No. 1 treater to

$$\left(\frac{r_1+t}{r_2}\right)\left[\frac{\log_e\left(\frac{r_1+t}{r_1}\right)^{1/\kappa'}\left(\frac{R}{r_1+t}\right)^{1/\kappa}}{\log_e\left(\frac{R}{r_2}\right)^{1/\kappa}}\right] \quad (5)$$

times the voltage in No. 2 treater, we may increase the potential gradient in the gas in No. 1 treater by $\frac{r_1+t}{r_2}$ times the value in No. 2 treater, keeping the maximum potential gradient at constant.

But the expression in the large brackets in (5) is the same as (3) which is less than unity for equal active electrodes and for all values of t, which means that the potential in the No. 1 treater is increased, keeping the maximum potential gradient constant, by a ratio more than the value by which we raised the applied voltage.

One more important item to be considered is that with the glass covering there is less chance of sparking between electrodes and thus we may conclude that the intensity in the treater may be increased, keeping the maximum potential gradient at constant, with a safer condition with regard to the sparking between electrodes.

In Fig. 21 A is the potential curve in the treater with

r_1 = 0.45 mm.
R = 15 mm.
K = 1
E = 10,000 volts.

When the active electrode of this treater is covered with the dielectric substance of thickness 0.95 mm. having a dielectric constant of 2.5, the potential gradient in the treater will become as shown in curve B. Now, in order to increase the maximum potential gradient in the gas to the same value in curve A, the applied voltage must be increased to 32,000 and the corresponding potential gradient is expressed in curve C, which shows that the potential gradient in the gas is much increased as compared with the curve A.

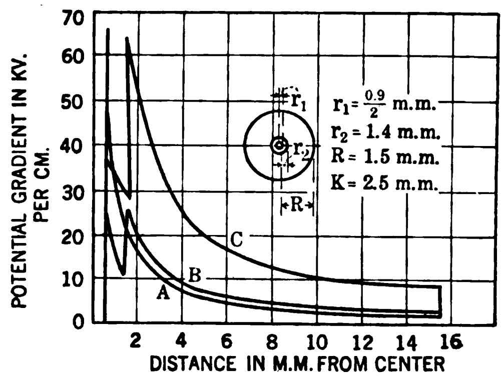

Fig. 21

B. Observed Potential Gradient in the Treater.

The electrical precipitation is done by the migration of charged particles and the presence of charged particles in the treater necessarily changes the potential gradients in the treater.

In order to obtain the actual potential curve in the treater, the authors made the following experiment. The connection diagram of the experiment is shown in Fig. 22.

T is the 100-160,000-volt, 20-kv-a. testing transformer; K, the 40,000-volt kenotron made at the Electrotechnical Laboratory; and U, the treater with glass covering, a section of which is shown in

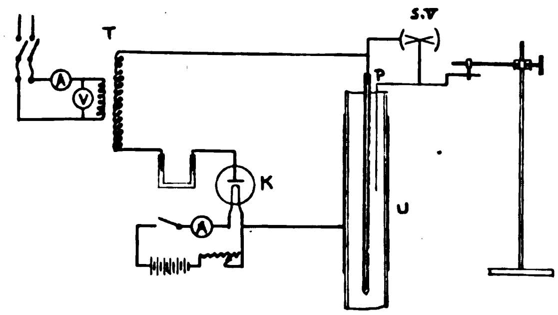

Fig. 22

Fig. 24A. One end of the glass tube being sealed, salt water was poured into it and used as the active electrode. As the passive electrode, tin foils stuck to the outer surface of the glass tube were used.

High voltage was applied to the treater through the kenotron, and a Kelvin static voltmeter (s. v.) was connected between the active electrode and the pointer, P, which was gradually displaced by turning the pulley, from the active to the passive electrode, keeping always parallel to the electrodes. The mechanism is shown in Fig. 23. The potential difference between the active electrode and any point in the treater was

measured by the static voltmeter. In this manner the potential curves in the treater were obtained; one of these curves which corresponds to the maximum voltage of 8500 is shown in Fig. 24. The potential gradient curve in the treater was obtained from the potential curve, which has different features from the curve calculated statically. As the reading of the static voltmeter is the square root of the mean of the

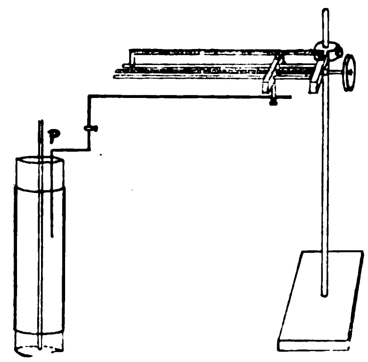

Fig. 23

half wave taken over the whole period, correction was made assuming the wave sinusoidal. Let E and E_m be the voltmeter reading and the maximum voltage

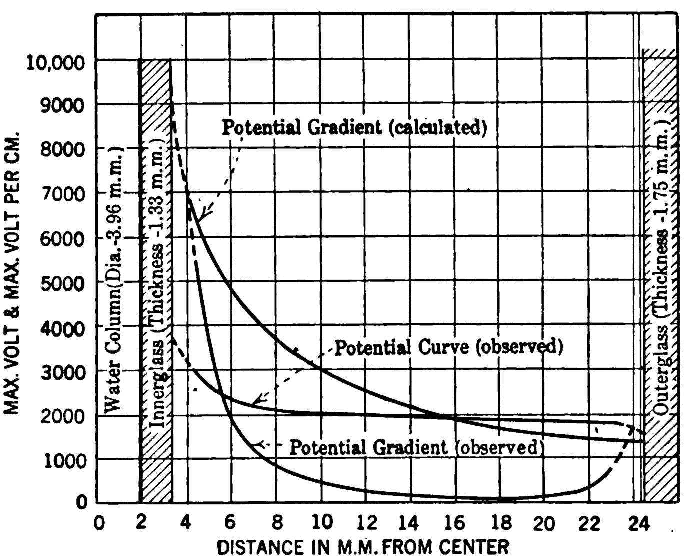

Fig. 24

respectively; then

$$E^2 = \frac{1}{2\pi}\int_0^{\pi} E_m^2 \sin^2\theta \, d\,\theta$$

$$\text{or} \quad E^2 = \frac{E_m^2}{2\pi} \times \frac{\pi}{2} \qquad \therefore \quad E_m = 2E.$$

In Fig. 24 the pulsating voltage is expressed in its maximum value using this correction factor. As may be seen in the figure existence of the charged ions or particles in the treater causes a zone of high potential gradient at the boundary of the passive electrode, and lowers the potential gradient in the space between the electrodes. As the pointer used in this experiment had a diameter of 1 mm., the potential difference at the extreme boundary to the electrode will be higher than the value in Fig. 24. Moreover, the capacity of the static voltmeter, although very small, will disturb the condition, and may introduce some error in the results.

Mr. H. T. Booth published also an experimental result upon the potential curve for the treater without glass covering which shows the same feature as that in Fig. 24. (cf. Distribution of Potential in a Corona Tube. *Physical Review.* Sept. 1917.)

C. Passage of Current through the Glass.

In the early experiments on their treater the authors found that the current through the glass was much larger than the value calculated from the potential gradient in the glass and the resistivity of the glass given in the text-books. Why so large a current is

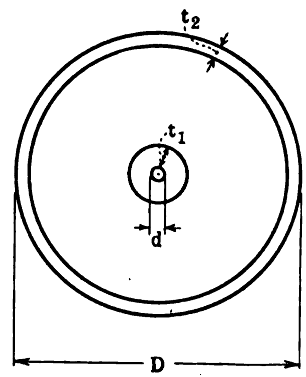

Fig. 24a

d = 3.96 mm.
t_1 = 1.33 mm.
t_2 = 1.75 mm.
D = 26.06 mm.

permitted to flow through the glass and enables electrical precipitation with glass-covered electrodes is the most important and interesting problem regarding their treater.

On this question the authors made the following experiments.

a. Variation of Resistivity of Glass with Temperature. In order to determine the effect of temperature upon the resistivity the following experiment was made in the Electrotechnical Laboratory, Tokyo. The connection is shown in Fig. 25. T is the high-voltage transformer; K, the kenotron with which high-voltage alternating current is rectified; A_m, sensitive d-c. millivoltmeter of permanent magnet type; G, the glass tube the resistivity of which was to be measured. One end of the glass tube was fused and the tube was filled with mercury and tin foils were stuck to the outer surface of the tube at the middle part of the whole length. The mercury and the tin foils were used as the electrodes. The tube was put into an oil bath and the temperature of the bath was gradually

changed, keeping the voltage constant; and the corresponding current through the glass tube was measured.

The tube tested was ordinary soda glass commonly used in chemical laboratories such as for the inlet pipe of wash bottles.

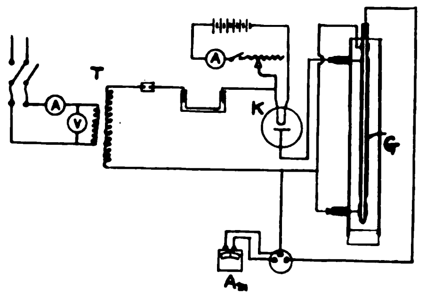

Fig. 25

The dimensions of the tube are shown below:

inner radius r_1.......	=	0.220	cm.
outer radius r_2.......	=	0.311	"
thickness t...........	=	0.091	"
length of tube.......	=	105	"
length of foil covering	=	65	"

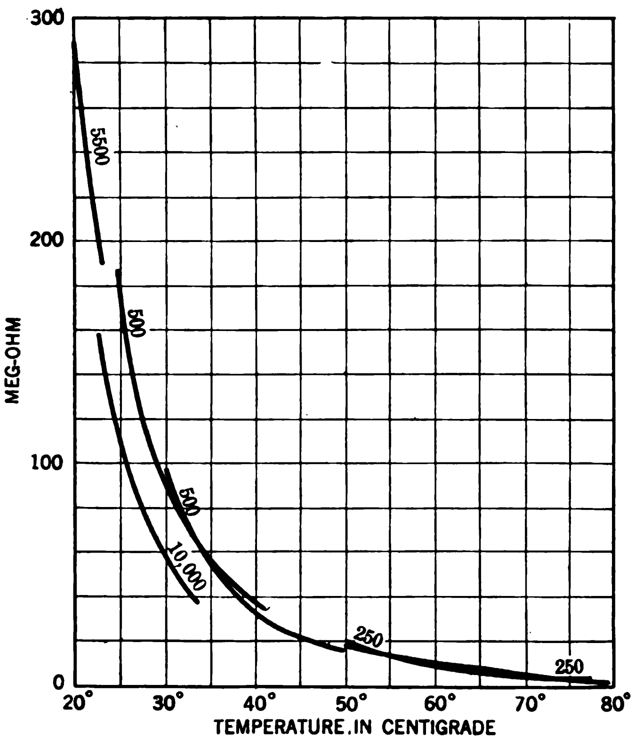

Fig. 26

As the guard ring prevents surface leakage, the millivoltmeter indicates the current through the glass only. Fig. 26 shows the results of several experiments. Here, as the ordinates, the apparent resistance of the tube (ratio of voltmeter readings to the readings of ammeter A_m multiplied by transformer ratio) and as the abscissas, the temperature in degrees centigrade were taken. As may be seen from the figure, the curves for 500 and 250 volts are nearly coincident, while curves for 5500 volts and 10,000 volts are respectively under the above curve although they have the character of a similar nature. The logarithmic values are plotted in Fig. 27, which lie nearly on respective straight lines.

The reading of the voltmeter denotes the effective value of the electromotive force, *i. e.* $\frac{1}{\sqrt{2}}$ of the

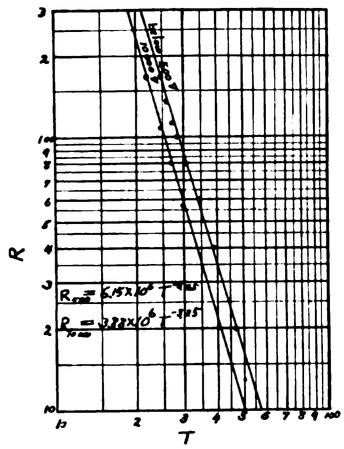

Fig. 27

maximum value, and the reading of the permanent magnet d-c. millivoltmeter, is the mean value of the half wave taken on the whole period and equal to $\frac{1}{\pi}$ of the maximum value. Taking this into ac-

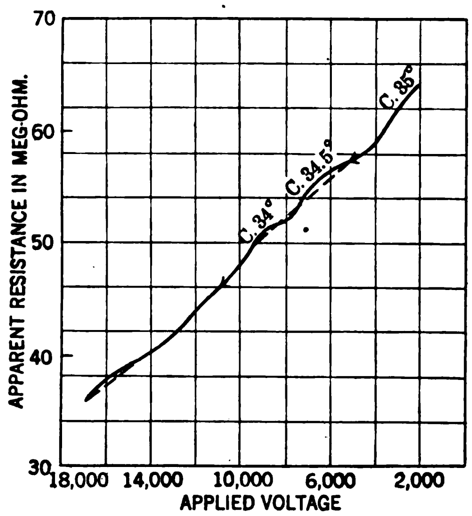

Fig. 28—"B" Glass Tube in Oil Bath—Applied Voltage-Resistance Curve

count and with the aid of Fig. 27, and the formula

$$R = \frac{\rho}{2\,\pi\,l}\log_e\frac{r_2}{r_1}$$, we get the resistivity as follows:

$$\rho = \frac{3.28 \times 10^9}{T^{3.25}}$$

(for applied voltage below 500 and temperatures between 25 deg. cent. and 80 deg. cent.)

$$\rho = \frac{2.06 \times 10^9}{T^{3.25}}$$

(for applied voltage 10,000 and temperatures between 20 deg. cent.) and where ρ is resistivity in megohm-cm. and T temperature in degrees centigrade.

b. Variation of Resistivity of Glass with Potential Gradient. In order to determine the effect of the potential gradient on the resistivity of glass, the authors made the following experiments.

The apparatus used and the connections were the same as the experiment for (a). The applied voltage was gradually changed and the millivoltmeter reading as well as the temperature of the oil bath was taken. Fig. 28 is the resistivity-potential curve for the same glass tube as in the experiment (a). Here the abscissas are the primary voltage multiplied by the transformer

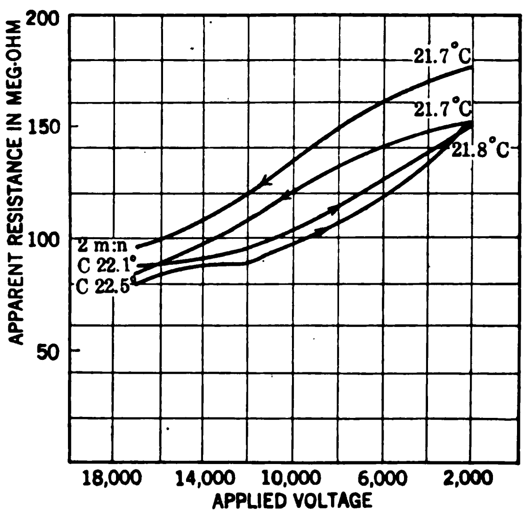

FIG. 29—"D" GLASS TUBE IN OIL—APPLIED VOLTAGE-RESISTANCE CURVE

ratio and the ordinates are the apparent resistance ratio of the readings of voltmeter (V) to that of the ammeter (Am) times transformer ratio. The potential gradient in the tube is not uniform and is given by

$$G_x = \frac{e}{x \log_e \dfrac{R}{r}}$$

while the mean value is

$$G_{mean} = \frac{1}{R - r} \int_r^R \frac{e\,dx}{x \log_e \dfrac{R}{r}} = \frac{e}{R - r} .$$

Therefore the potential gradient at the inner and outer sides of the tube at the mean potential gradient for 1000 applied volts is as follows:

$$G_{outer} = \frac{1000}{0.311 \log_e \dfrac{0.311}{0.220}} = 9307 \text{ volts per cm.}$$

$$G_{inner} = \frac{1000}{0.220 \log_e \dfrac{0.311}{0.220}} = 13{,}160 \text{ volts per cm.}$$

$$G_{mean} = \frac{1000}{0.311 - 0.220} = 11{,}000 \text{ volts per cm.}$$

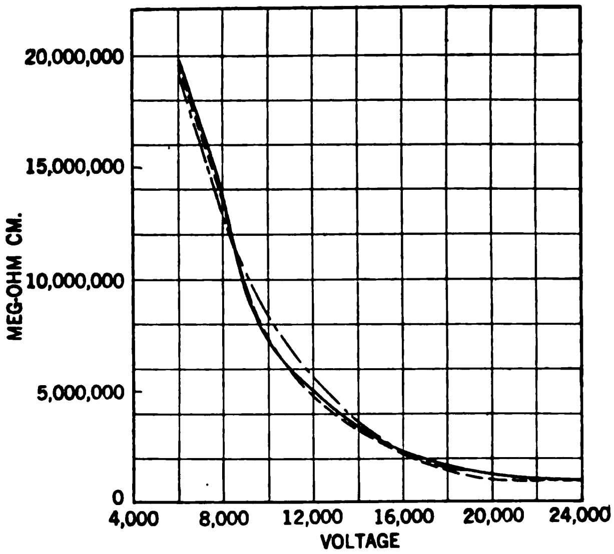

FIG. 30—"JENA" GLASS TUBE—APPLIED VOLTAGE AND SPECIFIC RESISTANCE CURVE

inner diameter 0.1128 cm.
outer diameter 1.0000 "
thickness 0.4432 "
effective length 34.0000 "

Fig. 29 shows the curve for another glass tube.

As may be seen from the curves the values of resistivity in the increasing voltage are higher than those in decreasing voltage, which may be the effect of the

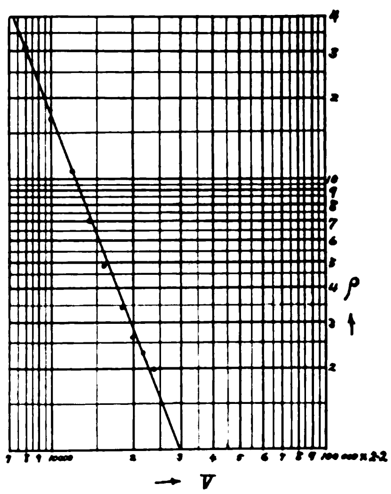

FIG. 31

temperature. Therefore the decrease of resistivity with the potential gradient may be partly due to the increase of the internal temperature.

Thus whether the decrease of resistivity of glass with the potential gradient is the direct effect of potential gradient or indirect effect of the heat in the glass due

to the ohmic loss is now in question, but for our purpose, it is sufficient to know that the resistivity of glass decreases with the potential gradient; the reason will be left for further study.

Fig. 30 shows the results of the same experiments with the Jena glass, which is to be used for the resistance standard.

The dimensions of the tube are

inner diameter.....................0.1128 cm.
outer diameter.....................1.000 "
thickness.........................0.4436 "
length of tin-foil covering......34.00 "

With the same circuit diagram as Fig. 27 the relation between the resistivity and the applied voltage was measured. In this experiment the oil bath was not used and the measurement was made at room temperature, 17 deg. cent.

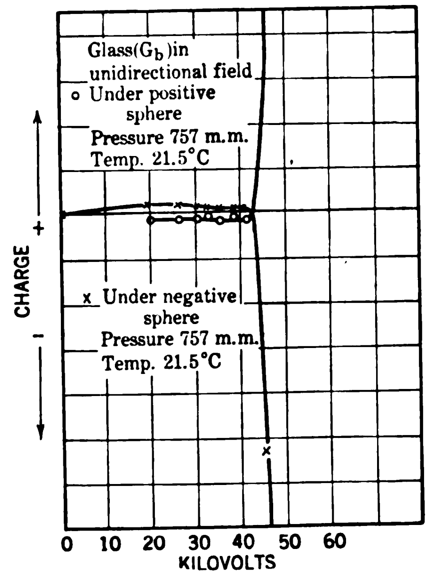

FIG. 32A

The voltage was gradually increased and then decreased, and this was repeated for several cycles. The results are represented by a curve as shown in Fig. 30, which does not show a hysteresis as in Fig. 29, which may be attributed to the superior quality of the Jena glass.

The resistance and the applied voltage have a logarithmic relation to each other as seen in Fig. 31, from which we may derive the relation between resistivity and the applied voltage in the same manner as in the calculation of resistivity from Fig. 27. Thus

$$\rho = 2.9 \times 10^9 \, V^{-2.60} \quad (V \text{ in kv.})$$

The potential gradient at the inner and outer sides of the tube and the mean potential gradient for applied voltage of 1000 are:

$$G_{inner} = \frac{1000}{0.1128 \log_e \dfrac{1.000}{0.1128}} = 4064 \text{ volts per cm.}$$

$$G_{outer} = \frac{1000}{1.000 \log_e \dfrac{1.000}{0.1128}} = 465 \text{ volts per cm.}$$

$$G_{mean} = \frac{1000}{1.000 - 0.1128} = 1130 \text{ volts per cm.}$$

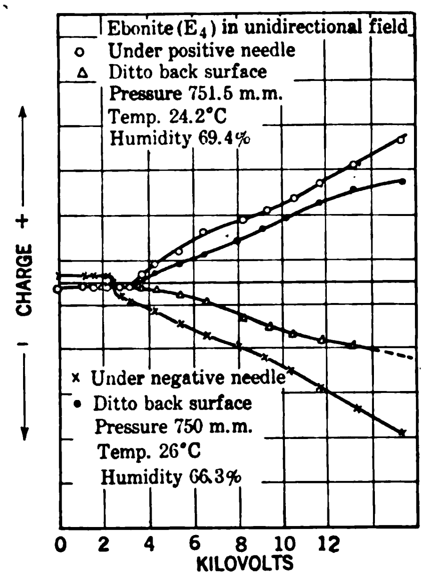

FIG. 32B

Using the mean potential gradient (G_m) as parameter, the resistivity may be expressed as

$$\rho = 4.0 \times 10^9 \, G_m^{-2.60}$$

where ρ is the resistivity in megohm-cm. and G_m is the potential gradient in kv. per cm. for the range between $G_m = 7$ and 27.

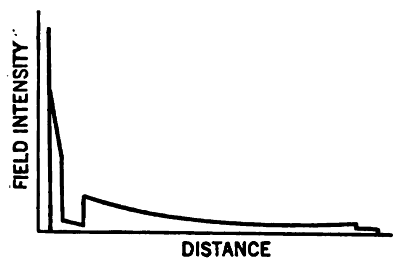

FIG. 33

c. Free Charges on the Glass Surface. Mr. Nishi, Assistant Professor at the Imperial University of Tokyo, published a part of his research on dielectrics in the *Journal of Electrical Society of Japan*, February, 1920. He found that the definite free charge appears always on the surface of the dielectrics, placed in an electric field, after the field is removed. Fig. 32 shows the curves for glass and for ebonite, taken from his paper. The glass or ebonite plates were placed between sphere or needle and plate electrodes, and at a given potential difference between electrodes the free charge appearing on the surface of the dielectric was measured with a sensitive ballistic galvanometer

or quadrant electrometer after the potential was removed. In unidirectional field, free charge of the polarity opposite to that of the electrode appears on the surface below a certain limit of potential difference, above which the sign of the polarity changes. Taking these experimental results as basis Mr. Nishi derived a theory for the authors' precipitation treater as follows:

Take, for instance, the treater, the section of which, is shown in Fig. 1. Fig. 33 shows the potential gradient curve of it calculated statically. Assume the active electrode be taken as negative, then the negative charge will appear on the inside surface of inner glass covering and the positive charge on its outside surface, and the negative charge on the inside surface of outer glass covering. As the results of these charges, the potential gradients in the glass will be much higher than the value calculated statically and the gradient in the air will be decreased by the appearance of free charges on the dielectrics. The supposed potential gradient curve may be shown as in Fig. 34 instead of Fig. 33. This high-potential gradient in the glass combined with the diminution of resistivity of glass with temperature and potential gradient will be sufficient to permit an unexpectedly by large current to flow through the glass.

d. Numerical Calculation on the Treater used in Oscillographic Study. In the oscillographic study we get 0.2 milliampere of the current through the treater, the section of which is shown in Fig. 1, by applying 26,000 volts. (cf. Fig. 2.)

Now taking the resistivity of glass obtained by the two experiments above mentioned, we will calculate the potential difference at the two surfaces of inner glass covering and those of outer glass covering, in order to cause the passage of 0.2 milliampere of current.

The resistances of inner and outer glass coverings are

$$R_{inner} = \frac{\rho}{2\pi l} X \log_e \frac{r_3}{r_2} = \frac{\rho}{2\pi \times 120} \log_e \frac{2}{1}$$

$$= 0.92 \times \rho \times 10^{-3}$$

$$R_{outer} = \frac{\rho}{2\pi l} \log_e \frac{r_5}{r^4} = \frac{\rho}{2\pi \times 120}$$

$$\times \log_e \frac{15}{14} = 0.90 \times \rho \times 10^{-4}$$

Taking the resistivity of glass at

$$\rho = \frac{2.06 \times 10^9}{T^{3.25}}$$

and assuming the temperature at 30 deg. cent we get

$$R_{inner} = 0.92 \times 10^{-3} \times \frac{2.06 \times 10^9}{(30)^{3.25}}$$

$$= 28.9 \text{ megohm.}$$

$$R_{outer} = 0.90 \times 10^{-4} \times \frac{2.06 \times 10^9}{(30)^{3.25}}$$

$$= 2.8 \text{ megohm.}$$

Therefore in order to cause 0.2 milliampere of current to pass the potential differences must be

$$V_{inner} = 5780 \text{ volts.}$$

$$V_{outer} = 567 \text{ "}$$

The authors are of the opinion that the pure statical treatment on the electrical precipitation treater must

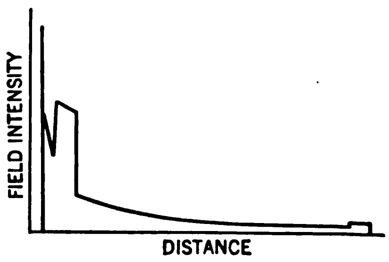

Fig. 34

have very little value but in order to give a rough idea, these values will be compared to the calculated values assuming the treater as a pure cylindrical condenser.

The potential gradient in the treater, when considered as a cylindrical condenser, is given by the formula;

$$G = \frac{E}{X K \left[\log_e \frac{r_2}{r_1} + \frac{1}{K} \log_e \frac{r_3}{r_2} + \log_e \frac{r_4}{r_3} + \frac{L}{K} \times \log_e \frac{r_5}{r_4} \right]}$$

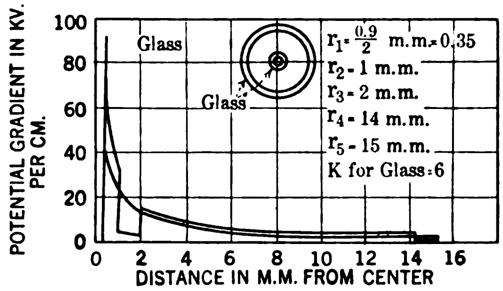

Fig. 35

and is shown in Fig. 35 for the applied voltage of 10,000. The potential differences at two surfaces at inner and outer glass covering where 26,000 volts are applied between two electrodes are as follows:

$$V_{inner} = \int_{r2}^{r3} g_x \, dx = 960 \text{ volts}$$

$$V_{outer} = \int_{r4}^{r5} g_x \, dx = 93 \text{ volts}$$

These values are nearly one-sixth of the values, necessary to cause 0.2 milliampere to pass; the difference may be due to the effect of the free charge on the glass surface and the existence of charged particles

in the space of the treater etc. As shown in the above paragraph, the actual potential gradient in the glass will be much higher than the value calculated statically; but, unfortunately the amount of this increase cannot be calculated quantitatively, still, the authors believe that the increase of the potential gradient to the value a few times the statically calculated one is possible and the current found in the laboratory experiment will be easily allowed to pass through the glass.

e. Conclusions. As to the reason why so large a current is permitted to flow through the glass and enables electrical precipitation with glass-covered electrodes, the authors conclude as follows:

(1) Resistivity of glass decreases with temperature as well as with potential gradient applied.

(2) Free charge appears on the surface of the glass placed in the electric field, which causes, in the dielectrics, a potential gradient much higher than that calculated by mere statical consideration.

(3) As the current necessary for the electrical precipitation is very small, the above mentioned two causes permit a sufficient current to enable electrical precipitation to flow through the dielectrics.

A Simple Harmonic Analyser

BY V. BUSH.

Massachusetts Institute of Technology, and Consulting Engineer, American Radio & Research Corporation

THIS paper describes a new mechanical integrator which it is hoped will fill a need, particularly among electrical engineers, for a simple inexpensive device of this nature.

It will evaluate the integral

$$\int f(x) \sin(\omega x + \beta)\, d x$$

where $f(x)$ is any known single valued function. Thus its principal use will be the determination of the harmonics of an irregular function, such as the problem of splitting an oscillograph curve of current or voltage into its components. It may be useful also in other connections in which the above integral occurs, as for instance in Carson's extension of Heaviside's expansion theorem for determining the alternating from the constant potential solution of transients in a network.*

Schedule methods of harmonic analysis are usually laborious and often not highly accurate, particularly where a single high harmonic is desired. There are many forms of mechanical integrators for this purpose, some of which are excellent, but they are usually too expensive for the small engineering office or laboratory. Chubb's polar form is particularly useful in connection with a polar ocsillograph, but it is inconvenient in other connections, and quite complicated. The Coradi analyser is probably the most convenient machine, since it works in rectangular coordinates and determines several components simultaneously. Very few of these instruments are in use, however, because of their cost. The present instrument is quite similar in theory to several forms which have been proposed, but it has been simplified mechanically.

The analyser consists of a set of transparent disks, preferably of celluloid, a planimeter of any convenient form, and a piece of silk fish line. The disks are prepared as shown in Fig. 1. The edge is grooved to a diameter d, or more exactly to a diameter less than this chosen value by the thickness of the line used. The upper surface carries two depressions, A and B, connected by a straight trough. A is at the center of the disk, and B preferably at a radius $d/2$, although B may be placed elsewhere if desired and correction made by a constant factor. In the center of the bottom surface of the disk is a dot. The disk is graduated in angles, clockwise from the trough, the marks being preferably on the lower surface.

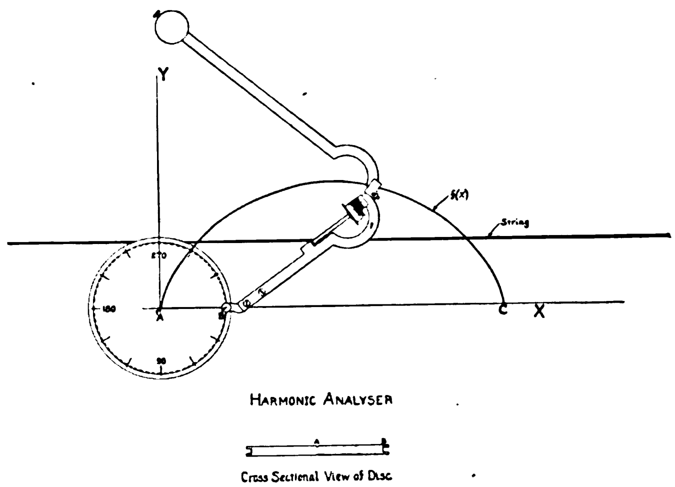

FIG. 1

The instrument is set up for use as follows. The curve to be analysed is plotted to a convenient scale in rectangular coordinates, and placed in the center of a long table. A disk of size corresponding to the desired component is placed on this plot. The length of a complete period of the plot divided by πd will give the order of the harmonic which will be obtained. In other words, if a disk of diameter d is to be used, and the nth harmonic is desired, a scale for the plot

*John R. Carson, PROC. A. I. E. E, March, 1919.

should be chosen such that a period of the curve covers a distance $\pi d n$. The line is then given a single turn clockwise about the disk, fastened to the ends of the table and pulled fairly taut. The plot is now fastened down with the horizontal axis parallel to the line. This set up is shown in Fig. 1 and Fig. 2. By placing a sharp point in A, the disk may now easily be moved over the plot. When moved vertically it will not rotate; but when moved horizontally it will turn through an angle proportional to the distance moved. The disk may be moved over an ordinate near each end of the plot, and the constancy of the angular scale reading of the ordinate noted to check the alignment; and the scale of the plot may be checked by moving the disk horizontally over a period and noting that it makes the correct number of revolutions. Of course, as with any such integrator, symmetry may be made use of and a plot of one-half, or even one-quarter of a period of the curve utilized.

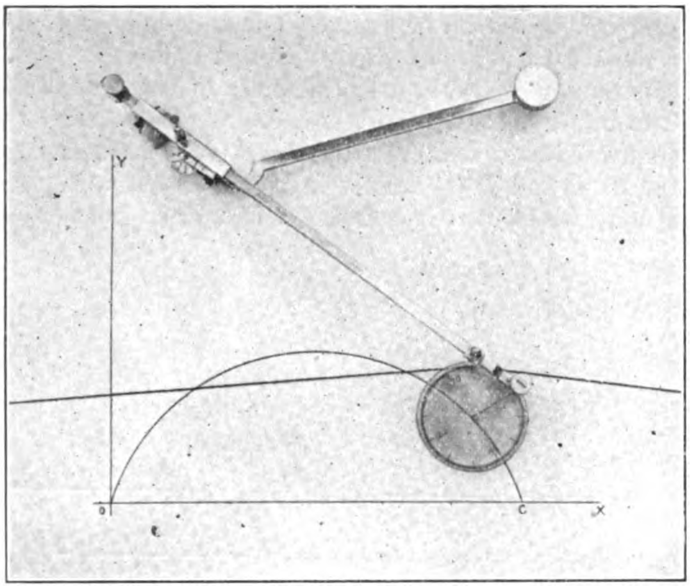

Fig. 2

The disk is now placed with its center at the origin of the curve, and the trough making an angle β with the horizontal axis. If β is zero, a sine component will be obtained; if 90 deg., a cosine component, etc. The planimeter point is placed in depression B, and the planimeter scale set at zero. By placing a sharp point in A, the center of the disk is now made to traverse the path out along the horizontal axis and back along the curve to the origin. To the reading of the planimeter is now added the area under the curve. The result divided by half the length of the base of the curve gives the ordinate of the desired component in terms of the constant of the planimeter. Thus if the planimeter reads in square inches, the final area reading is to be multiplied by two, divided by the base of the curve in inches, and the ordinate will be in inches. This value may then be interpreted in terms of the scale of the curve.

If a complete period of a symmetrical curve is used, the net area under the curve will be zero and the first planimeter reading divided by the half period gives the desired ordinate directly. In other cases the area to be added may be determined by running the planimeter point over the curve in a positive direction.

If several components are desired, they may be determined by separate disks, or all components may be found with the same disk by plotting to different scales. This latter procedure is of course less convenient. A table of disk sizes, scales and order of components is shown in Note 1 for convenience. A rolling planimeter will be found most convenient, although the polar form will do.

The theory of operation is given in appended Note 2. This derivation is not new but is placed here for convenience of those wishing to extend the application of the device to other problems.

The accuracy of the device appears to be limited by the accuracy with which the point may be caused

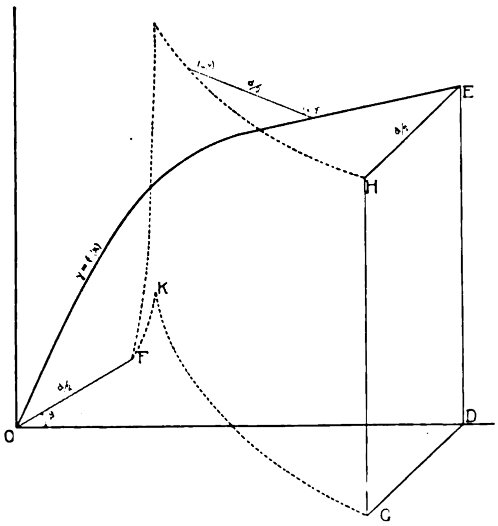

Fig. 3

to trace the curve, that is by the accuracy of the planimeter. Tests on curves of which the components could be formally computed have shown that results obtained may be depended upon to usual planimeter accuracy. The precision is hence greater than that of the oscillograph with which the harmonic analyser is often used, and compares very favorably with that of other mechanical and graphical methods.

In view of the present wide use of the oscillograph and the frequent necessity for curve analysis in other engineering work, it is believed that the above device will be found useful.

NOTE 1.

Table of Order of Harmonics

A set of disks which has been found useful is shown in Fig. 4. There are 20 disks in the set, marked with the length of the base covering one cycle and the

harmonic which will be obtained. Thus 24-1 indicates a disk which will obtain the fundamental when used on a curve plotted so that one cycle is 24 inches in length. The following table indicates harmonics which can be obtained by the use of various ones of these disks. Other combinations are easily obtained.

LENGTH OF ONE CYCLE

Harmonic	48	36	32	24	16	12	8
							24-3
1				24-1	16-1	12-1	8-1
2	24-1		16-1	12-1	8-1		
3	16-1	12-1		24-3	16-3	12-3	8-3
4	12-1		8-1

23							
24							
25							
26	24-13		16-13				
27	16-9	12-9					

NOTE 2.

Theory of Operation

The amplitude of the nth harmonic of a periodic curve $y = f(x)$ is given by:

$$\frac{1}{c}\int_{-c}^{c} f(x)\sin\left(\frac{\pi n x}{c} + \beta\right) d x$$

where $2c$ is the period.

Abbreviating by:

$$\omega = \frac{\pi n}{c}$$

the integral

$$\int f(x)\sin(\omega x + \beta)\, d x$$

is to be evaluated and divided by c in order to give the ordinate of the nth harmonic, where β is the phase angle of the desired component.

Referring to Fig. 3, when the center of the disk traces the path $O\,D\,E\,O$, the planimeter point will trace the path $F\,K\,G\,H\,F$. When the center is at (x, y), the planimeter point will be at (u, v) where

$$u = x + \frac{d}{2}\cos\left(\frac{2x}{d} + \beta\right)$$

$$v = y + \frac{d}{2}\sin\left(\frac{2x}{d} + \beta\right)$$

The area swept out by the planimeter will be:

$$\int v\, d u$$

taken over the boundary $F\,K\,G\,H\,F$.

Along the path $F\,K\,G$ we have $y = 0$ and the total area is hence:

$$A = \int\left[\frac{d}{2}\sin\left(\frac{2x}{d} + \beta\right)\left\{d x - \sin\left(\frac{2x}{d} + \beta\right) d x\right\}\right] - \int\left\{y + \frac{d}{2}\sin\left(\frac{2x}{d} + \beta\right)\right\}\left\{d x - \sin\left(\frac{2x}{d} + \beta\right) d x\right\}$$

or:

$$A = -\int y\, d x + \int y \sin\left(\frac{2x}{d} + \beta\right) d x$$

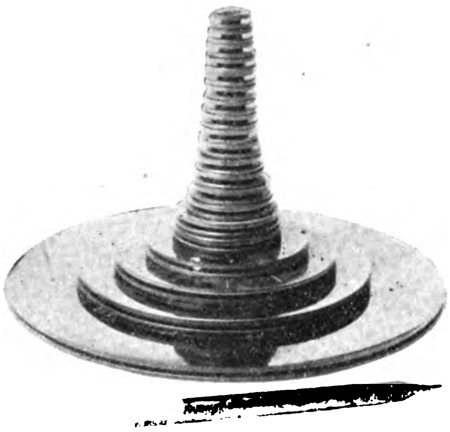

Fig. 4

This will be the value of the planimeter reading.

If we add to this the area under the curve, and set

$$\frac{2}{d} = \omega$$

our result will be:

$$\int y\sin(\omega x + \beta)\, d x$$

or the desired integral.

Thus if the diameter of the disk is chosen with respect to the period of the curve $2c$, in such a manner that

$$\pi d = \frac{2c}{n},$$

the planimeter reading plus the curve area divided by c will give the ordinate of the nth harmonic.

Induction Motor Core Losses*

BY P. L. ALGER

General Electric Co., Schenectady, N. Y.

AND

R. EKSERGIAN

Baldwin Locomotive Works, Philadelphia

An analysis of the core losses in induction motors is the object of the research described in this paper. The authors subdivide the core losses into six elements and point out that only one of the six is ordinarily calculated by designing engineers, with resulting large discrepancies between expectation and fact. The belief is expressed that to calculate other elements approximately is entirely feasible and that such calculations would explain most of the variations in core loss now attributed to imperfections in manufacture.

Rational formulas are developed for the losses in the core back of the teeth, which are found to give larger values than the more approximate formulas now in use, and the conclusions are presented in the form of charts giving the correction factors to apply to the usual formulas for all ordinary conditions.

A Webb floating dynamometer, which was constructed for the measurement of the extremely small torques due to these core losses, is described: and results on the losses in a smooth-core rotor obtained with it are presented. These results and those obtained by an independent electrical method of testing are compared with the expected values based on the theoretical conclusions previously derived, reasonable agreement being found.

Introduction

THIS paper describes certain results of a research directed to improving the precision of computing iron losses in induction motors. The research was carried on by Mr. A. A. Prior and by the authors for the period of a year each during 1914-1917, under the direction of Prof. C. A. Adams, and with the aid of a research appropriation from the American Telephone & Telegraph Co., under the then existing joint cooperative arrangement of Harvard University and the Massachusetts Institute of Technology. The experiments were carried on in the laboratories of both these institutions. After two years of interruption, due to the War, the analysis and collation of the results have been taken up by the authors during the fall of 1919.

It is now the practise of designers to base their estimates of the core losses in projected machines upon previous experience with similar machines, using as criteria of similarity the frequency, the flux densities in core and teeth, and a few general features of design. Actually, the core losses depend upon many of the elements of design. Large discrepancies between the estimated and observed iron losses of new machines are therefore of frequent occurrence, and an entire re-design is sometimes necessitated.

An improved knowledge of the nature and causes of iron losses is evidently very desirable. The ability to predict the core loss more accurately will enable factors of safety in design to be reduced, materials to be more economically utilized, and an intelligent choice between possible alternatives to be made. Until the phenomena of core losses are thoroughly understood it cannot be said that radical reductions may not be made in the losses at present tolerated.

Even if it were true, as is often thought, that the core losses in similar machines varied widely due to slight accidental variations in manufacture, an understanding of the nature and causes of the loss would be exceedingly desirable; since an accidental occurrence is essentially avoidable and such a knowledge would lead to the prevention of the avoidable causes of loss. A careful comparative test recently made of six motors of each of two types shows, however, that the core losses in similar motors made in large scale production do not differ greatly. More than usual care was taken in assembling these motors, and accidental variations were avoided, and the test results must be considered as indicative of better than average conditions. The core losses of the two groups were determined to be as follows:

WATTS CORE LOSS AT 60 CYCLES.

	Group 1.			Group 2.		
	Max.	Min.	Av.	Max.	Min.	Av.
At 250 Volts	340	300	319	335	270	317
At 350 Volts	570	505	550	565	515	544
At 440 Volts	905	820	871	870	790	837
At 550 Volts	1375	1280	1332	1340	1175	1275

These tests give a mean variation of only 3 per cent in core loss between supposedly identical motors.

The problem of predetermination of core losses is of long recognized importance, but as yet the consensus of published opinion is in favor of entirely empirical methods in its treatment. This research was inspired by the belief that a rational and comprehensive investigation of the problem must give the ability to predict with reasonable accuracy the iron losses in any machine.

To be presented at the Pittsburgh Section Meeting, October 12, 1920.

*The continuation on a more comprehensive scale of the research, the early stages of which are discussed in this paper, will be conducted under the auspices of the Division of Engineering of the National Research Council and under the direction of a committee of which Dr. A. E. Kennelly is chairman. One branch of this research is now under way at the Electrical Engineering Laboratory of the Harvard Engineering School.

The method of research outlined was to divide the recognized causes of core loss into reasonably distinct elements which are capable of independent variation and to carry out a series of quantitative tests in which each element was varied over as wide a range as possible. In this way a separation of the elements may be experimentally performed, and comparing the observed character of each loss with expectations based on the theoretical grounds should enable a rational formula to be developed for each element.

For the purposes of study, the iron losses occurring in polyphase induction machines may be analyzed into the following elements:

1. Legitimate losses due to fundamental flux wave.
   a. In the cores.
   b. In the teeth.
2. Fundamental frequency losses due to the leakage fluxes.
   a. Slot leakage flux losses.
   b. Losses in metal wedges.
3. Tooth frequency losses due to permeance variations in the main magnetic circuit.
   a. In the teeth.
   b. In the cores.
4. Tooth frequency losses due to leakage fluxes.
   a. Tooth tip or zigzag flux losses.
5. Pole face or wave losses in the tooth tips.
6. Losses due to nonsinusoidal current distribution.
   a. Losses due to spreading of the main flux in the cores just back of the teeth.
   b. Losses due to harmonics other than tooth harmonics.
7. Illegitimate core losses due to imperfections of manufacture.

Each type of loss occurs in both rotor and stator. Each element may be subdivided into a hysteresis and an eddy current portion; 1 and 3 may be expected to decrease slightly when the machine is put under load, while the others may be expected to increase under load. The latter elements therefore are possible sources of load losses. In addition to these true iron losses there are usually copper losses of appreciable amount which are included in the core loss as ordinarily measured.

These copper losses may arise from the short-circuiting in the rotor of voltages induced by the tooth frequency flux pulsations. Squirrel-cage motors are particularly likely to have losses of this kind owing to the low-resistance paths offered to circulating currents. Another important source of copper losses which are often assumed as core losses exists in the belt leakage fluxes or winding harmonics, which also induce high-frequency circulating currents in the rotor. A third type of extra copper loss is the eddy loss in the copper produced by the slot leakage fluxes. All these types of loss increase with load and form important sources of load loss.

This research is limited to a study of the legitimate no-load core losses. The illegitimate losses of type 7, and the load losses form separate fields of investigation which will not be further touched upon here. It should be emphasized, however, that such losses as these of the types described in the preceding paragraph, which are perfectly subject to predetermination, and yet which are usually neglected, probably form an important source of those discrepancies between expectation and fact that have kept the subject on an empirical basis for so long.

In choosing the element of the true core loss to be first investigated, the qualities of independent existence and fundamental character were sought. The losses of type 1 a, which occur in the core back of the teeth, were consequently selected as the most suitable for first investigation. The results of a study of this element of the loss form the principal subject of this paper. In the next few pages are given the theoretical results obtained and in the succeeding pages the experimental work is described and its results presented.

Iron Losses in the Core Proper

The distributed winding of a polyphase induction motor gives rise to a revolving train of flux waves which are in the usual analysis resolved into a fundamental sinusoidal train and a series of harmonic trains. The fundamental train revolves at a speed equal to $\frac{60 f}{P}$ revolutions per minute, where f is the frequency in cycles per second, and P is the number of pairs of poles. The nth harmonic has $2\,n\,P$ poles and revolves at one-nth the fundamental speed. If the winding were uniformly distributed and had an infinite number of phases, these harmonics would not exist. In practise they are usually small and may be treated independently of the fundamental. They cause losses of type 6 *b*.

The fundamental flux may then be considered as crossing the air gap in a radial direction at every point and as sinusoidally distributed in the gap both as regards time and space. A similar distribution may be assumed to exist at the gap periphery of the stator and rotor cores, if the alternate contractions and rarefactions due to the teeth, which cause losses of type 6 *a*, are neglected.

Rudenberg[1] has obtained expressions for the flux density at any point inside the core for this type of peripheral flux distribution, and his equations will therefore enable the core losses to be computed.

Let:	P	= No. of pairs of poles.	numeric
	θ	= Mechanical angular displacement of any point in core from the center line of a South Pole.	radians
	R	= Radius to any point in core.	cm.

1. *Elektrotechnische Zeitschrift*, 1906-p. 109.

R_a	=	Radius to periphery of core nearest air gap.	cm.
R_i	=	Radius to periphery of core furthest from air gap.	cm.
a	=	$R_a \div R_i$ ($a < 1$ for stator, $a > 1$ for rotor).	numeric
B_r	=	Radial component of flux density at any point in core.	gausses
B_θ	=	Tangential component of flux density at any point in core.	gausses
ϕ	=	Total flux per pole.	maxwells
L	=	Net core length.	cm.

Referring to Fig. 1, and considering an element of area $R\,d\,R\,d\,\theta$ at R, θ, we will apply the two fundamental laws of magnetic distribution. First, *the lines of induction are continuous*, or the total flux entering any area is equal to that leaving it. Expressed as an equation:

$$\frac{d\,B_\theta}{d\,\theta} + B_r + R\frac{d\,B_r}{d\,R} = 0 \tag{1}$$

(1) is true regardless of permeability variations.

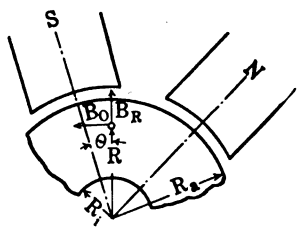

FIG. 1

Second, *the line integral of the m. m. f. around the area is zero*, since there are no currents flowing through the area in a direction perpendicular to its plane. Or,

$$\int H\,d\,l = \int \frac{B}{\mu}\,d\,l = 0$$

To make use of this equation, we will have to take the permeability to be constant (to avoid extreme mathematical complexity), when it becomes:

$$\int B\,d\,l = \frac{d\,B_r}{d\,\theta} - R\frac{d\,B_\theta}{d\,R} - B_\theta = 0 \tag{2}$$

Combining (1) and (2);

$$\frac{1}{R^2}\;\frac{d^2\,B}{d\,\theta^2} + \frac{d^2\,B}{d\,R^2} + \frac{3}{R}\;\frac{d\,B}{d\,R} + \frac{B}{R^2} = 0 \tag{3}$$

(3) is valid for both B_θ and B_r. Its general solution is:

$$B = (A\,R^{\alpha-1} + B\,R^{-\alpha-1})\sin\alpha\,(\theta - \theta_0) \tag{4}$$

To determine the constants, we have the boundary conditions:

When $R = R_a$;

$$B_r = \frac{R\,\phi}{2\,L\,R_a}\cos P\,\theta \tag{5}$$

and when $R = R_i$;

$$B_r = 0 \tag{6}$$

Substituting (5) and (6) in (4), (2), and (1), Rudenberg obtained:

$$B_r = \frac{P\,\phi}{2\,R\,L}\,(A\,R^P - B\,R^{-P})\cos P\,\theta$$

$$= \text{radial density} \tag{7}$$

$$B_\theta = \frac{P\,\phi}{2\,R\,L}\,(A\,R^P + B\,R^{-P})\sin P\,\theta$$

$$= \text{tangential density} \tag{8}$$

Where:

$$A = \frac{R_a^{P}}{R_a^{2P} - R_i^{2P}} = \frac{a^{2P}\,R_a^{-P}}{a^{2P} - 1} \tag{9}$$

$$B = \frac{R_a^{-P}}{R_i^{-2P} - R_a^{-2P}} = \frac{R_a^{P}}{a^{2P} - 1} \tag{10}$$

Equations (7), (8), (9), and (10) completely determine the flux distribution in the core. They apply equally well to the stator or the rotor, the value of a being less than 1 in the first case and greater than 1 in the latter case. The equations show that the flux vector at each point of the core describes an elliptical cycle. The resultant density at any point does not reach zero at any time during a cycle, except where $R = R_i$. Since the permeability depends on the resultant density, and not on B_r or B_θ alone, it is more nearly constant than if the flux were of an alternating character and passed through zero on every cycle. Consequently, the assumption of constant permeability is not so great a source of error as might at first appear.

The eddy current losses due to the radial and tangential flux variations may be calculated independently, since they are always mutually perpendicular in space and can have no interaction on each other. In other words, the eddy current loss due to an elliptic flux variation is equal to the sum of the losses that would be caused by independently acting fluxes of amplitudes equal respectively to the major and minor axes of the ellipse.

Let:

E	=	Normal eddy current loss in core iron at 50 cycles, 10,000 gausses maximum in watts per cu. cm., as determined by Epstein tests.
f	=	Frequency of flux variation in core, or:
$2\,\pi\,f\,t$	= $P\,\theta$ =	Angular distance of revolution in electrical radians, in t seconds.

Then the average eddy current loss occurring at any particular point of the core is:

$$W_1 = E\left(\frac{f}{50}\right)^2 (B_r^2\text{ max.} + B_\theta^2\text{ max.})\,10^{-8}$$

$$\text{watts per cu. cm.} \tag{11}$$

Substituting the values of B_r and B_θ max. from (7) and (8),

$$W_1 = 2\,E\left(\frac{f\,P\,\phi}{R\,L}\right)^2 (A^2 R^{2P} + B^2 R^{-2P})\,10^{-12} \quad \textbf{(12)}$$

The average eddy loss is independent of θ, because of the core's circular symmetry. By integrating (12) over the entire core the total eddy current loss will be obtained:

$$W = L \int_0^{2\pi} d\,\theta \int_{R_i}^{R_a} W_1\,R\,d\,R \quad \textbf{(13)}$$

The limits R_i and R_a should be interchanged when $R_i > R_a$, in the case of the stator core, or the negative sign that will otherwise be obtained should be dropped. Evaluating (13) by means of (12), there is found:

$$W = \frac{2\,\pi\,E\,P}{L}\,(f\,\phi)^2 \left(\frac{R_a^{2P} + R_i^{2P}}{R_a^{2P} - R_i^{2P}}\right) 10^{-12} \text{ watts} \quad \textbf{(14)}$$

Expressed in terms of the ratio of R_a to R_i, a, (14) becomes:

$$W = \frac{2\,\pi\,P\,E\,f^2}{L}\left(\frac{\phi}{10^6}\right)^2 \left(\frac{a^{2P}+1}{a^{2P}-1}\right) \text{watts} \quad \textbf{(15)}$$

or,

$$W = \frac{2\,\pi\,P\,E\,f^2}{L}\left(\frac{\phi}{10^6}\right)^2 \coth\,(P \log_e a) \text{ watts} \quad \textbf{(16)}$$

Equations (14), (15), and (16) express the total eddy current loss in an annular core of uniform permeability subjected to a radial sinusoidally distributed magnetomotive force upon its inner periphery ($a < 1$), or its outer periphery ($a > 1$).

The commonly used formula for this loss is derived by considering only the eddy loss due to the tangential flux, and assuming this flux to be uniformly distributed across the core depth. It is:

$$W' = \text{Volume} \times (\text{Flux Density})^2 \times \left(\frac{\text{Frequency}}{50}\right)^2 \times 10^{-8} \times E.$$

$$= [\pi\,(R_a^2 - R_i^2)\,L]\left[\frac{\phi}{2\,L\,(R_a - R_i)}\right]^2 \left(\frac{f}{50}\right)^2 E 10^{-8}$$

$$= \frac{\pi\,E\,f^2}{L}\left(\frac{\phi}{10^6}\right)^2 \left(\frac{a+1}{a-1}\right) \quad \textbf{(17)}$$

Hence, the usual formula, (17), gives lower values than the new formula, (16). The ratio of (16) to (17) is:

$$K_1 = \frac{W}{W'} = 2\,P\left(\frac{a-1}{a+1}\right)\left(\frac{a^{2P}+1}{a^{2P}-1}\right) \text{ numeric} \quad \textbf{(18)}$$

$$= 2\,P \tanh\,(1/2 \log_e a) \coth\,(P \log_e a)$$

K_1 is equal to 1 when $a = 1$, or for very shallow cores. Its values for different values of P and a are plotted in Fig. 2. For excessively deep cores it approaches the value $2\,P$.

A theoretical value for the total hysteresis loss in the core may be derived in a similar way. In this case, however, the effects of the two perpendicular components of the flux variation are not independent. In fact, the generally accepted hypothesis is that the hysteresis loss due to an elliptic flux variation is the same as that caused by an alternating field of amplitude equal to the major axis of the ellipse. This hypothesis is based on molecular considerations. It will be accepted here.

To simplify the process of integration over the core, the additional assumption will be made that the hysteresis loss varies as the square of the maximum flux density. The 1.6 power law is more accurate, at least for medium densities, but no exponential law fits all cases and the exponent 2 is sufficiently near the average value to be acceptable for the purposes of this paper.

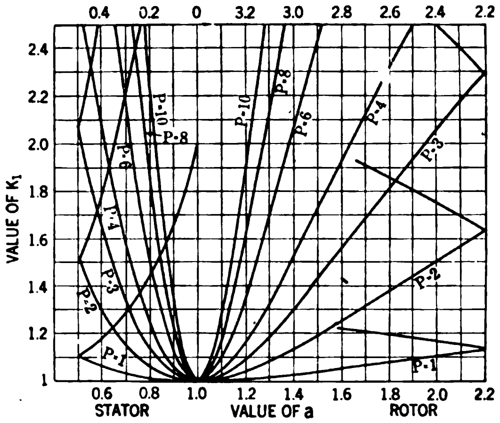

Fig. 2

On this basis, and since the major axis of the elliptic flux variation in the core is always tangentially directed, the specific hysteresis loss at any point of the core is:

$$V_1 = H\left(\frac{f}{50}\right)\left(\frac{B_\theta\,max.}{10^4}\right)^2 \text{watts per cu. cm., } \textbf{(19)}$$

where H is the hysteresis loss in watts per cu. cm. at 10,000 gausses, maximum, and 50 cycles, as determined by Epstein tests on samples of the core iron. B is given by (8).

Integrating (19) over the entire core,

$$V = \left(\frac{H\,f}{50\,L}\right) 10^{-8} \int_0^{2\pi} d\,\theta \int_{R_i}^{R_a} \frac{P^2\,\phi^2\,(A\,R^P + B\,R^{-P})^2}{4\,R}\,d\,R$$

$$= \frac{\pi\,H\,f\,P\,\phi^2\,10^{-10}}{2\,L}\left[\frac{a^P + a^{-P}}{a^P - a^{-P}} + \frac{4\,P}{(a^P - a^{-P})^2}\log_e a\right] \quad \textbf{(20)}$$

(20) may also be expressed as:—

$$V = \frac{\pi\,H\,f\,P\,\phi^2\,10^{-10}}{2\,L}\,[\coth\,(P \log_e a) + P \log_e a \operatorname{csch}^2 (P \log_e a)\,]$$

On the basis of the square law, the usual formula for hysteresis loss, which assumes uniform tangential flux density, is:

$$V' = \frac{\pi H f \phi^2 10^{-10}}{2L}\left(\frac{a+1}{a-1}\right) \tag{21}$$

$$= \frac{\pi H f \phi^2 10^{-10}}{2L} \coth\,(1/2 \log_e a)$$

Hence the ratio of the hysteresis loss with uniform permeability to that with uniform tangential flux distribution is:

$$K_2 = \frac{V}{V'} = P\left(\frac{a-1}{a+1}\right)$$

$$\left[\frac{a^P + a^{-P}}{a^P - a^{-P}} + \frac{4P}{(a^P - a^{-P})^2}\log_e a\right] \quad \text{numeric} \tag{22}$$

$$= P \tanh\,(1/2 \log_e a)\,[\coth\,(P \log_e a) + P \log_e a \operatorname{csch}^2 (P \log_e a)\,]$$

K_2 is plotted as a function of a and P in Fig. 3. Its value approaches unity for very shallow cores, while for very deep cores it apprcaches the limit P.

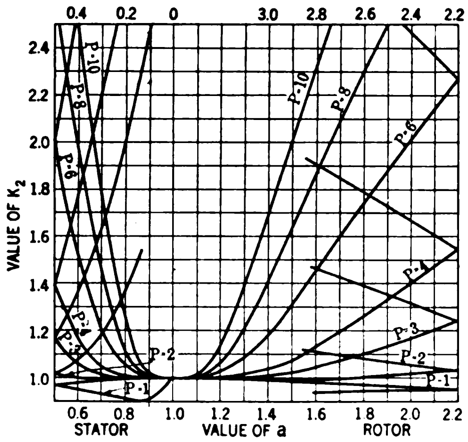

FIG. 3

In the case of a deep rotor core of uniform permeability and a small number of poles, the flux takes a nearly straight path from pole to pole, and hence the increased specific loss caused by the non-uniform distribution of flux is more than offset by the fact that the higher densities occur in the inner half of the core, and hence in a smaller volume of iron. This explains the existence of values of K_2 below 1.

Another interesting ratio which may be derived from these equations is the ratio of the m.m.fs. required to force the flux through the core under the two assumptions of uniform permeability and uniform tangential density. The core ampere turns per pole are equal to $1/2 \int H\,d\,l$ along any path between two adjacent pole centers. Choosing, for convenience, the path along the core periphery nearest the air gap, we have from (**8**), (**9**), and (**10**), when $R = R_a$:

$$B_\theta = \frac{P\phi}{2 L R_a}\left(\frac{a^P + a^{-P}}{a^P - a^{-P}}\right)\sin P\,\theta \tag{23}$$

Since B_θ varies sinusoidally with θ, its average value over the half pole pitch is $\frac{2}{\pi}$ times its maximum value. The length of path is $\frac{\pi R_a}{2P}$, so that the ampere turns per pole are:

$$N\,i = \int \frac{B}{\mu}\,d\,l$$

$$= \frac{P\phi}{2\mu L R_a}\left(\frac{a^P + a^{-P}}{a^P - a^{-P}}\right)\left(\frac{2}{\pi}\right)\left(\frac{\pi R_a}{2P}\right)$$

$$= \frac{\phi}{2\mu L}\left(\frac{a^P + a^{-P}}{a^P - a^{-P}}\right)$$

$$= \frac{\phi}{2\mu L}\coth\,(P \log_e a) \tag{24}$$

The usual formula, based on the assumption of a uniformly distributed flux across the core depth, is:

$$N\,i' = \frac{2}{\pi}\left(\frac{\text{max. flux density}}{\mu}\right)(1/2 \text{ mean pole pitch})$$

$$= \frac{2}{\pi\mu}\left(\frac{\phi}{2L(R_a - R_i)}\right)\frac{\pi (R_a + R_i)}{4P}$$

$$= \frac{\phi\,(a+1)}{4\mu P L\,(a-1)}$$

$$= \frac{\phi}{4\mu P L}\coth\,(1/2 \log_e a) \tag{25}$$

Hence the ratio of the constant permeability value to the usually taken value of the core ampere turns is:

$$K_3 = \frac{N\,i}{N\,i'} = \frac{2P\,(a-1)\,(a^P + a^{-P})}{(a+1)\,(a^P - a^{-P})} \quad \text{numeric} \tag{26}$$

$$= 2P \tanh\,(1/2 \log_e a)\coth\,(P \log_e a)$$

Equation (**26**) is identical with (**18**) so that $K_3 = K_1$ and the variations between the two formulas for core ampere turns are the same as those between the two formulas for eddy current loss and both are represented by Fig. 2.

It will be noted that formula (**24**) is exact if the permeability is constant and it therefore furnishes a useful means of computing the external reactance of the stator of an induction motor with rotor removed, or vice versa. In such a case, a equals eithe ,
and (**24**) reduces to the very simple form:

$$Ni = \frac{\phi}{2 \mu L} \text{ ampere turns per pole} \quad (27)$$

(For air, $\mu = \frac{4\pi}{10}$ if L is taken in cm.)

Reviewing the theoretical conclusions reached, formulas (**16**), (**20**), and (**24**), respectively express the total eddy loss, the total hysteresis loss, and the m. m. f. per pole existing in a laminated cylindrical core without teeth and of uniform permeability, when the core is subjected to a radial sinusoidally distributed flux on one of its cylindrical surfaces. The assumption of constant permeability makes the calculated eddy current loss too small as it neglects the extra losses produced by the harmonics which always accompany variations in μ.[2] The assumption makes the hysteresis loss too large, as saturation tends to equalize the density across the core.

Leaving out of consideration the extra losses due to the concentrations of flux behind the teeth, which should be treated separately, the formula for the eddy loss gives too small results and that for the hysteresis too large results.

The Supply of Losses

It is impossible to produce a single element of the core loss in an induction motor without causing the simultaneous existence of a copper loss in the exciting winding, friction and windage losses, and other types of core loss, so that great care must be exercised in considering what losses are actually measured, in any method of core loss determination used experimentally, if the results are to be of value. Before a method of testing is adopted, therefore, it is desirable to make a careful study of the manner in which the power represented by the losses is actually delivered from the electric circuit to the point of its ultimate consumption. The knowledge given by such a study is also indispensable in considering the results of tests.

On account of the importance of this subject the next several paragraphs will be devoted to its consideration.

The electric circuit of the stator and the shaft of the rotor are the only two sources of external power supply or consumption in the case of the normal induction motor. If a motor with an unwound rotor is considered it is evident that the only losses occurring in the rotor are iron losses and that all such losses must be supplied either by an external driving torque applied to the shaft or by a magnetic torque exerted at the air gap due to a current in the stator circuits. With steady running, the algebraic sum of the torques acting on the rotor is zero. Therefore, with friction and windage torque either known or constant, measurement of the external torque applied to the shaft will determine the air gap torque, which is due to the rotor iron losses. On this account it is relatively easy to determine experimentally the rotor iron losses independently of the existence of other losses. This facility of separate measurement, together with the fact that the theories of the rotor and stator iron losses are exactly similar, led to the decision to concentrate the experimental part of the research on the measurement of the rotor iron losses. Even after the air gap torque is known, however, it is not clear how the rotor iron loss is determined, so that a careful analysis of the relationships between speed and torque is necessary.

A rotating field produced by a smooth-core induction machine is equivalent to a revolving field magnet. As a result of hysteresis and eddy currents in the rotor (the rotor current may be considered as an eddy current), a displacement is produced between the stator m. m. f. and the flux, which displacement causes a torque proportional to the sine of the angle of advance. This torque opposes the relative motion of flux and rotor and hence tends to accelerate the latter when below synchronous speed and retard it when above. At exact synchronism there are no eddy currents in the rotor and the air gap torque is entirely due to hysteresis. This hysteresis is analogous to friction in that it produces only so much torque as may be necessary to prevent relative motion of flux and iron, subject to the limitation that it can not exceed a certain limiting value. Accordingly this torque may be either positive, negative, or zero and the rotor flux may either lag, lead, or be in exact phase with the revolving field magnet according to the amount of torque supplied from other sources.

The torque exerted upon the rotor takes from the electrical system power represented by $T_c\, \omega_s$ (where ω_s = synchronous ang. velocity and T_c = total torque due to the rotor losses). In overcoming friction, etc., this torque does mechanical work = $T_c\, \omega$ (where ω = angular velocity of rotor). Hence the power dissipated in the rotor is $T_c\,(\omega_s - \omega)$. Expressing this as an equation:

$$\underbrace{T_c\, \omega_s}_{\text{Power taken from stator and transmitted across air gap.}} = \underbrace{T_c\, \omega}_{\text{Mechanical work}} + \underbrace{T_c\,(\omega_s - \omega)}_{\text{Total loss in rotor}} \quad (\mathbf{28})$$

This equation adequately represents the distribution of the power consumed in the case of a smooth-core rotor revolving in a sinusoidal field, but in this case only. If harmonics exist in the field form which have different synchronous speeds from the fundamental, a similar equation to the above will hold true for each harmonic separately and the complete distribution of power will be represented by the sum of all the separate equations. In the calculation of losses, all harmonics having different frequencies in the rotor may as a first approximation, be treated independently since they can have no interactions except those due to temperature and saturation effects. In general, the rotor speed

2. A. E. Kennelly and P. L. Alger, Proc. A. I. E. E., Vol. XXXVI, Dec. 1917, p. 1113-1131.

ω, will be above the synchronous speed, ω_s, of some harmonics, and below that of others. Hence in some cases, $\omega_s - \omega$ and also T_c will be positive, and in other cases they will be negative or zero. Therefore the method of supply of the power is determined by the signs of the terms of this equation. There are three cases:

I. If $T_c\, \omega_s$ and $\omega\, T_c$ are both positive, all power is supplied by the stator electric circuit. $(0 < \omega < \omega_s)$

II. If $T_c\, \omega_s$ is positive and $\omega\, T_c$ is negative, power is supplied both electrically and mechanically.

$$(\omega < 0,\ \omega_s > 0)$$

III. If $T_c\, \omega_s$ and $\omega\, T_c$ are both negative, all the power is supplied mechanically, as by a driving motor.

$$(\omega > \omega_s)$$

Since the total air gap torque is the algebraic sum of the torques produced by all the harmonics, while the core loss is the sum of the products of the individual harmonic torques by their respective values of slip, $(\omega_s - \omega)$, it is necessary to analyze the observed torque into its components before the core loss can be obtained. It is thus seen that unless a sinusoidal field is used, important errors may result from the hasty conclusion that the total rotor core loss is measured by the product of the observed air gap torque, T_c, and the fundamental slip speed, $\omega_s - \omega$.

To make this more clear, consider the case of a revolving field containing a seventh harmonic revolving in the same direction as the fundamental but having a synchronous speed 1/7 as large, or $\omega_{s7} = 1/7\ \omega_{s1}$. Such a harmonic exists in the field produced by the usual three-phase winding. Then the observed air gap torque is:

$$\Sigma\, T_c = T_{c1} + T_{c7}$$

and the total rotor loss is:

$$\Sigma\, T_c\,(\omega_s - \omega) = T_{c1}\,(\omega_{s1} - \omega) + T_{c7}\left(\frac{\omega_{s1}}{7} - \omega\right),$$

quite different from:

$$(T_{c1} + T_{c7})\,(\omega_{s1} - \omega),$$

which is *apparently* equal to the total rotor loss. The latter expression is less than the former by an amount $6/7\ \omega_{s1}\, T_{c7}$ which represents the difference between the power actually supplied by the electric circuit and that which would have been supplied if all the torque had been delivered at a speed ω_{s1}.

So far, there has been considered only the case of a smooth-core machine, or one in which the air gap permeance does not vary. If this permeance does vary, due to the presence of slots, a further complication enters the energy equations.

It is a general principle that whenever any cyclic variations in the permeance of a magnetic circuit are caused by the relative movement of parts of the circuit, all the losses caused by this variation are supplied by the mechanical agency causing the motion. In the case of an induction motor running alone, this mechanical agency is the torque produced by the rotor current and fundamental core loss.

The proof of this principle for the case of a direct-current electromagnet whose keeper is cyclically moved follows directly from the facts that all the losses due to the motion are manifested in the same way as the pulsating currents induced in the magnet winding, and that these currents draw no power from the supply circuit since the product of an alternating current and a constant voltage gives a net power equal to zero. The proof in the more general case of an alternating-current circuit follows by analogy to the direct-current case, or may readily be proved by an application of Kelvin's law[3] to the power equation of the circuit.

In general, there are teeth on both sides of the air gap, and so pulsation losses due to permeance variations occur in both stator and rotor. All the pulsation losses are supplied by a mechanical torque just as friction is supplied, so that in the case of a normal motor a rotor current must flow which is large enough to supply a torque that together with the fundamental core loss torque, will overcome both pulsation and friction losses, while in the case of a motor with unwound rotor the fundamental core loss torque plus the externally applied driving torque must be large enough to overcome both these losses.

Calling T_p the torque necessary to supply all the pulsation losses in both stator and rotor, and T the accelerating torque supplied by a driving motor, we obtain for the correct loss equation:—

$$\underbrace{\Sigma\, T_c \omega_s + T_\omega}_{\text{Power from stator + power from driving motor}} = \underbrace{T_{f+\omega}\,\omega}_{\text{Friction and windage loss}} + \underbrace{T_p\,\omega}_{\text{Total pulsation loss}} + \underbrace{\Sigma\, T_c\,(\omega_s - \omega)}_{\text{Rotor core losses proper}} \qquad (29)$$

$$\text{or}\quad \Sigma\, T_c + T = T_{f+\omega} + T_p \qquad (30)$$

If the excitation is removed and ω is preserved constant, the applied torque, T, will increase until it equals the friction and windage torque. Hence the increase in the driving torque as the stator excitation is thrown off is equal to

$$\Delta\, T = \Sigma\, T_c - T_p \qquad (31)$$

From this discussion we may conclude that if ΔT, the change in the torque applied to the shaft of an induction motor as the excitation is thrown on or off, the motor speed being preserved constant, is measured by some form of dynamometer, this change in torque is a measure of the rotor core loss, subject to the following restrictions:

(a) If both rotor and stator have smooth cores so that no permeance variations occur, and if the stator m. m. f. is sinusoidally distributed around the periphery at every instant, then the product of $\Delta\, T$ and the slip, $\omega_s - \omega$, in watts, is exactly equal to the total core and copper losses occurring in the rotor.

(b) If there are no permeance variations, but the stator m. m. f. contains space harmonics which re-

3. Karapetoff, "The Magnetic Circuit," page 253.

volve at different synchronous speeds from the fundamental, ΔT is the algebraic sum of the torques due to the several harmonics, to each of which relation (a) applies separately. Before the total rotor loss can be known, ΔT must be analyzed into its parts, as each harmonic has a different value of slip.

(c) If permeance variations exist as a result of the rotation, ΔT is equal to the difference between ΣT_c and T_p, where $T_p \omega$ in watts is equal to the total pulsation loss occurring in both rotor and stator and $\Sigma T_c (\omega_s - \omega)$ is the total remaining rotor loss. Hence here also ΔT must be analyzed into its elements before any of the losses can be determined.

It is on the basis of these principles that measurements of rotor core loss were made in this research. That is, the change in the driving torque, ΔT, due to the stator excitation, was measured directly with dynamometer. There is, however, another convenient method of measurement of the rotor core loss which was used as an independent check. This latter method consists in the comparison of the total input to the electric circuit of the stator when the motor is running light with the input with rotor stationary. It will hereafter be referred to as the electrical method in contradistinction to the dynamometer method previously discussed.

The general energy equation reduces to (**28**) when no harmonics and no permeance variations exist. In this equation, T_c, representing the torque due to the total rotor losses, may be divided into two components due, respectively, to the hysteresis and the eddy current losses:

$$T_c = T_h + T_e \tag{32}$$

T_h, the hysteresis torque, is proportional to the hysteresis loss *per cycle*, so that it is independent of the frequency. T_e, the eddy current torque, is proportional to frequency, except at such high frequencies that damping and leakage reactance effects become appreciable. The frequency in the rotor is proportional to $\omega_s - \omega$, so that (**32**) may be expressed as:

$$T_c = T_h + E\,(\omega_s - \omega) \tag{33}$$

Substituting (**33**) in (**28**) there is obtained:

$$\underbrace{T_c\,\omega_s}_{\text{Output of stator to rotor}} = \underbrace{T_c\,\omega}_{\text{Mechanical work}} + \underbrace{T_h\,(\omega_s - \omega)}_{\text{Hysteresis loss}} + \underbrace{E\,(\omega_s - \omega)^2}_{\text{Eddy current loss}} \tag{34}$$

Suppose that the stator is excited with sinusoidal alternating current, the unwound rotor is driven by an external torque, and the electrical input to the stator is measured with wattmeters. When the rotor speed is below synchronism, or $0 < \omega < \omega_s$, the power input to the stator is:

$$\begin{aligned} P_s &= \text{Stator losses} + (T_h + T_e)\,\omega_s \\ &= C_1 + E\,\omega_s\,(\omega_s - \omega) \end{aligned} \tag{35}$$

That is to say, the hysteresis torque and the stator losses remain constant as the speed increases while the eddy current torque decreases linearly to zero as synchronism is approached.

At synchronism, the eddy current torque is zero, and the hysteresis torque may be either positive, negative or zero, just as the force of friction may have any value between limits before relative motion commences. Above synchronism, or when $\omega > \omega_s$, both T_h and T_e are negative, and the power input to the stator is:

$$\begin{aligned} P_s &= \text{Stator Losses} - (T_h + T_e)\,\omega_s \\ &= (C_1 - 2\,T_h\,\omega_s) - E\,\omega_s\,(\omega - \omega_s) \end{aligned} \tag{36}$$

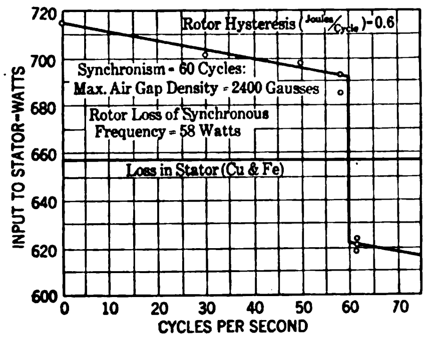

Fig. 4—Input to Stator With Rotor Rotating at Different Speeds

It follows from (**35**) and (**36**) that the difference between the stator electrical input at a speed just below synchronism and that at a speed just above synchronism is equal to $2\,T_h\,\omega_s$, or twice the hysteresis loss occurring in the rotor at line frequency. It also follows that the difference between the electrical inputs at zero speed and at a speed just below synchronism is equal to $E\,\omega_s^2$, or the total eddy loss in the rotor at line frequency.

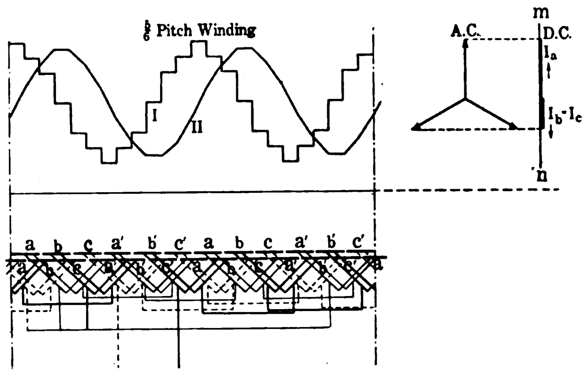

Fig. 5—Winding or Belt Diagram—5/6 Pitch
I. Current Distribution.
II. M. M. F Distribution.

The determination of the rotor losses by this process constitutes the electrical method of test. An experimental curve of stator input against rotor speed is shown in Fig. 4.

Experimental Work

In the preceding pages there have been described in turn the general object of the investigation, the theory of the first element of core loss to be investigated, and the theory of the testing methods employed. It remains to describe the experimental work performed.

A set of several interchangeable rotors and stators of 7-in. gap diameter with different numbers of teeth and different windings was collected for this research. The experiments to be described, which had as their object the determination of the losses due to the fundamental flux in a smooth-core rotor, were carried out with a smooth-core, Gramme ring-wound, three-phase two-pole stator and a smooth rotor without winding. The design data on this motor were as follows:

DESIGN DATA FOR SMOOTH-CORE SET.

Stator		Rotor	
Winding:	three-phase, two-pole ring-wound double-layer, 5/6-pitch.	Winding:	None
		No. of slots:	None
		Speed:	3600 Rev. per min.
Total conductors:	504, No. 20 B & S.	Peripheral Velocity:	110 ft. per sec.
No. of slots:	None	Gap Diameter:	6.81 in.
Frequency:	60 cycles.	Core length:	4.40 in.

Core length:	4.38 in.	No. of 0.034-in. "	7
		Material:	Best silicon steel laminations and brass spider.

Driving Motor: one-h. p., 115-volt d-c., rated 1800 rev. per min.
Magneto for speed measurements: Ball bearing type giving 10 volts at 1000 rev. per min.
Alternator for Power supply: three-phase, 15-kv-a. 20-70- cycle especially designed to give a pure sine wave e. m. f.

It was desired to produce in this rotor a perfectly sinusoidal flux distribution and to measure the resulting losses at various frequencies and flux densities. The sinusoidal character of the field was ensured by using as a source of power an alternator which had an e. m. f. containing no harmonics greater than 1 per cent of the fundamental and by disposing the stator winding in such a way as to secure a sinusoidal space distribution of m. m. f. Actually it was calculated that the 5/6-pitch ring winding used produced fifth and seventh space harmonics of m. m. f. of magnitude respectively 1.0 and 0.5 per cent of the fundamental. These figures are negligibly small, so that it is considered that the wave form of the flux actually produced in the air gap was satisfactorily near a sine wave. This belief was confirmed by oscillographic measurements of the flux with an exploring coil on the rotor.

Extra losses in the rotor were guarded against by the use of seven-mil paper insulation between laminations, and the provision of a brass spider. Extra losses in the stator were of no importance, since only the rotor core loss was measured. The very long air gap required by the use of a ring-wound stator made extra losses due to possible eccentricity of the rotor negligible. Care was taken to place the rotor centrally in the stator.

The test machines having been provided, it only remained to develop a suitable apparatus for the measurement of the losses. Four methods of core loss measurement were tried. The first method was to drive the rotor by a small direct-connected d-c. motor and to obtain the losses as the motor input less its output. This was unsatisfactory on account of the magnitude and variability of the losses in the d-c. motor. The second method was to measure the driving torque of the d-c. motor by means of a torsion spring dynamometer. This was very unsatisfactory on account of lack of sensitivity and the occurrence of severe vibrations at the high speeds used. The third, and most successful, method was to measure the core loss torque directly by means of a Webb floating dynamometer. The fourth method was the electrical

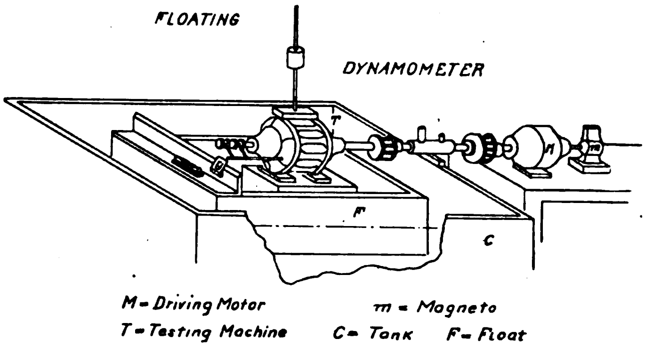

Fig. 6

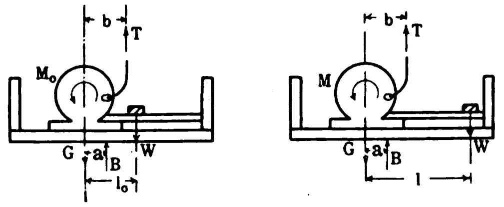
method, previously described. Another method that could have been used, and which Bragstad[4] has used successfully for a like purpose, is that of determining the retardation of the rotor as it slows down when the driving torque is removed.

Since the total losses in this rotor varied between 5 and 100 watts under the conditions of test, their determination involved the measurement of a torque of the order of magnitude of 10^6 dyne ⊥ cm. (0.074 lb. ⊥ ft.). To obtain an accuracy of 5 per cent it is necessary to be able to detect readily a change in torque of about



Without Load With Magnetic Load

Fig. 7

50,000 dyne ⊥ cm., which means that a dynamometer of unusual sensitivity was required. The Webb floating dynamometer has the advantages of great sensitiveness, and of giving a null reading at the start. On account of the novelty and usefulness of this dynamometer, its construction and operation will be described in some detail.

This dynamometer consists essentially of a tank of water in which floats a substantial wooden box supporting the experimental motor. The motor is connected by means of a flexible coupling to the driving motor, which is placed on a stand external to the tank. The float is provided with movable weights, scales and levels enabling it to be adjusted to an exactly level

4. *Elektrotechnishe Zeitchrift*, Nov. 1908, p. 1074.

condition. A perspective view of the apparatus is presented in Fig. 6.

To operate the dynamometer, the driving motor is set in operation and brought up to speed, sufficient time is allowed to elapse for bearing friction and other changing conditions to become constant, and the float is carefully leveled. Any change in the torque transmitted by the driving shaft causes the float to tilt in a plane at right angles to the shaft, and the amount of this change in torque is readily measured by the couple represented by the shift in the weights necessary to restore the float to an even keel. Consequently by throwing the stator excitation on and off and successively relevelling the float, the core loss torque may be measured. Referring to Fig. 7, we have, with excitation off:

$$M_0 + B_a + T\,b - W\,l_0 = 0,$$

and with excitation on:

$$M + B\,a + T\,b - W\,l = 0,$$

whence

$$M - M_0 = W\,(l - l_0).$$

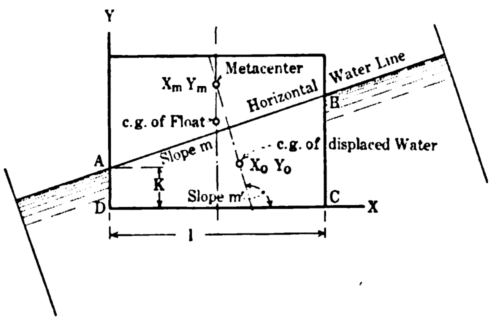


FIG. 8—LOCATION OF METACENTER

Or, the core loss torque is equal to the product of the balancing weight by the change in its lever arm.

The sensitivity of this dynamometer, or the angular tip per unit torque applied, is readily adjusted to any desired value by means of a weight sliding on a vertical pole in the center of the float. Raising this weight raises the center of gravity of the entire float, making it more top heavy, and consequently increases the sensitivity, while lowering the weight has an opposite effect. The measure of the sensitivity is the distance of the center of gravity of the float below the metacenter. The metacenter is the point of intersection of a vertical through the center of gravity of the displaced water with that principal axis of inertia of the float which is vertical at equilibrium. Fig. 8 presents this statement diagrammatically. If the center of gravity is above, at, or below the metacenter, the float will be in unstable, neutral, or stable equilibrium.

An evident objection to making the float very sensitive is the increased time required in coming to rest after a disturbance. The time of one oscillation of the float is approximately proportional to $\dfrac{1}{\sqrt{h}}$ where h is the height of the metacenter above the center of gravity. To secure satisfactory rapidity of operation coupled with high sensitivity the oscillations must be damped by hand. In practise the least change in torque it was found feasible to detect readily was about 40,000 dyne $\perp$ cm. (0.003 lb. $\perp$ ft.) or 1.5 watts at 3600 rev. per min.

Several experimental difficulties were encountered in operating of the dynamometer. In the first place, the end play of the motor shaft in its bearings caused the rotor to shift to and fro during a reading, thus varying the friction and causing errors in the measured torque. The magnetic pull of the field has a tendency to make the rotor position with field on different from that with field off, thus introducing a consistent error. Since the expense of providing ball bearings was prohibitive, this difficulty was met by mooring the float in position in the tank with horizontal elastic bands, which were stretched taut enough to hold the rotor in its position of magnetic equilibrium when the field was off. By reason of their being in a horizontal plane, the forces exerted by these cords did not affect the balance of the float, though they did have a tendency to damp out oscillation.

In the second place, the occurrence of large oscillations when the field was put on and off caused the sides of the float to get wet over an inch or more of free surface, and it was actually found that the inequality in the weight of water adhering to the wetted areas on the two sides of the float (equivalent to a film about 0.02 cm. deep) was sufficient to disturb the balance materially. This difficulty was surmounted by placing buffers to limit the oscillations of the float to a small arc.

A third difficulty lay in the vibrations produced by lack of balance in the rotating parts, which caused the float to execute forced oscillations. To overcome this difficulty it was necessary to carefully balance dynamically all revolving parts, and in fact a very considerable part of the total time spent on this research was devoted to study and experimental work in connection with this question of balance. The problem of balance was as difficult at speeds below 400 rev. per min. as at high speeds on account of the low natural frequency of oscillation of the dynamometer float.

The following data will convey a clear idea of the design of the dynamometer:

DESIGN OF FLOATING DYNAMOMETER.

	Tank	Float
Material	1 3/4-in. pine	1 3/8-in. pine
Construction		Box lined with tin.
Axial length, outside	52 in.	42 in.
Width "	48 in.	36 in.
Depth "	20 3/4 in.	18 in.
Immersed depth		8 in.
Weight of float proper		135 lb.
" " test machine, leads, and weights		320 lb.

In core loss measurement, the accurate determination of the rotor speed is of course an important factor

in the final precision attained. Throughout the experiments the speed was measured by a small magneto and voltmeter which were carefully calibrated at frequent intervals. The importance of knowing the speed accurately lay chiefly in the necessity for preserving precisely the same speed during torque measurments with the stator field on and with it off, in order to prevent the inclusion in the measurements of variations in the frictional torque. The

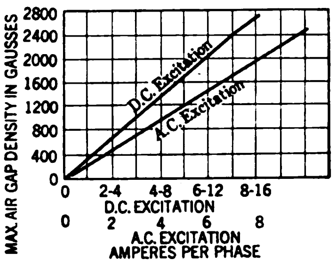

Fig. 9—Saturation Curve—Smooth-Core set

core loss torque itself does not vary rapidly with changes in speed. To secure this desirable constancy of speed, it was found expedient to use a storage battery as the source of power for the driving motor.

To furnish a basis for the calculation of the core loss, it was necessary to determine the gap density corresponding to any value of the stator current. A calibration curve giving the crest value of the sinusoidal flux wave in the air gap as a function of the phase current was obtained by means of an exploring coil of very fine wire encircling the rotor core. The ends of this coil were brought out to slip rings and the voltages induced in it at various speeds and excitations were measured with an electrostatic voltmeter.

By tests, the air gap flux was the same with three-phase alternating current as with an equivalent d-c. excitation of the stator. The final calibration curve is shown in Fig. 9. To secure a sinusoidal flux distribution with d-c. excitation, the current in one phase was adjusted to twice that in the other two, thus simulating the current values at the instant of a three-phase excitation at which the current in one phase is a maximum. The effective a-c. current per phase corresponding to this d-c. excitation is then $\frac{1}{\sqrt{2}}$ times the direct current in the over-excited phase.

Three sets of tests were made on the smooth-core rotor revolving in the smooth-core stator, as previously described, using the floating dynamometer to measure the torque due to the total core loss in the rotor. The first tests were made in the fall of 1915, and the others in the spring of 1916 after the dynamometer had been renovated in consequence of defects in its construction. In the first two tests the rotor was subject to vibration due to unbalance, in the last test it was perfectly balanced. All these tests were in the nature of trials in which the various experimental difficulties were successively encountered and overcome, so that their accuracy is not ideal.

The core loss torque was measured with five different excitations of the stator, using direct current. For each excitation, the torque was measured at several different rotor speeds, so that a chart showing the core loss as a function of speed and flux density was established.

The results obtained by the dynamometer method were calculated as follows:

The weight of the slider used to balance the float was 58.63 grams. Calling L (cm.) the displacement of the slider necessary to rebalance the float when the field was thrown on or off, the core loss torque, T, is:

$$T = 58.63\, L \times 981 = 5.75\, L \times 10^4 \text{ dyne} \perp \text{cm.}$$

and, calling the rotor speed in revolutions per minute N, the core loss is

$$W = \frac{2\,\pi\, N\, T}{60}\, 10^{-7} = 6.01\, L\, N \times 10^{-4} \text{ watts.}$$

The average core loss torque for each setting, in joules per cycle (watt seconds per cycle), is plotted against frequency in Fig. 10. The mean results of the first two sets of tests are indicated by small circles, the results of the third test by double circles. The first tests are believed to have given too high results because of changes in the rotor friction when the field was thrown on and off. The last set of tests is believed to be accurate as the rotor was perfectly balanced and the entire set operated very smoothly during the experiments.

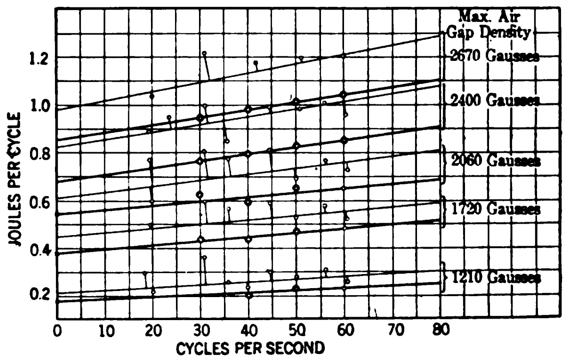

Fig. 10—Core Loss Torque vs. Speed for Smooth Rotor Obtained by Dynamometer.

In drawing the final representative lines on the chart, the earlier data were rejected, and only the final set of readings was taken into account, as shown by the heavy lines in Fig. 10. Further check tests which were planned, were prevented by the removal of the apparatus from Harvard to the new Technology buildings in the summer of 1916, and there has been no later opportunity to repeat them.

To check independently the dynamometer results, tests were also made by the electrical method previously described. The stator was excited with three-phase sinusoidal alternating current and the total

input was measured with wattmeters. The rotor was then driven up to synchronous speed by a driving motor, and the electrical input was measured, when the speed was just below and just above synchronism. In Fig. 4 there are illustrated the results of a test of this nature. The stator input falls linearly with increase in rotor speed until synchronous speed is reached, when it drops sharply, and then resumes its linear fall with further increase in rotor speed.

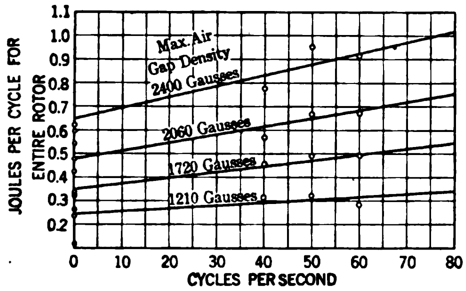

Fig. 11—Core Loss Torque vs. Speed for Smooth Rotor
Obtained by Electrical Method.

The chief objection to this method is that common to all difference methods. The rotor core loss is obtained as the difference of two relatively large quantities (about 10 times as large in this case), and hence can only be accurately determined by averaging a large number of tests. Since it takes an appreciable

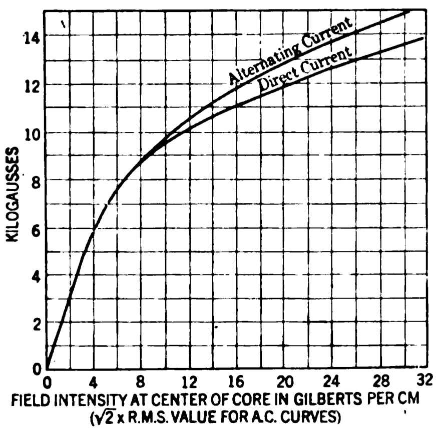

Fig. 12—Saturation Curve of Smooth-Core Rotor
Obtained by Transformer Method.

time for the rotor to come up to speed, changes in temperature of the stator during the interval between readings at zero and synchronous speeds may occur and cause changes in the stator losses, and hence important errors.

Fig. 11 shows the results of tests by this electrical method at four different excitations. The rotor core loss in watt seconds per cycle is plotted against the frequency in the rotor. The ordinates at zero speed were obtained by taking half the break in the stator watts input at synchronism and dividing it by the frequency. The experimental data are very inexact, and representative lines have been drawn without attempting to determine their most probable positions.

These lines agree roughly with the dynamometer results, the chief difference being that they indicate a larger percentage of eddy current loss.

Calculation of Losses

To furnish a basis for calculations of the core loss by the formulas derived in the earlier portions of this paper, the hysteresis and eddy current constants of the rotor core were determined by stationary tests, after the completion of the tests just described. The rotor shaft was removed from the spider and a ring winding

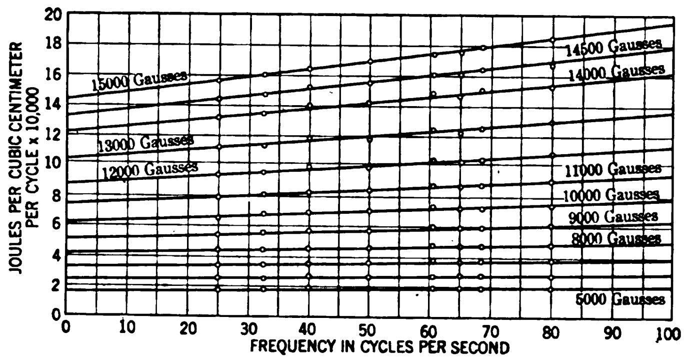

Fig. 13—Core Loss per Cycle vs. Frequency for Complete Smooth-Core Rotor
Determined by Transformer Tests under Sine Wave Voltage.

was placed around the rotor core, the wires passing through the openings between the spider arms. Exciting this winding from a sine wave source of voltage, the rotor core was magnetized with a tangentially directed alternating flux. Saturation curves for both a-c. and d-c. excitation are given in Fig. 12. The iron losses were measured by the wattmeter method with all the usual precautions against error.

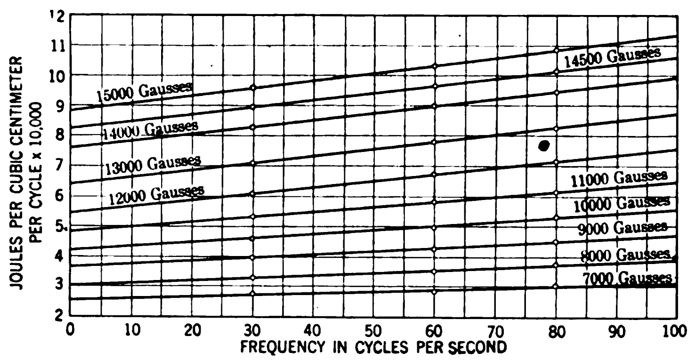

Fig. 14—Core Loss per Cycle vs. Frequency for Smooth-Core Rotor (Spider and End Plates Removed)
Determined by Transformer Tests.

The results of these tests are presented in Fig. 13. The core loss per cycle for constant density was found to be a linear function of the frequency, as expected. The losses thus found however, are considerably larger than (about thrice) the expected losses for this type of steel. To investigate this unexpectedly large loss, the rotor was taken down, the spider and thick end plates removed, and the 14-mil laminations were reassembled separately. Similar core loss measurements on the new core gave losses only about two-thirds as large as before. These results are shown in Fig. 14.

These excessive losses are attributed to the presence of three assembly notches on the inner periphery of the stampings and an extra notch in the outer periphery, all of which caused constrictions in the flux path and consequently increased losses. When the experiments were begun, the presence of the inner notches was not thought of, and the notch in the outer periphery was not considered a source of important extra loss. A scale drawing of one stamping is shown in Fig. 15.

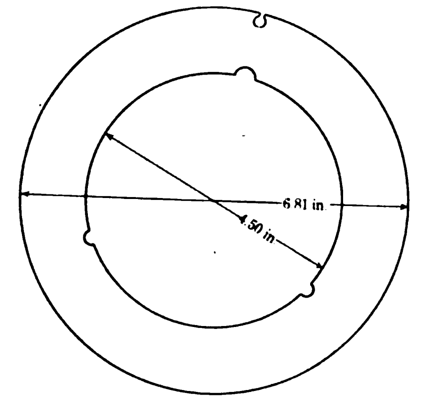

FIG. 15—SAMPLE LAMINATION OF SMOOTH-CORE ROTOR

Evidently the experiments just described uncovered a new source of disagreement between the measured core losses and the calculated ones.

The complete rotor core consisted of 210 fourteen-mil and 7 thirty-three-mil (end) laminations. The inner and outer radii were 5.72 and 8.65 cm. respectively. The over-all core length was 11.20 cm. of which 72 per cent was net iron length. The total volume of the core was 1065 cu. cm.

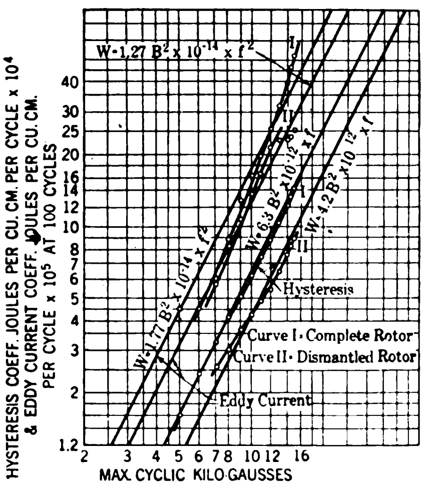

FIG. 16

By plotting data from Figs. 13 and 14 on logarithmic paper, representative equations for the core losses under alternating excitation were found to be, for the complete rotor:

Hysteresis loss
$= 5.3\ B^2 \times 10^{-12}$ joules per cu. cm. per cycle

Eddy loss
$= 1.77\ B^2 f \times 10^{-14}$ joules per cu. cm. per cycle

For the modified rotor:

Hysteresis loss
$= 4.2\ B^2 \times 10^{-12}$ joules per cu. cm. per cycle

Eddy loss
$= 1.27\ B^2 f \times 10^{-14}$ joules per cu. cm. per cycle

(B = max. flux density in gausses, f = frequency)

As Fig. 16 shows, the exponents of the density used in these formulas are not exact, but average values. The tests indicated a value of the eddy current exponent in excess of 2 and of the hysteresis exponent only a little less than 2. The reasons for the variable character of these exponents and the disagreement between observations by different investigators are probably to be found in the effect of the form of the magnetic path upon the wave form of flux variation. Although the total flux through the core undergoes a sinusoidal variation, the flux in each particular part of the core section undergoes its own form of non-sinusoidal variation which is determined by the variations in reluctance of the different sections during one cycle.[5]

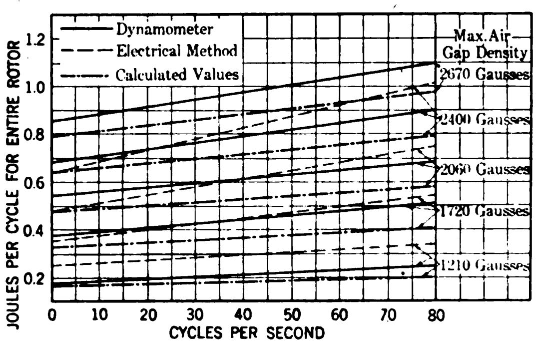

FIG. 17—CORE LOSS TORQUE VS. SPEED

Using the constants for the complete rotor thus determined, in connection with (**17**) and (**21**), the usual formulas for core loss, modified by multipliers K_1 and K_2 obtained from Figs. 2 and 3, the total hysteresis and eddy current losses were computed, added, and plotted on Fig. 17.

In these calculations the following constants were used:

$E = 4.42 \times 10^{-3}$ watts per cu. cm. at 50 cycles, 10,000 gausses.

$H = 3.15 \times 10^{-2}$ watts per cu. cm. at 50 cycles 10,000 gausses.

$a = Ra \div Ri = 1.51$

$L = 8.06$ cm.

$\phi = 47.0\ B_{max.}$ maxwells.

$B_{max.} = 4.11\ B_g$ maxwells.

B_g is the max. apparent gap density given in Figs. 9–11 inc.

$K_1 = 1.04$ (From Fig. 2. corresponding to $a = 1.51$, $P = 1$)

5. "Magnetic Flux Distribution in Annular Steel Laminae" by A. E. Kennelly and P. L. Alger, PROC. A. I. E. E. Dec. 1917, p. 1113.

$K_2 = 0.98$ (From Fig. 3. corresponding to $a = 1.51$, $P = 1$)

Inserting these constants in (**17**) and (**21**) there are obtained:

Eddy Loss

$= 1.95\, B_{max.}^2 f^2\, 10^{-11}$ watts for entire core.

Hysteresis Loss

$= 6.55\, B_{max.}^2 f\, 10^{-9}$ watts for entire core.

For the five excitations used in tests, the losses were calculated to be as follows:

D-c. Exc. amps.	3-1/2-7	5-10	6-12	7-14	8-16
F_g	1210	1720	2060	2400	2670
B max W 4.11 P_g	4970	7070	8470	9870	10990
Hyst. Watts/cycle/sec..	0.162	0.327	0.470	0.638	0.790
Eddy Watts/cycle/sec..	0.029	0.059	0.064	0.114	0.141
Total watts/cycle/sec. at 60 cyc............	0.191	0.386	0.554	0.752	0.931

A comparison of these calculated values with the test values, which are also shown in Fig. 17, brings out the fact that the former are uniformly too low. This is especially true in regard to the eddy current loss.

The real object of the investigation was to determine values of K_1 and K_2 by which the results given by the usual formulas should be multiplied to obtain correct results. Theoretical values of K_1 and K_2 based on the assumption of constant permeability were obtained and plotted in Figs. 2 and 3. These values give, at all points within the usual range of values of a and P in induction motor design practise, core losses not more than 10 per cent lower or 30 per cent higher than those given by the usual formulas. The test results are not accurate enough to obtain reliable values of K_1 and K_2 from, but they do show that the usual (as well as the new) formulas give a total core loss correct within 50 per cent.

The net result of the investigation is to establish a strong presumption that the cores back of the teeth are not the seat of any important extra losses and that the usual formulas (**17**) and (**21**) are sufficiently accurate for practical purposes, provided the correct iron loss coefficients, E and H are used in them. Due to the varying permeability, the true value of E is always larger than the apparent value derived from Epstein tests on straight samples or from the resistivity. But H is the more important of the two coefficients, and this is not much in error when obtained in the usual way.

As a general rule, the total core loss in an induction motor is from two to three times the calculated fundamental frequency losses in the core and teeth. Since it has been shown that probably no important part of these extra losses occur at fundamental frequency in the cores, and it seems evident that they can not be in any measure due to fundamental frequency flux inthe teeth, it appears that they are due to the tooth frequency pulsations. The probability, thus established, that the tooth frequency losses constitute from one-half to two-thirds of the total core loss in the average motor is of great importance. This shows at once the futility of calculating core losses without allowing for tooth frequency effects and also it shows the great possibilities that exist for the reduction of the core losses now tolerated. Slight changes in the numbers and shape of the teeth make large changes in the tooth frequency losses.

As a matter of fact, the total observed core losses can reasonably be accounted for by calculating the eddy and unsymmetrical hysteresis losses due to the tooth pulsations, and the pole face losses in the tips of the teeth due to the variation of gap density from tooth to slot, and adding these losses to the usually calculated fundamental frequency losses. In calculating the pulsation losses the copper losses and the damping effects of tooth frequency circulating currents in the rotor winding must be taken into account. The magnitudes of the undamped tooth pulsations may be quite accurately computed with the aid of Carter's formulas for fringing.

Review

To epitomize the work on the losses in a smooth annular core, it may be said that it was projected to determine a rational formula for these losses by the comparison of accurate experiments under controlled conditions with theoretical formulas, and that every step necessary to carry out that project was completed. At each step new sources of error were uncovered whose cumulative effect made it impossible to draw as detailed conclusions as had been planned. In short the work so far accomplished has provided only a part of the results aimed at.

To calculate the core loss theoretical formulas and empirical constants must be obtained. In developing a theoretical formula the errors of the usual formula (neglect of losses due to radial components of flux and assumption of uniform flux distribution) were avoided, but a new error (assumption of uniform permeability) was introduced by the lack of an adequate mathematical method of treatment. In determining the empirical constants the errors inherent in the usual method (attributing the properties of a sample of a different shape and possibly different lot of iron to the iron under test) were avoided by determining the constants for the test core directly. But the errors consequent upon the test core not being of the perfect annular shape ascribed to it were not avoided.

To measure the losses experimentally requires the development of an accurate method of measurement and of means of producing exactly the desired conditions of flux distribution. Two methods of measurement were developed and so far perfected as to give fair uniformity and agreement, though certain sources of error were not eliminated. The desired conditions of flux distribution were produced quite nearly by use of a carefully distributed 5/6-pitch

stator winding and a long air gap. The errors here, due to saturation and harmonics in the m. m. f., were satisfactorily small.

The only previously published paper that deals particularly with the fundamental frequency losses in a smooth-core rotor is, so far as known to the authors, that by R. Czepek in the *Elektrotechnik und Maschinenbau* for 1910, p. 325. In that article, Czepek described experiments on the losses in a smooth core produced by an alternating and by a revolving field. Comparing the results of his tests, Czepek concluded that the losses produced by a revolving field were considerably larger than those computed from constants derived from alternating magnetization tests; a conclusion distinctly opposed to that drawn from the results of the present paper. The reason for the disagreement in the conclusions probably lies in the fact that Czepek used a salient pole machine for his tests and that, consequently, the revolving field he used was quite far from sinusoidal. An oscillogram of the field wave form given in the article shows this distinctly.

In carrying out further work on core losses it will be very desirable to make use of larger machines, since the ratio of the friction and copper losses to the core loss, and hence also the errors in the separate measurement of core loss, are inherently greater the smaller the machine is. It will also be very desirable to develop an adequate mathematical treatment of the losses under variable permeability.

The element of the core loss that appears of greatest importance for future investigation is that due to pulsations in the teeth. The investigation of this loss should include first an investigation of the magnitudes and damping effects of circulating currents in the secondary, and second an extended investigation of unsymmetrical hysteresis. The subject of circulating currents due to tooth pulsations seems never to have been treated. That of unsymmetrical hysteresis is still open to discussion, since published researches have so far dealt only with the loss due to the addition of a small displaced hysteresis loop to the unchanged fundamental loop; while it is probable that the area of the latter loop is markedly changed by the presence of the former.

The principal definite results of the work on this research are:

(a) New formulas for the losses in the core back of the teeth have been developed, and multipliers for the usual formulas derived therefrom have been made available for convenient use by charting in Figs. 2 and 3. These charts indicate that the errors of the usual formulas due to neglect of the losses produced by the radial component of the core flux are not large except when excessively deep cores are used.

(b) Complete tests and calculations have been carried out on a smooth-core rotor revolving in a smooth stator and the observed losses compared with the expected losses, with the result of confirming the theoretical expectation that the errors of the usual formulas (**17**) and (**21**) are not serious in ordinary practise.

(c) As a result of (a) and (b) and the known fact that the total core losses in usual induction motors are from two to three times the fundamental frequency losses as calculated by the usual formulas, a strong presumption has been established that the tooth frequency core losses constitute from one-half to two-thirds of the total in ordinary induction motors.

(d) It has been experimentally demonstrated that the hysteresis torque due to a revolving field breaks abruptly through zero at synchronous speed. (Fig. 4.)

NATIONAL ELECTRICAL SAFETY CODE

The new edition of the National Electrical Safety Code is being printed by the Bureau of Standards. This code has been in the course of development for seven years. Preliminary drafts were circulated and criticized and the complete edition of the code was published in 1916 for trial use and constructive criticism. The new edition is expected to be made mandatory by state and city officials having appropriate jurisdiction. The rules of this code deal with the construction, installation and operation of electrical machinery and devices. They apply to practise in generating stations, to outdoor lines used in transmission and distribution, and to the installations of equipment found in factories, offices, theatres and other places where electrical energy may be applied.

MEETING AT PHILADELPHIA

FRIDAY, OCTOBER 8

The first Fall meeting of the American Institute of Electrical Engineers will be held in Philadelphia, Friday, October 8th.

The headquarters of the Institute during the meeting will be at the Bellevue-Stratford Hotel, Broad & Walnut Streets.

The afternoon session will begin at 2:30 p. m. in the Clover Room of the Bellevue-Stratford Hotel and two papers will be presented, as follows:

Economic Study of Secondary Distribution, by P. O. Reyneau and H. P. Seelye, both of the Detroit Edison Co.

Electrical Demand Measurements, by P. A. Borden, of the Ontario Power Commission.

At 6:30 p. m. an informal subscription dinner will be served to members and guests of the Institute in the Stratford Room of the Hotel.

The evening session will be devoted to the celebration of the 100th anniversary of the important early discoveries of Arago, Ampere, Davy and Oersted. The principal speakers at this session will be Dr. Elihu Thompson and Dr. M. I. Pupin.

Replicas of apparatus used by the pioneer discoverers in some of their experiments will be exhibited.

The Board of Directors of the Institute will hold its regular monthly meeting at 10:30 a. m. at the Bellevue-Stratford and a meeting of the Meetings and Papers Committee will be held at 9 a. m. Other committee meetings will be held in accordance to notices sent to committee members.

Program

FRIDAY, OCTOBER 8th

8:30 A. M.

Registration office opens.

9:00 A. M.

Meetings and Papers Committee.

10:30 P. M.

Meeting of Board of Directors.

2:30 P. M.

Technical Session

Economic Study of Secondary Distribution, by P. O. Reyneau and H. P. Seelye.

Electrical Demand Measurements, by P. A. Borden.

Discussion.

6:30 P. M.

Informal Subscription Dinner at Bellevue-Stratford. Price $3 per cover.

8:30 P. M.

Anniversary of Early Discoveries.

Address by Dr. Elihu Thomson.

The epoch making discoveries of the years 1819 *and* 1820 *with special reference to the work of Ampere, Arago, Davy and Oersted.*

Address, by Dr. M. I. Pupin.

The significance of the discoveries of Ampere, Arago, Davy and Oersted in the development of science in the past hundred years.

There will be exhibited replicas of apparatus used by the pioneer discoverers in some of their experiments which have been very kindly prepared for this occasion by Prof. Harold Pender.

NOVEMBER MEETING

The November meeting will be held in Chicago on November 12, 1920, and will be under the auspices of the Protective Devices Committee. The principal paper of the meeting will be by Mr. D. W. Roper, Chairman of the Committee, on the subject of Lightning Protection.

TELEPHONE STATISTICS SHOW BUSINESS DEVELOPMENT IN SOUTH AMERICA

Striking figures showing the development of South and Central American Republics are made public as a result of a survey by the American Telephone and Telegraph Company. These statistics, which were prepared with the cooperation of the various governments, cover the telephone and telegraph systems of all the countries south of the Rio Grande. Some of the conclusions reached from the survey are that in the Southern countries the telephone is far from being the universal means of communication that it is in this country and that the main development there is in the big cities, the other areas being very poorly served. The telephone network is about a hundred times as dense in this country, as a whole as it is there. In point of the number of telephones per hundred of population, the service here is over thirty times as good.

The total of 325,403 telephones in all the South and Central American countries including Cuba and Haiti, should be compared with the twelve million in the United States, which have about the same total population. Argentine leads with 105,205 telephones, or nearly a third of the total. The other countries having more than 10,000 telephones are: Brazil, 67,366; Mexico, 40,211; Cuba, 28,152; Chile, 23,670 and Uruguay, 19,486. Haiti with a total of 2,500,000 people, has 82 telephones.

Only one telephone for about every 300 population is found in the whole area, as compared with 11.39 for every hundred of population in the United States at the same date, or about 34 for every 300 population. Uruguay leads Latin-American countries in point of telephone density with 1.34 telephones per hundred people. The only other countries having as much as one telephone per hundred population are Argentine, Cuba and Panama. In the three countries having the highest telephone development, the systems are almost wholly under private ownership.

The extent to which the countries are served by their systems is indicated by the figures showing the telephone development in the largest city in each country. Havana, Cuba, is the most highly developed, with 5.5 telephones per hundred population. Taking in all of Cuba, however, there is only one telephone per hundred people. Mexico City has 3.9 per hundred—Mexico as a whole has only 0.25 telephones per hundred population. These figures show how in the Southern countries the bulk of the systems is in the large cities, while the other areas are hardly served at all. This condition is contrasted with that in the United States. At the same date New York City had 11.7 telephones per hundred people—the United States as a whole had nearly as many, 11.39. Here is adequate service for even the smallest farm communities.

The investment in telephone systems in all the Southern countries together is $64,422,000 compared with $1,600,000,000 in the United States. The per capita investment is 71 cents in South America compared with $15.09 here. The highest investment is in Cuba, $2.28 per capita. The investment per telephone is perhaps even more significant. In Latin-America there is invested $198 for every telephone in service—in the United States this is only $132. These figures reflect the higher technical progress and the more efficient mangement, as well as the greater density of development, in this country.

The gross earnings in 1918 of South American telephone systems were only eighteen cents per capita while in this country they were $3.99. The gross earnings per telephone were, however, $52.82 down there and only $34.98 here.

Of the total telephone and telegraph earnings in 1918 in the Latin countries, the telephones brought in only 43.5 per cent of the total and the telegraph 56.5 per cent. In the United States this situation is strikingly reversed—80.8 per cent from the telephones and 19.2 per cent from telegraphs. The total telegraph wire mileage is 433,938 down there and 1,900,000 here. The number of offices are 11,627 and 28,900 respectively. The number of messages sent in 1918 was 41,517,200 in the Southern countries as compared with 170,000,000 here.

The telegraph statistics therefore show a more favorable comparison with those of this country than do the telephone figures. The reason is that the telegraph is more used by a specialized class of the population mainly for business. The telephone has not in the Latin-American republics come anywhere near being the universal and democratic means of communication that it is in the United States.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

NATIONAL SERVICE DEPARTMENT OF ENGINEERING COUNCIL

When the Engineering Council announced that its National Service Department was prepared to assist engineers in obtaining such information as they wanted from the National Legislative and Executive Department. a great many engineers took advantage of this opportunity. Individual engineers as well as engineering organizations, will find the Washington office a useful medium, through which to keep in touch with National affairs and to bring their recommendations, their grievances or inquiries before government officers.

This is one of the important features that goes with membership in the A. I. E. E. and other societies which organized Engineering Council, and members should feel very free to call upon the Washington office whenever it can be of assistance. It is in charge of M. O. Leighton, National Service Representative of Engineering Council, 700 10th St. N. W., Washington, D. C.

TECHNICAL WORK AT THE BUREAU OF STANDARDS

Recent bulletins issued by the Bureau of Standards cover the progress of experimental work that has been started there. The titles of those that are of especial interest to engineers are itemized below: Permeability of Concrete.

Investigation of Combination of Aluminous and Siliceous Bond Clays Used in Making of Crucibles.

National Electrical Safety Code.

Method for the Accurate Measurement of the Interior Diameter of Ring Gages.

The Use of Etched Balls in the Brinell Test of Hardened Steels.

Properties of Boiler Plate at Elevated Temperatures.

Test of a Section of a Cast Iron Heating Boiler.

Because of the current nature of these investigations, the results are not generally printed, but complete data on all work to date is always obtainable through the National Service Department at the Washington office of Engineering Council, or from the Bureau direct.

ENGINEERING COUNCIL ADVISES THE FEDERAL POWER COMMISSION

At the invitation of O. C. Merrill, executive officer of the Federal Power Commission, the Water Conservation Committee of Engineering Council has submitted advice with respect to regulations covering certain important features of the administration of water powers, to be licensed under the Water Power Act. To Mr. Calvert Townley, Past-President of the American Institute of Electrical Engineers and also Chairman of the Water Conservation Committee of Engineering Council, Mr. Merrill submitted specific inquiries relating to rental charges for water power licenses, including charges covering cost of Federal administration, use of Government lands and property, tribal lands within Indian surveys and use of Government dams. Other inquiries were, the basis of exappropriation above a specific rate of return; readjustment of charges, benefits from headwater improvement, depreciation and amortization and finally allocation of earnings.

The Water Conservation Committee met at Washington on September 10th, spending the entire day in conference on the above named subject. The following day was spent in conference with the staff of the Federal Power Commission in discussing principles and points of view in preparation for the formal report of the Conservation Committee on the subjects.

The invitation given to Engineering Council to take up the above named matters in advisory capacity is but another of the instances which of late have become increasingly frequent, that the Government has recognized the value of organized engineering consideration in Government engineering matters.

FEDERATED AMERICAN ENGINEERING SOCIETIES

PROGRAM OF THE FIRST MEETING OF AMERICAN ENGINEERING COUNCIL

Washington, D. C., November 18-19, 1920

The headquarters of the meeting will be at the New Willard Hotel and all sessions will be held in the Small Ball Room.

Thursday, November 18, 1920

MORNING SESSION

8.30 A. M. Registration.

10.00 A. M. Opening Session of American Engineering Council

1. Call to order.
   Richard L. Humphrey, Chairman,
   Joint Conference Committee,
   Consulting Engineer,
   Philadelphia, Pa.
2. Election of Temporary Chairman.
3. Election of Temporary Secretary.
4. Appointment of Temporary Committees:
   (a) Program
   (b) Credentials
   (c) Constitution and By-Laws
   (d) Nominations
   (e) Plan and Scope
   (f) Budget
   (g) Resolutions.

AFTERNOON SESSION

2.00 P. M. Address, "Engineering Council," J. Parke Channing, Chairman, Consulting Engineer, New York, N. Y.

2.30 P. M. Discussion of the field of activity for The Federated American Engineering Societies.

Friday, November 19, 1920

MORNING SESSION

9.00 A. M.
1. Report of Committee on Nominations.
2. Election of Permanent Officers.
3. Report of Committee on Constitution and By-Laws.
4. Formal Ratification of Constitution and By-Laws.
5. Report of Committee on Plan and Scope.

AFTERNOON SESSION

2.00 P. M.
1. Report of Committee on Budget.
2. Report of Committee on Resolutions.

EVENING SESSION

8.30 P. M.
1. Introductory remarks by presiding officer, the President of American Engineering Council.
2. Address by Herbert C. Hoover, President, American Institute of Mining and Metallurgical Engineers, New York, N. Y.

9.30 P. M. Informal reception and smoker.

Saturday, November 20, 1920

9.00 A. M. Organization Meeting, Executive Board, American Engineering Council of The Federated American Engineering Societies.

ADDITIONAL SOCIETY ACTION

The Cleveland Engineering Society at its meeting on August 10 voted to become a Charter Member of The Federated American Engineering Societies.

EACH SOCIETY AUTONOMOUS

The manner of selecting representatives on the American Engineering Council has been criticized as being undemocratic and it is stated that,

The engineers of the United States today number at least 100,000—possibly 200,000. Within a decade or two it is not impossible that this may be increased to 500,000. Anything short of an effort to bring every one of these engineers individually into the fray by giving them a direct vote and otherwise, would be in the first place to go counter to every modern tendency in democratic theory, but of even greater immediate importance, it would deprive the new Federation of the most obvious means of educating and gradually enthusing the rank and file. This is just the kind of opportunity which was missed in the failure to provide that the members of the American Engineering Council should be elected by the votes of the members of the constituent organizations rather than by the boards of these organizations.

The Organizing Conference at Washington, by unanimous vote decided that the Federated American Engineering Societies

Should be an organization of Societies or affiliations and not of individuals.

The Constitution and By-Laws that it adopted provide that each organization shall be autonomous. In keeping with this principle of autonomy, it is the intent of the Constitution and By-laws that each representative on American Engineering Council shall be selected by the organization he represents in any manner it deems wise or expedient.

The Joint Conference Committee feels that the election of representatives by the direct votes of the members of each organization is desirable and should be supported in principle, but it is not a question that is vital at this time to the success of American Engineering Council.

If it were required that the representatives on American Engineering Council should be elected by the direct votes of the members of the constitutent organizations, many organizations would be obliged to delay becoming members for some time while changes were being effected in the Constitution and By-Laws of these organizations. As a matter of fact some of the organizations who have become members of The Federated American Engineering Societies will probably elect their representatives by the direct votes of the members of these organizations.

The Joint Conference Committee is confident that American Engineering Council, composed of representatives of national, local, state and regional organizations and affiliations from or representing all parts of the country, no matter in what manner they may be selected, will be truly a representative and democratic body free from the criticism that it does not properly and efficiently represent the engineering and allied technical professions.

FORM OF ORGANIZATION SATISFACTORY

In discussing the question of whether The Federated American Engineering Societies should be an organization of individuals or societies, a current bulletin of a local engineering society states,

We may infer * * * * * that the American Association of Engineers does not intend to enter the Federation and that we have here a distinct line of cleavage between a democratic and federalized organization. We are to choose which type of organization is to rule the destinies of the engineering profession. Our federal constitution provides for government of delegated powers composed of elected representatives, and we confess to a preference for that form of association of engineers modelled after that famous document which has been the model of the world for nearly a century and a half.

* * * * *

It would seem, therefore, that we have not yet brought about cooperation among engineers in its most effective form. Are we to be divided into two camps? It looks very much like it now.

As this statement is likely to be misleading, the Joint Conference Committee would point out that at the Organizing Conference in Washington, the delegates of the American Association of Engineers, which included its retiring and its incoming President, stated that,

We will cooperate on any basis you will permit us to cooperate upon. . . . We are here to support you, to give you all support, and insofar as we are able, our financial support in anything that will advance the welfare of the engineer.

The Joint Conference Committee does not feel that there is any danger of cleavage in the engineering profession, for the reason that one of the principles on which The Federated American Engineering Societies is founded is non-interference with the autonomy of each engineering and allied technical organization. The field of activity of this organization is that already undertaken by Engineering Council, which work will be extended and carried on in a more representative and comprehensive way. The Federated American Engineering Societies will not in any way be a competitor of existing organizations, and the Joint Conference Committee believe that its work will receive the hearty and effective cooperation of all engineering and allied technical organizations in this country. The most representative and important conference of engineers in the history of this country by unanimous vote decided on the present form of organization and it would seem logical, therefore, that the engineering and allied technical organizations should give it a trial and subsequently correct such defects as develop.

The Joint Conference Committee is confident that there are no defects in principle, but, as was pointed out at the Washington Organizing Conference details must obviously be subject to such changes as may, by experience, be found desirable.

The Joint Conference Committee appreciates that the conservative engineer wishes to weigh and consider, and be cautious about embarking on new enterprises. The Federated American Engineering Societies is not a new enterprise as has been repeatedly pointed out; the governing body of the organization, American Engineering Council, will succeed on or about January 1, 1921, Engineering Council which has as Member Societies the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Society for Testing Materials, and the American Railway Engineering Association. This organization, after three years of existence, is a proved success and has demonstrated the great need for a comprehensive body that will speak for the engineering and allied technical professions in matters of public welfare where engineering experience and technical training are involved, and in matters of common concern to these professions.

FINANCING THE FEDERATED AMERICAN ENGINEERING SOCIETIES

The Organizing Conference consisting of 140 delegates from 71 national, local, state and regional engineering and allied technical organizations and affiliations, representing an aggregate membership of over 110,000 or more than 80 per cent of that of all the organizations invited to participate, unanimously adopted the following resolutions, at Washington, June 3-4, 1920.

RESOLVED, that it is the sense of this Organizing Conference that an organization be created to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions.

RESOLVED, that it is the sense of this Conference that the proposed organization should be an organization of societies or affiliations and not of individuals.

The Joint Conference Committee in its report to its four constituent societies in September, 1919, unanimously recommended, the formation of a single comprehensive organization to secure united action of the engineering and allied technical professions in matters of common interest to them.

The Committee emphasized,—

that the plan can only be valuable and enduring as the motive dominating it is patriotic, broad-visioned and unselfish* * * *

The great object is to provide an effective body, widely and truly representative, modestly yet adequately financed, which will be neither autocratic nor aristocratic,* * * * * *.

The Committee pointed out the essential requirements of such an organization in the following recommendation:

Every new activity, to be effective, means work and needs money. A movement such as proposed, if undertaken without sufficient funds, would not only prove barren of results, but by failure would bring ridicule upon the profession. In advance of its organization no definite budget can be prepared. The revenues proposed are moderate, and are based on the experience of Engineering Council, which while called upon to occupy an ever-widening field, has been continually handicapped by limited resources.

As was pointed out previously, the annual income of Engineering Council never exceeded \$22,000. In considering the needs of the proposed organization, it was the unanimous opinion of the Joint Conference Committee and of the representatives of Engineering Council, that the minimum annual budget should be \$50,000. The reason for the larger budget for the proposed organization is that Engineering Council through the courtesy of the United Engineering Society, occupies quarters in the Engineering Societies Building free of charge and enjoys the services of a paid staff for which only a portion of their salaries are charged. When the American Engineering Council comes into existence, it must assume these expenses, which will be paid out of the contributions of its Member Societies. Another reason for the increase in this budget is that the Committee has been advised by the representatives of Engineering Council that its activities have been greatly curtailed because of the handicap of inadequate funds.

It was further deemed desirable, at least during the earlier years of the existence of the organization, that the representatives on the national council and the members of its Executive Board should be allowed mileage in order to insure a full attendance at meetings of these bodies; and allowance of \$25,000 was made for this purpose making a minimum annual budget of \$75,000.

The question then arose as to the best means of providing this income. It was agreed that the Member Societies of the organization should make contributions to cover the amount. The question naturally arose as to the basis for these contributions, since obviously a local society of 100 members could not reasonably be expected to make as large a contribution as a national society of several thousand members, nor could a national society of 300 or 400 members pay as large a contribution as one that had more than 10,000 members. The Committee took into further consideration, the ability of a local, state or regional organization or affiliation, to raise money as against that of a national society and it decided that the proportion paid by the former should be less than that paid by the national societies. In the final analysis the decision was reached that a proper basis of contribution would be the number of members in the organization, that is, an annual per capita basis, which was fixed for the national societies at \$1.50, and for the local, state and regional organizations and affiliations at two-thirds of this amount, or \$1.00 per member.

By reason of the fact that the individual member is the basis of assessment, some organizations make the mistake of assuming that there are individual dues in The Federated American Engineering Societies. Such is not the case. As above stated, each Member Society makes an annual contribution for the support of the work. This is determined on the pro rata basis per member indicated.

The basis of the contribution of a local, state or regional organization or affiliation member of The Federated American Engineering Societies, is the aggregate membership represented, with-

out regard to the fact that some of its members may be members of national organizations which are members of The Federated American Engineering Societies.

The basis of the contribution of a state organization to The Federated American Engineering Societies would be the aggregate membership in the state. If, however, one or more of the local organizations in the state already held membership in The Federated American Engineering Societies, then the basis of contribution of the state organization, would be the aggregate membership of the state, less the membership of the organizations which already held membership in The Federated American Engineering Societies.

The Committee has been frequently asked why the individual member should contribute more than once to the support of this organization. That is, if a member of a local organization holds membership in a national organization which is a member of The Federated American Engineering Societies, why should the local organization contribute again for him as a member of the local organization? The Joint Conference Committee considered the question of having the individual engineer and allied technologist interested in The Federated American Engineering Societies through the membership of the organization of which he was a member, and, whether it would be wise to make an individual assessment for dues of $5.00 per annum. If this plan of procedure had been followed the question that has just been discussed would not have arisen. On the other hand, the Committee felt it would work a hardship on some individuals, and, in its judgment when an engineer or allied technologist had advanced sufficiently in his profession to be able to join more than one society he would be in a position to pay a higher contribution per capita than the man who is a member of only one society. It, therefore, seemed logical, in lieu of a flat per capita assessment, to make the basis of a contribution of $1.50 in the case of a national organization and $1.00 in the case of a local, state or regional organization or affiliation. This undoubtedly means that the organizations of which the individual is a member must pay per capita contribution for him as above indicated; in the last analysis the per capita amount must be paid as many times as the individual is a member of organizations which hold membership in The Federated American Engineering Societies.

It is unreasonable that an engineer or allied technologist who has representation in The Federated American Engineering Societies through a national organization should expect also to have representation through a local or other organization that is a member of The Federated American Engineering Societies' without an additional payment for this representation. If he is a member of more than one organization that holds membership in The Federated American Engineering Societies, then he must pay for each representation.

Assuming an engineer is a member of six national and one local organization which have membership in The Federated American Engineering Societies he would contribute annually through his dues $10.00 to The Federated American Engineering Societies. The question that the individual engineer and allied technologist should ask himself is whether the advancement of the proper standing of his profession and the maintenance of a means whereby it is a factor in the affairs of the community, state, and nation, is worth an annual payment of this amount, even though he is a member of seven organizations which have membership in The Federated American Engineering Societies.

If the engineering and allied technical profession is to take its proper place in public affairs it must have some organization that will act as a medium for the expression of such service, and this organization must be financed. Each individual engineer or allied technologist should be willing to contribute at least $10.00 per annum for this cause, although, on the basis provided, the average per capita contribution will probably not exceed one-third of this amount.

SUMMARY OF INFORMATION

Who are and who should be interested. The Organizing Conference held in Washington, June 3-4, 1920 was attended by 140 delegates representing over 71 organizations, having an aggregate membership of over 110,000, or, over 80 per cent of the aggregate membership of all of the organizations that were invited. The questions have been asked:

"Who are these men?"
"Who were invited?"
"Who should be interested in this movement?"

The Federated American Engineering Societies is constituted of engineering and allied technical organizations, whose chief purpose is the advancement of the knowledge and practise of engineering and allied technical arts, which are not organized for commercial purposes. It includes the individual engineer and the allied technologist who is represented through the society or societies of which he is a member, which have membership in the organization. It includes civil, mining, metallurgical, mechanical, electrical, testing, railway, highway, municipal hydraulic, sanitary, water works, bridge, agricultural, illuminating, heating, ventilating, refrigerating, safety, radio, fire protection, automotive, industrial, military, marine, naval and chemical engineers, and architects, naval architects, chemists and geologists. These branches of engineering and allied sciences cover the whole range of activity in this country upon which is dependent its economic success. It has been said that, *everywhere you look you see the work that the engineer has done.*

Formation of The Federated American Engineering Societies. Engineers and allied technologists have been content to perform their work without notoriety. Dating from a period considerably before the war, the engineer was gradually developing class consciousness, and a desire to be of public service. This desire was intensified as a result of the World War and led to the formation of Engineering Council by the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers. In the effort of these societies to determine in what way their activities could be improved and rendered of greater value, committees were appointed by each, and these committees in turn appointed Conferees, who met and organized the Joint Conference Committee. As a result of this intensive desire for service, it was the unanimous opinion of the Joint Conference Committee that a comprehensive organization was desirable that could speak for the engineering and allied technical professions wherever engineering experience and technical training are involved, as well as in matters of common concern to these professions. This recommendation was accepted by the constituent societies who authorized the Committee to call, without delay, a conference of representatives of national, local, state, and regional engineering organizations and affiliations for the purpose of bringing into existence the comprehensive organization recommended. The Committee issued a call to 110 engineering and allied technical organizations for the thoroughly representative Organizing Conference of June 3-4, 1920, which has been characterized as the greatest event in the engineering history of this country.

This organizing conference without a dissenting vote, created The Federated American Engineering Societies and authorized the Joint Conference Committee to act as the Ad Interim Committee between its adjournment and the first meeting of its governing body, American Engineering Council.

Publications of the Joint Conference Committee. Immediately following the Conference, the Joint Conference Committee prepared an abstract of the proceedings of the Organizing Conference in Washington, copies of which were mailed to each of the organizations originally invited to participate and to the technical papers. The Committee was instrumental in securing the cooperation of the technical press and

through the courtesy of McGraw-Hill Company, Inc., published and distributed a sixty-four page booklet entitled *Engineers Unite*, setting forth, "The High Spots in the Washington Organizing Conference, June 3-4, 1920, as Reported and Interpreted by the Editors of the Technical Press," in the issues immediately following the Conference. The Committee issued a formal invitation to each organization, originally invited to the Organizing Conference, to become a Charter Member of The Federated American Engineering Societies, and to appoint delegates to the first meeting of American Engineering Council to be held in November of this year.

The Joint Conference Committee also edited and published in pamphlet form, the Constitution and By-Laws of The Federated American Engineering Societies, which have not only been distributed to the organizations invited to participate, but also to the technical press, and to others, and copies are available for general distribution.

The Joint Conference Committee received communications from the participating organizations and others asking for interpretations of the Constitution and By-Laws, or for explanation of matters pertaining to the movement, and as it was of the opinion that there were doubtless many others to whom the same information would be helpful, therefore, decided to issue Bulletins containing the information requested, which would be available to the organizations invited to participate, as well as to the technical press. Including this, nine Bulletins have been issued. These Bulletins first make announcement of Society action in the matter of membership in, and then answer mooted points in connection with, The Federated American Engineering Societies. Abstracts of these Bulletins have appeared in former issues of the JOURNAL.

Bulletin No. 1, issued July 9, announced the application for Charter Membership of the Technical Club of Dallas on June 22; the action at Montreal Canada, June 28-29, of the American Institute of Chemical Engineers in favorably referring to its Council the matter of becoming a Charter Member of The Federated American Engineering Societies; the action by the American Institute of Electrical Engineers at its Annual Convention at White Sulphur Springs, June 30; and the action taken by the Board of Direction of The American Institute of Mining and Metallurgical Engineers on June 25. The Bulletin also pointed out that the organization was not new; that the work of the body will be administered by American Engineering Council. It gave the resolutions adopted by American Engineering Council on June 17, endorsing The Federated American Engineering Societies and American Engineering Council, and authorizing its Executive Committee to proffer, on the part of Council, its services in establishing American Engineering Council.

Bulletin No. 2, issued July 16, emphasized the fact that the organization does deal with the interests of the individual engineer and allied technologist. It again stated that it was not a new organization; indicated how and why the name was selected; explained the basis of representation; showed that The Federated American Engineering Societies was supported by the contributions of Member Societies and that there was no provision for individual dues; pointed out that American Engineering Council is less cumbersome or unworkable than the present Engineering Council and that, further, it has the definite advantage of being more democratic and broader in its scope and membership. The bulletin also showed that the organization was conservatively financed; that it was democratic and not autocratic; and that there was an opportunity for whole-hearted support on the part of each engineer and allied technologist.

Bulletin No. 3, issued July 23, explained the purposes of The Federated American Engineering Societies; indicated what Engineering Council had done and pointed out what the organization would do, in addition to carrying on what Engineering Council was doing, in the advancement of the engineering and allied technical profession.

Bulletin No. 4, issued July 30, gave the story of the organization of The Federated American Engineering Societies in Washington, June 3-4, 1920 as reflected in excerpts from the editorial and other comment in the technical press, as compiled by the Joint Conference Committee.

Bulletin No. 5, issued August 13, announced the formal acceptance by the American Institute of Electrical Engineers of the invitation to be a Charter Member of The Federated American Engineering Societies and the pledging of its hearty cooperation in the work thereof. It explained the representation of local organizations; and pointed out that The Federated American Engineering Societies was already not only in existence but the largest engineering organization in this country. It also explained the membership requirements and showed that The Federated American Engineering Societies with the advantage of the combined prestige of all its Member Societies, will have a greater standing than any individual organization. It showed that the organization was representative and democratic and pointed out that the movement to federate the engineer and allied technologist was again to bear fruit in the formation of the federation of engineers and architects in the State of Minnesota.

Bulletin No. 6, issued August 20, announced the action by the Annual Convention of the American Society of Civil Engineers in Portland on August 10, in directing its Board of Direction to submit at once to letter ballot, the question, "Shall the American Society of Civil Engineers become a Charter Member of The Federated American Engineering Societies?" It also contained an answer to questions that had been propounded, namely, "If Engineering Council is a success, why should the proposed Federation supplant it?" and, "If Engineering Council is a failure, why should the Federation be organized along lines so nearly parallel?" It pointed out lessons to be learned from Engineering Council, showed that the Organizing Conference in its wisdom recognized the successes and the limitations of Engineering Council, and had evolved an organization in which all of these successes would be utilized and opportunity provided for more effective work on behalf of the engineer and allied technologist. It explained what organizations were invited to become Charter Members of The Federated American Engineering Societies and stated that the Joint Conference Committee did not maintain that the list was complete, that there may be other organizations than those on the list, eligible for membership, and that such organizations may make application for membership to the American Engineering Council. It also explained how members of the Executive Board are elected.

Bulletin No. 7, issued August 27, announced the formal acceptance by the Cleveland Engineering Society at its meeting of August 10 of the invitation to become a Charter Member of The Federated American Engineering Societies. This bulletin explained the manner of selecting representatives on American Engineering Council and that there was no way by which an organization could be compelled to elect them by popular vote of its members since under the provisions of the Constitution, each Society was autonomous and one of the fundamental principles in the call for the Organizing Conference in Washington, was the "non-interference with the interrelation with respect to technical matters, and the maintenance of the autonomy, functions and operations of individual organizations." The Joint Conference Committee felt while the election of representatives by direct vote was desirable, it did not consider the question vital at this time to the success of the American Engineering Council. It also explained why the form of organization was satisfactory.

Bulletin No. 8, issued September 3, was devoted to a detailed explanation of the method of financing The Federated American Engineering Societies. It pointed out that if the engineering and allied technical profession is to take its proper place in public affairs it must have some organization that will

act as a medium for the expression of such service, and this organization must be financed; and that each individual engineer and allied technologist should be willing to contribute at least $10.00 per annum for this cause, although on the basis provided. the average per capita contribution would not exceed one-third of this amount.

Bulletin No. 10, which appears in this issue contains the announcement of the first meeting of American Engineering Council and the program therefor. This without qualification will be a meeting of the greatest engineering organization in the world and as such will mark an epoch in the history of the engineering and allied technical professions. The Federated American Engineering Societies already has an aggregate membership greater than that of any other engineering organization in the world. As has been pointed out repeatedly, the question is not whether this organization will come into existence but the number of members it will have; it already is in existence, and the Joint Conference Committee as the Ad Interim Committee representing it is engaged in furnishing the organizations invited to become Charter Members with information and other assistance to enable them to act intelligently on the invitation. From the advices already received, the Committee can state that American Engineering Council will have a greater number of Member Societies than Engineering Council and will also represent a much larger aggregate membership—estimated considerably in excess of 60,000. The meeting of American Engineering Council in November will deal with the future work of the organization and determine the more important problems that should receive immediate attention. These problems will undoubtedly be those which will be the most helpful in rendering service to the community, state and nation.

SALE OF SURPLUS MATERIAL BY U. S. NAVY

The U. S. Navy Department has available a large supply of merchandise for immediate delivery, including cable, lamps, heaters and fixtures; and also an immense quantity of wire, cable, conduit, porcelain, insulators, boxes, generators, motors, etc., to be released in the near future. All of this equipment is new, in absolutely first class condition and in most cases in the original packing. Discounts are being allowed to quantity buyers.

Inquiries may be addressed to Mr. H. C. Hakes, Board of Survey, Appraisal and Sale; Third Naval District, Fleet Supply Base, 29th and 3rd Avenue, Brooklyn, N. Y.

CURRENT ENGINEERING TOPICS

CENSUS OF CENTRAL ELECTRIC LIGHT & POWER STATIONS

The printed report at the Census Bureau on Central Electric Light and Power Stations for 1917 was issued September 7th. This report is a part of a more complete report on the Electrical Industries which covers railways, telephones, telegraphs and municipal electric fire alarm and police signalling systems. Data for the report were obtained during the year 1918 for the fiscal year ending December 31, 1917. It is the most complete and valuable census taken on American Electrical Industries.

A partial census on Central Electric Stations was included in the census of manufacturers of 1890. This included only the State of New York and the City of St. Louis, so that results were not valuable for comparison with later periods. The fourteenth annual report of the Commissioner taken in 1898 was of great interest and significance, because it included 320 of the 460 known municipal plants and something over 25 per cent of the commercial plants then in existence.

The first complete census of electric light and power stations was taken in 1902 and comparative statistics are confined to that year and to the three quinquennial periods following. The same general form of schedule was used in each of these censuses.

The report which has just been issued covers the general development of Central Electric Light and Power Stations of both the steam and hydroelectric type. The general record of primary power equipment with special attention to generating equipment, line equipment and substation equipment is presented. Output and disposal of current are classified. Very comprehensive financial statistics are given with special comparative financial and operating summaries of selected groups of electric stations. Interesting data on employees, salaries and wages are also given.

Special features of this report are tabulations prepared with the idea of making it possible to study the aspects of the efficiency of commercial and municipal plants.

1. Relative amounts of current generated and purchased by commercial and municipal plants.

2. Stations have been grouped according to population of districts so as to show the density of surface for both light and power.

3. Groups of plants are taken to show the relative investments in electric stations per installed kilowatt capacity for both steam and hydroelectric plants, as well as for plants using gas and oil.

4. Selection and grouping of plants generating current by means of steam, water, gas and oil have been made to show the relative financial and physical efficiency of operation. For this purpose, plants are grouped according to quantity of current which they generate and according to their own use, whether commercial or municipal.

5. A comparison is made of several of the more important plants which purchase their current with those that generate their current. More particularly typical plants which generate no current have been grouped according to the amount of their output so that the relative efficiency of size and ownership can be studied.

VENTILATION OF VEHICULAR TUNNELS

Over a year ago the Bureau of Mines was asked by several of the Eastern cities to cooperate in a study of the effect of exhaust gases from automobiles in long tunnels. At that time Congress would not allow an appropriation for such work. It is believed that the next Congress, however, will give more attention to this subject and may be induced to make appropriations for the study of the whole matter of ventilation during construction and operation of tunnels, as well as making such appropriations as will permit of the study of gases in tunnels. It has become increasingly apparent that the increased amount of oxygen in compressed air causes a big fire hazard; therefore this phase of tunnel construction should be the subject of Government study. The Government, and especially the Bureau of Mines, is in a better position to gather the necessary data than any other agency.

There is an ever increasing amount of tunnel construction in the States—especially in the larger cities— the biggest project at the present time being the New York-Jersey City Tunnel. One of the other big tunnel projects at present under consideration is the six-mile double Moffat tunnel in Colorado which will permit the Moffat Railroad to go into Salt Lake City without encountering the otherwise prohibitive grades.

ENGINEERING FOUNDATION

RELATIONS, POLICY AND WORK

A. Why is engineering Foundation?

Because of need for research, other than researches of Government and large corporations, beyond the means of individual engineers, small companies and separate societies.

B. What has Engineering Foundation?

Endowment of $300,000, assurance of $250,000 more, an or-

ganization based on National engineering societies, and means for publicity.

C. What can Engineering Foundation do?

Receive and administer funds; support researches by individuals or organizations; establish and operate research laboratories; aid in applying to engineering results of research in the sciences; stimulate interest among engineers and the industries, and enlist support.

D. What are Engineering Foundation's relations to

(1) The Engineering Societies?

Joint agency for research; liaison with scientists, through National Research Council. Although the endowment is owned by United Engineering Society for its four founder Societies, the income is to be used "for the furtherance of research in science and engineering or for the advancement in any manner of the profession of engineering and the good of mankind".

(2) National Research Council?

Coöperation in stimulating and coordinating research by governmental, educational, industrial and private agencies.

(3) Division of Engineering, N. R. C.?

According to the "Organization" of N. R. C., the purpose of the Division may be stated: "To promote research and the application of the sciences to engineering". Engineering Foundation may use its funds "in any manner, for the furtherance of research in science and engineering". Therefore, Engineering Foundation may undertake any kind of work which the Division may undertake and others besides. Confusion can be avoided through the intimate relation between Foundation and Council and frequent communication between the officers of the Foundation and the Division. Even in their common field there is work enough for both: By agreement upon program from time to time, interferences will be escaped. The peculiar value of the Division arises from its being an integral part of National Research Council, the national federation of scientists and engineers for the promotion of research, and therefore being in a position to place before scientists engineering problems requiring scientific research and to inform engineers of activities of scientists which may affect engineering. Engineering Foundation can contribute to the support of the Division, can share in its deliberations through interlocking membership, can benefit from its work, and can have its advice as to researches which may profitably be supported by the Foundation. Independently, the Foundation may establish and maintain laboratories, support or conduct researches, and contribute results to the engineering societies. Foundation and Division each is essential to the engineering profession for purposes of research, but the activities of the two must always harmonize.

(4) Scientific Bureaus of Government?

Exchange information; make more available to engineers results of researches by bureaus; suggest to bureaus how to make their researches more helpful.

(5) Consulting and Industrial Laboratories?

Cooperation to make available to them results of research by Foundation and societies, and to obtain for general use, results of their researches.

(6) Engineering Societies Library?

Aid in making this library the repository of all information about research relative to engineering.

E. What needs can Engineering Foundation supply better than any other organization?

Direction and support of research relative to engineering, of such nature as not to be undertaken by an industrial corporation, the Government, nor a university; collection and publication of information about research of particular interest to engineers, utilizing engineering journals.

F. Should Engineering Foundation establish an Engineering Research Institute and Laboratory?

Yes: to supplement the university training of prominent research men; to provide place and means for research by engineers and inventors and for limited cooperative research for industries. The laboratory might be made partially self-sustaining. For some kinds of work or training, charges might be made, particularly for those not of general interest, and for those from which profits will be realized. An establishment under Engineering Foundation would have an independence and celerity of action not feasible in a governmental laboratory and would be able to conduct researches on a scale and in an atmosphere of practical requirements not possible in a university. In the course of years, there might be more than one laboratory, each situated where it would have the best conditions and be most useful.

G. What are Engineering Foundation's needs?

Immediately, a half-million dollars, and, as its work develops, further additions to endowment; funds for establishment and maintenance of an engineering research institute and laboratory.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

THE UNITED STATES CIVIL SERVICE COMMISSION announces an open competitive examination for electrical engineering aid. Vacancies in the Bureau of Mines, Department of the Interior, for duty at Pittsburgh, Pa., or elsewhere, at entrance salaries ranging from $1,200 to $1,680 a year, and vacancies in positions requiring similar qualifications at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. On account of the needs of the service applications will be received until further notice. Z-2130.

MECHANICAL ENGINEER with wide experience in industrial plant layout and factory production work. Preferably with experience on steam heating boilers, radiators, etc. Should have good knowledge of conveying equipment. Must also have good experience along production lines and be able to supervise the setting of piece rates, bonus systems, incentives. Location N. Y. City. Z-2095.

SALES ENGINEER FOR ILLUMINATING WORK wanted by large fixture manufacturer having standardized line. Capable aggressive salesman well versed in general illuminating practise. Location New York City. Z-2078.

BOILER DESIGNER AND TROUBLE SHOOTER for large company manufacturing house heating boilers. Experienced men only. Application by letter, giving detail information. Location New York State. Z-2085.

TECHNICAL GRADUATE familiar with electrical equipment in steel mills, who wishes to be associated with the design of this apparatus. State age, technical training and experience. Location Pa. Z-2086.

ELECTRICAL ENGINEER to assist in development of induction and series fan motors. Preference given to man accustomed

to working with detail mechanical apparatus. State age, experience and salary desired. Location Pennsylvania. Z-2056.

Industrial Physician, preferably young man who has had some experience, has a leaning toward that work and a man with enough initiative to organize and supervise department with two or three assistants. Location New York. Z-2057.

Assistant Plant Manager. Must be graduate Mechanical Engineer with a thorough knowledge of Electricity and three to five years experience. Must also be a good executive and able to handle men. The position is with a large bottle company in Ohio. There is a good opportunity for advancement. Man between 30–40 preferred. Location Ohio. Z-2058.

Designer for steam and electric power plants, not a drafting position. Must be able to make calculations on power station design and economics and be a graduate from a high grade technical school. Permanent position. Two men needed. Application by letter only. Location New York City. Z-2044.

General Foreman for boiler shop. Must be man of broad boiler manufacturing experience. Good executive ability, able to direct efforts of two hundred men. Must know boiler details to the last degree. Salary to suit proper man. Location Erie, Pa. Z-2049.

Operating Electrical Engineer for sugar plantations in Cuba. The total kilowatt output of this factory is 1875 at 440 volts. The duties of this engineer would be maintenance and operation and we would be willing to take a bright young man who possibly has been out of school two or three years for this service. Location Cuba. Z-1974.

Boiler Salesman, preferably one handling Horizontal Return Tubular Boilers at present. To work either on salary and commission, or straight commission basis, in the New York market. We have a good opportunity for a thoroughly experienced boiler salesman, one who can get results with a line manufactured to Massachusetts Standard. Location New York. Z-1975.

Salesmen for lubricating oils in foreign fields. Men who are thoroughly familiar with marketing abroad in general, even though they have no lubricating engineering training. Z-1949.

Young Man for meter department, large public utility holdings, offering excellent opportunities for advancement. Applicant must be willing to help out in any department. Man with High School Education preferred. Only men who are reliable and willing to work up need apply. Location Mass. Z-1954.

Assistant Supervisor for printing department of a large corporation. Must have experience in printing technique. and be familiar with office management as work will consist largely of forms, papers, etc., for modern office systems. Age 29 to 40. Location New York State. Z-1875.

Designer, mechanical designer with practical experience on electric switching apparatus. Permanent work for the right man. State age, experience, education and salary expected. Location Pennsylvania. Z-1795.

MEN AVAILABLE

Young Man single, technical education, 6 years experience in Electrical Engineering Work (laboratory, office and construction) desires position offering greater responsibility and future. Location desired, New York or Baltimore districts. Available in one month. E-2343.

Electrical Engineer, technical, 32, married, 8 years experience including design, manufacture, construction and operation. Office and field executive. Location Middle States. Salary $3600 per annum. E-2344.

Electrical and Mechanical Engineer, Indian, age 29, now in India, is desirous of proceeding to America, location New York or vicinity. Eleven years experience in a-c. & d-c. works, steam and hydroelectric power stations, overhead and underground transmission and workshops. Position of responsibility and with consulting or contracting engineers preferred. $5000 and passage found. E-2345.

Graduate Electrical Engineer, (1915) age 27, desires position of greater responsibility with opportunity for advancement. Considerable experience in steam turbines and condensers also all round power plant operation. Three years experience in the testing laboratories of two large public utilities. Available at once. E-2346.

Graduate Electrical Engineer, age 24, single, with 2 years experience in the various phases of electric distribution and construction work. Desires change offering broader opportunities and larger salary. Will consider anything anywhere, offering a real future. E-2347.

Young Man, training, General Electric Company test, desires connection with firm doing commercial engineering for Spanish speaking countries. E-2348.

Electrical Engineer, technical graduate with two years practical experience; including sub-stations and bus car constructions, also transmission line, power house and concrete work. Am experienced in handling men. Desires position where good honest effort is appreciated. Salary $200. E-2349.

Electric Power Expert, 27 years experience on nearly all phases of electric power supply. Have specialized for many years on examination and critical analysis of the financial and engineering sides of existing and proposed undertakings studies of "power market" and of the comparative cost of power production from alternative sources in U. S. and Canada. E-2350.

Electrical Engineer, 36, married. Technical graduate, four years General Electric test, nine years construction, operation and maintenance of transmission lines substations, and steam turbine power plant, and various modern applications, of electricity to the mining of coal. Available on 30 days notice. E-2352.

Engineer, with 22 years practical experience in electrical and mechanical engineering work, age 42, desires engagement on hydroelectric power work in South America. Excellent personality, energetic, first class references. Available on short notice. E-2353.

Executive, resourceful and tactful. Broad engineering and manufacturing experience and familiar with modern business methods. Desire connection with growing concern. Age 36, married, pleasing personality, and in excellent health. Salary at fixed sum or fixed sum and percentage of savings effected. E-2354.

Executive, University education, broad business experience. Industrial Engineering manufacturing, commercial investigations, financial reports, earning, power, cost-engineering, accounting, organization, sales. Available on reasonable notice, for association with firm of manufacturers industrial engineers, accountants, or with high grade banking house. Salary $6000. Prefer salary basis with profit-sharing proportionate to results. E-2355.

Graduate Electrical Engineer, age 32, member A. I. E. E. Extended research and executive experience. Desire position in research or manufacturing. Location no object. E-2356.

Electro-Mechanic; Cornell, 25, four years broad experience including two years G. E. test. Must locate in the immediate vicinity of New York City; desire position requiring good engineering sense and business ability combined with good opportunity for advancement. Small growing concern preferred. E-2357.

Vice President and General Manager, electric, gas, and water properties, 15 years construction, operation and development of small properties. Can prove satisfactory services to stockholders, directors and the public. Desires connection with larger utility or Holding Company. Age 45, married. Present salary $6000. E-2358.

Electrical Engineer, Technically trained, five years experience in circuits, conduit layouts and equipment of central stations and telephone plant desires connection with a manufacturing plant in either an executive or sales capacity. Capable of supervising the electrification of an industrial plant. Vicinity of Philadelphia preferred. E-2359.

Technically Trained Engineer Executive, age 27, single, present manager public service company in city of 10,000 north central west. Experience includes six years construction and operation hydroelectric and steam power plants, transmission lines, etc. Two years officer in Corps of Engineers, U. S. Army. Interested in offer on installation or management project requiring imagination and responsibility in Western United States or Far East. Opportunity most important consideration. Available November 1st. E-2360.

GRADUATE ELECTRICAL ENGINEER, four years experience in telephone and power plant design, construction, and installation, desires connection which will make location abroad imperative. Speaks French. Minimum salary $3,750. E-2361.

TECHNICAL GRADUATE, (E. E.) Nine years in charge of electrical departments for largest industrial incorporations. Nine years chief engineer or assistant engineer on Public Service Commission and valuation work; wishes position as manager or operating superintendent of Public Utility Company or with good company on valuation work. E-2362.

ENGINEER AND EXECUTIVE, desire engagement. Technical graduate, experience, 6 years in electric light and power business as assistant to general superintendent and as division manager, one year in federal employ in responsible capacity operating highly technical gas plant, 1½ years as engineer and chief engineer of large oil corporation, construction of pipe lines, pumping stations, oil loading terminals, etc. E-2263.

CHIEF ELECTRICIAN, 12 years experience on maintenance, construction, installation and testing of all classes of industrial apparatus. Both a-c. and d-c. technical training. Can handle large force of men. Married, age 30. Available at once. Eastern Pennsylvania or New Jersey desired. E-2364.

TECHNICAL GRADUATE, four years laboratory experience in magnetics, thoroughly versed in modern methods of testing electrical steels and materials, desires position with manufacturing concern in need of man with the above training and experience. Salary commensurate with duties and location. Available on reasonable notice to present employer. Married, age 30. E-2365.

OPERATING MANAGER, wishes to negotiate with Public Utility Company. Thorough knowledge in operation of Electrical and Gas properties. Experience twelve years technical engineering and construction; five years operating manager, combination gas and electric plants. Thoroughly versed in rate making and handling municipal and public matters. Salary dependent upon size of properties and location. E-2366.

ELECTRICAL ENGINEER, 31, married. M. E. degree. Nine years experience in public utility work desires connection with consulting or manufacturing firm. Experience in executive, operating and maintenance work, as superintendent and manager, in charge of power plant, distribution system and street railways. Salary $3600. E-2367.

CHIEF ELECTRICIAN OR FOREMEN, 35, good executive, 18 years technical and practical experience a-c. & d-c. stations. Underground distribution and motor work. familiar time study systems. Systematic hustler, natural leader. Desires position in Building—Factory, or Shipyard. Best reference. At present employed. Available on reasonable notice. E-2368.

ELECTRICAL ENGINEER, with university degree and 10 years engineering experience including 2½ years in test and service departments of Westinghouse Electric Company desires a permanent location with chance for advancement. Electric Railway contractor, or public utility in Middle West preferred. Age 30, married. E-2369.

MAGNETIC MATERIALS ENGINEER, desires responsible position concerned with magnetic work, or with electrical laboratory work. Have 10 years experience laboratory measurement in electrical, magnetic, and research work. With G. E. Standardizing Laboratory (Lynn) 3 years; last position 4½ years large magneto company in charge magnetic tests, electrical laboratory, oscillographic work, etc. Thorough technical education; age 34; single; minimum salary $2600; available early part 1921. New York, New England or far west preferred. No subordinate positions considered. E-2370.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street,

1. James F. Elliott, Electric Controller & Manufacturing Co., Oliver Building, Pittsburgh, Pa.
2. Wilmer K. Graeff, 533 Muriel Parkway, Elizabeth, N. J.
3. Oliver H. Horner, c/o Black & Veatch, 507 Interstate Bldg., Kansas City, Mo.
4. Wilfred Langille, Marion Station, Publice Service Electric Co., Jersey City, N. J.
5. Alex. E. E. Mayo, Carnegie Institute of Technology, Pittsburgh, Pa.
6. P. J. Reese, 7th & Main Street, Royal Oak, Mich.
7. Harry Symes, Lyne Manufacturing Co., Orange, Va.

PERSONAL

A. G. JANES has changed from the Standard Steel Castings Co., Cleveland, Ohio. to become Superintendent of Maintenance with the Interstate Foundry Co., Clearing, Illinois.

ROBERT T. LOZIER of Chicago was married on August 7th at Northport, L. I., to Lucille Scheffler, daughter of Mr. and Mrs. Frederick A. Scheffler.

M. L. HASELTON, formerly with the Westinghouse Electric and Mfg. Co., has accepted a position as Assistant to G. L. Knight, Designing Engineer of the Brooklyn Edison Company, Brooklyn, N. Y.

S. F. SHAW has resigned as Superintendent for the American Smelting and Refining Co., at Charcas, S. L. P. to accept a position as Manager of the Cia, Mra. La Constancia, at Sierra Mojada, Coahuila, Mexico.

GANO DUNN, Past President of the Institute and President of the J. G. White Engineering Corporation was married on August 26th to Mrs. Julia Gardiner Gayley of New York, daughter of the late Curtis Crane Gardiner of Gardiner's Island.

E. A. BROFOS, who has been representing the Western Electric Company in Northern Europe for several years, has been appointed manager of a new Norwegian corporation to handle all of the Scandinavian business of the International Western Electric Company. This will be known as the Western Electric Norsk Aktiesekskap, and its headquarters will be located in Christiania.

OBITUARY

DR. SAMUEL SHELDON, Past President of the American Institute of Electrical Engineers and Professor of Physics and Electrical Engineering for 31 years at The Polytechnic Institute of Brooklyn, died on Saturday evening, September 4th of Brights' disease at the Addison House, Middlebury, Vt. With him at the time of his death were his only son, Samuel Sheldon, Jr., of Brooklyn and his only surviving sister, Mrs. Susan B. Miner of Middlebury. The services and burial took place in Middlebury, where his wife, who was Frances Warner Putnam of Brooklyn, died in 1914.

Dr. Sheldon was born in Middlebury on March 8, 1862, the son of Harmon Alexander and Mary Bass Sheldon. He was graduated from Middlebury College in 1883 with the degree of A. B. and then pursued graduate work, receiving the degree of A. M. in 1886. During the next two years he studied at Wurzburg, Germany, and received the degree of Doctor of Philosophy there in 1888. During a part of this time he was associated with Kohlrausch, the distinguished physicist, in his celebrated determination of the ohm as the unit of electrical resistance. He was awarded the honorary degree of Doctor of Science from the University of Pennsylvania in 1906, and from Middlebury College in 1911.

Dr. Sheldon went to the Polytechnic Institute of Brooklyn in 1889, after a year spent at Harvard as instructor of physics, and was immediately honored with a full professorship in physics and electrical engineering. He was then in his 27th year. His thorough command of his subjects, together with the enthusiasm and energy which he exhibited in the lecture room,

gained for him a reputation as one of the foremost educators in the engineering profession. His strong points as a teacher were his inspiring and sympathetic personality, keen analytical mind, executive and cooperative ability, and tremendous capacity for work. Illness in 1909 necessitated a long vacation, and he chose to spend it in a trip to Europe, where he had an opportunity to visit the principal engineering schools of Germany, the British Isles, France and Italy.

Over 1,000 graduates of the Polytechnic received instruction from Dr. Sheldon and a majority of them held him in such affectionate regard that he was popularly known to them as "Sammy." Many of his former students became men of renown in the engineering world. Among them are Bancroft Gherardi, vice president and chief engineer of the American Telephone and Telegraph Company, and Arthur W. Berresford, President of the American Institute of Electrical Engineers.

Dr. Sheldon was the author and joint author of several college text-books. Among them were "Direct-Current Machines," "Alternating-Current Machinery," "Electric Traction and Transmission Engineering" and "Physical Laboratory Experiments." He had also written a number of monographs and papers on special topics.

Dr. Sheldon was elected an Associate in the A. I. E. E., in 1890 and transferred to Member in 1891, and to Fellow grade in 1913. He was elected President of the Institute for the year 1906-07. During his many years of connection with the Institute, Dr. Sheldon always showed an intense interest in its welfare, and gave unstintedly of his services and advice to the many committees on which he served. From 1898 to 1909 he was a Director of the Institute; from 1902-06, Chairman of the Meetings and Papers Committee; 1908-09, Chairman Standards Committee; 1910, Chairman, Library Committee; on Committee Cooperative Research, 1898-1900. Reception Committee 1900; Local Organizations Committee, 1902-03;. By-laws Committee, 1903-04; Executive Committee 1906-07; Committee on Code of Ethics, 1908-09. Dr. Sheldon represented the Institute on the Committee of International Electrotechnical Commission, 1911-12; the John Fritz Medal Association of which he was Past President; the Joint Committee of the Society for the Promotion of Engineering Education; the American Association for the Advancement of Science; the International Congress of Applied Chemistry. He became a Trustee of the United Engineering Society, representing the Institute, in 1916. He was elected its Assistant-Treasurer in that year and held that office until his death. He was Chairman of the Library Board for 1915-16 and Vice Chairman for the current year. At the time of his death Dr. Sheldon was also a member of the Committee on Geographical Divisions and Electric Procedure and Chairman of the Law Committee.

Among other activities with which Dr. Sheldon was connected might be mentioned: New York Electrical Society (Past President); American Physical Society; American Electrochemical Society (Past Manager); National Electric Light Association; Interurban Street Railway Association.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES AUGUST 1-31, 1920.

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

CORRECTION.

The price of "Graphic Production Control" by C. E. Knoeppel, is $10.

WIRING FOR LIGHT AND POWER.

A Detailed and Fully Illustrated Commentary on the National Electrical Code. By Terrell Croft. Second edition. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 465 pp., illus., tables, 8 x 5 in., flexible cloth, $3.

The purpose of this book is to supply explanations, elaborations and illustrations for those sections of the National Electrical Code to which most frequent reference is necessary. For this purpose the most important Code regulations are given verbatim, and their application in practical electrical construction is explained by supplementary text and drawings. This edition has been fully revised to correspond with the 1918 edition of the Code.

ACCOUNTS IN THEORY AND PRACTISE. PRINCIPLES.

By Earl A. Saliers. First edition. N. Y. and London McGraw-Hill Book Co., Inc., 1920. 301 pp., 9 x 6 in., cloth, $3.

CONTENTS: Fundamental Principles; Partnership Accounting; Expansion of Accounting Records; Corporation Accounting; Financial Statements; Special Application of Principles.

This volume, by an assistant professor of accounting in the Sheffield Scientific School is intended as an introduction to the principles of accounts. An attempt has been made to attain an effective combination of theoretical discussion and practical application. Bibliographies are given with each section of the book.

ANALYSIS OF PAINT VEHICLES, JAPANS AND VARNISHES.

By Clifford Dyer Holley. N. Y., John Wiley and Sons, Inc.; Lond., Chapman and Hall, Ltd., 1920. 203 pp., illus., tables, 8 x 6 in., cloth, $2.50.

The author, an experienced paint chemist, presents the methods used in his laboratory for the systematic examination of paint vehicles.

THE BUSINESS MAN AND HIS BANK.

By William H. Kniffin. First edition. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 278 pp., illus., 8 x 6 in., cloth, $3.

This volume treats banking from the viewpoint of the customer and is intended to assist the business man to that knowledge

which will enable him to select his bank, to make proper use of it and to understand the ways in which it can aid him in his business.

A COURSE IN ELECTRICAL ENGINEERING.

Volume 1. Direct Currents. By Chester L. Dawes. First edition. N. Y., and London, McGraw-Hill Book Co., Inc., 1920. 496 pp., illus., 8 x 6 in., cloth, $4.

The present book is the first of two volumes which are intended to serve as a comprehensive text covering the general field of electrical engineering in a simple manner. It will be useful, the author believes, to students of electrical engineering as an introduction to more advanced texts and also to students who are studying the subject for general training, without the intention of becoming specialists. The treatment is detailed, straightforward and systematic, but avoids much mathematical analysis.

THE DESIGN OF HIGHWAY BRIDGES OF STEEL, TIMBER AND CONCRETE.

By Milo S. Ketchum. Second edition rewritten. N. Y., McGraw-Hill Book Co., Inc.; London, Hill Publishing Co., 1920. 548 pp., illus., diagrams, charts, tables, 9 x 6 in., flexible cloth, $6.

This new edition has been made necessary by the increase in live loads due to the extensive use of heavy motor trucks and tractors, and the increased use of reinforced concrete in highway bridge construction. The scope of the book has been extended to include the design of concrete and timber bridges as well as steel bridges. The discussion covers all the details of constructing highway bridges. This edition is uniform with the author's "Structural Engineers' Handbook."

DREDGING ENGINEERING.

By F. Lester Simon. First edition. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 182 pp., illus., plate, tables, 9 x 6 in., cloth, $2.50.

The author of this volume has attempted to supply a work which will describe the principal types of dredges in such a manner as to impart a fundamental working knowledge of their construction and operation, He also takes up concisely the problems that confront the engineer in the conception and accomplishment of dredging projects.

EARTHWORK AND ITS COST.

A Handbook of Earth Excavation. By Halbert Powers Gillette. Third edition. N. Y., McGraw-Hill Book Co., Inc.; Lond., Hill Publishing Co., Ltd., 1920. 1346 pp., illus., tables, 7 x 5 in., flexible cloth, $6.

This treatise covers systematically and comprehensively the methods of excavating for engineering work of all kinds. In addition to the results of his own experience, the author has included a summary of the material in American technical literature. Particular attention is given to cost data. The present edition has been revised.

FLUGTECHNIK: GRUNDLAGEN DES KUNSTFLUGES.

By Arthur Pröll. München and Berlin, R. Oldenbourg, 1919. 332 pp., illus., 9 x 12 in., paper, 30.25 marks (33 marks, bound).

This treatise is founded on manual of the scientific foundations of the subject, prepared for practical self-instruction, while the author was director of the aeronautical experiment station of the Austrian war ministry. The notes prepared for this purpose were used later in connection with his lectures on technical aerodynamics in the Hannover High School, from which the present work has been prepared. The book, therefore, presents the subject from the viewpoint of immediate practical usefulness and also emphasizes the connection of aeronautical calculations with the teachings of mechanics. It will serve, the author believes, not only as a text for students, but will also enable the experienced engineer to carry out designs and construction in all details, when combined with practical numerical data. The discussion is confined to monoplanes and biplanes of the usual type.

HENLEY'S TWENTIETH CENTURY FORMULAS, RECIPES AND PROCESSES.

Containing Ten Thousand Selected Household and Workshop Formulas, Recipes, Processes and Money-saving Methods for the Practical Use of Manufacturers, Mechanics, Housekeepers and Home Workers.

Edited by Gardner D. Hiscox. 1920 edition, revised and enlarged, N. Y., The Norman W. Henley Publishing Co., 1920. 807 pp., 9 x 6 in., cloth, $5.

The formulas in this volume cover a wide range of manufactures and operations. They have been collected from a variety of sources, special attention having been paid to foreign publications not usually available. In this edition the work has been modernized.

HOW TO MANAGE MEN.

The Principles of Employing labor. By E. H. Fish. N. Y., The Engineering Magazine Co., 1920. 337 pp., 9 x 6 in., cloth, $5.

This book is a discussion of the relations between workers and their employers, in which an attempt is made to evaluate the things that go to make a satisfactory working organization. The author discusses the establishment of an employment department, the problems of the employment manager, the promotion of industrial relations, and industrial education.

THE IRON AND STEEL INDUSTRY OF THE UNITED KINGDOM UNDER WAR CONDITIONS.

A Record of the Work of the Iron and Steel Production Department of the Ministry of Munitions. By F. H. Hatch. London, privately printed for Sir John Hunter by Harrison and Sons, 1919. 167 pp., illus., plates, portraits, charts, tables, 10 x 6 in., cloth, (gift of author).

This volume is an interesting account of the methods used by the British Government to obtain the necessary increase in the steel production of Great Britain during the war. The vastness of the field covered, the variety and complexity of the technical problems involved and the far-reaching industrial questions raised, made the subject one of great interest and importance.

MACRAE'S BLUE BOOK.

Chicago and N. Y., MacRae's Blue Book Co., 1920. 1853 pp., 11 x 9 in., cloth, $10.

An alphabetically arranged directory of American manufacturers, which is especially full with respect to iron and steel products, and the materials used by railways and in building. In addition to the directory of materials, it contains a list of addresses, and also of trade names, a standard list of prices and a collection of data used by buyers. Thirty thousand firms are included.

MARINE ENGINEERS' HANDBOOK.

Prepared by a staff of specialists, Frank Ward Sterling, Editor-in-Chief. First edition. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 1486 pp., illus., tables, 7 x 5 in., flexible cloth, $7.

This handbook is compiled for the use of operating and designing engineers, and students. To cover the main subjects and the many ramifications of marine engineering, it has been necessary to enlist the services of thirty specialists, each of whom has received the hearty cooperation of others in the same field. The best endeavor has been made to coordinate different practises in order that all data may be reliable and unbiassed. The handbook is a pioneer in its field.

MATHEMATICS FOR ENGINEERS.

Part II. By W. N. Rose. N.Y., E. P. Dutton and Co., 1920. 419 pp., illus., tables, 9 x 6 in., cloth, $7.

The work of which this is the second volume is intended to occupy a position midway between those written for college students, which are usually academic in character, and those practical books which omit any discussion of the scientific basis underlying them. It is intended to contain all the mathematical work needed by engineers in their practice and by students of all branches of engineering. This volume treats of the differential and integral calculus, spherical trigonometry and mathematical probability.

MINE BOOKKEEPING.

A Comprehensive System of Records and Account for Mining Operations of Moderate Dimensions. By Robert McGarraugh. First edition. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 118 pp., illus., 9 x 6 in., cloth, $2.

This discussion of mine accounting is intended to show a system of records and accounts adequate for small mines, where the elaborate systems necessary for large-scale operations would require too large a clerical staff.

PERSONNEL ADMINISTRATION.

Its Principles and Practise. By Ordway Tead and Henry C. Metcalf. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 538 pp., 9 x 6 in., cloth, $5.

The purpose of this book is to set forth the principles and the best prevailing practise in the field of the administration of human relations in industry. It is addressed to employers, personnel executives, employment managers and students of personnel administration, but will have value, the authors hope, also for all who are interested in advancing right human relations in industry and in securing a productivity that is due to willing human cooperation, interest and creative power. The field covered includes those efforts usually included in personnel management: employment, health, and safety, training, personnel relations, service features and joint relations. The book also seeks to show the relation of the personnel problems of each corporation to those of its industry as a whole, by considering the activities of employers' associations and organizations of workers.

RAILROAD CURVES AND EARTHWORK.

By C. Frank Allen. Sixth edition, revised. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 289 pp., diagrams, charts, tables, 7 x 4 in., flexible cloth, $4.

This book has been prepared for the use of the students in the author's classes at the Massachusetts Institute of Technology, but it will also, he believes, be useful to engineers who have to deal with earthwork computation or curves.

The new edition is marked by an extension of the treatment of circular arcs; by new methods for the computation of earthwork, additional data on haul, and by general revision.

SHOP PRACTISE FOR HOME MECHANICS.

Use of Tools: Shop Practises: Construction of Small Machines. By Raymond Francis Yates. N. Y., The Norman W. Henley Publishing Co., 1920. 320 pp., illus., 9 x 6 in., cloth, $3.

The author's object has been to prepare a handy reference book for the amateur mechanic which would give processes that could be employed without elaborate equipment or great expense.

STEAM SHOVEL MINING.

Including a Consideration of Electric Shovels and other Power Excavators in Open-pit Mining. By Robert Marsh, Jr. First edition. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 258 pp., illus., tables, 9 x 6 in., cloth, $3.50.

The purpose of this volume is to present general information upon the development and study of those mining problems which may best be solved by open-pit methods involving the use of power excavators. A general knowledge of mining practise is assumed.

STRUCTURAL STEELWORK.

Relating Principally to the Construction of Steel-framed Buildings. By Ernest G. Beck. London and New York, Longmans, Green and Co., 1920. 462 pp., illus., tables, 9 x 6 in., cloth, $7.50.

This book presents information likely to be of use in the design and construction of ordinary steel-framed structures. The principal endeavor has been to be broadly suggestive, rather than particular or exhaustive, to propose common sense lines of argument based upon straightforward consideration of the facts, instead of attempting to generalize or formulate specific relations from details which cannot be more than typical. The work follows British practise, and is based upon a series of articles contributed to the Mechanical World.

SURVEYING.

By W. Norman Thomas. London, Edward Arnold, 1920. 537 pp., illus., plate, maps, tables, 9 x 6 in., cloth, $10.50. (Gift of Longmans, Green and Co.)

CONTENTS: Chain Surveying; Optics and Magnetism; Instruments; The Theodolite; Theodolite Surveying and Dialling; The Level and Levelling; Trigonometrical and Barometrical Levelling; Tacheometry and Rangefinding; Plane Table Surveying; Curve Ranging; Earthwork Calculations; Hydrographic Surveying; Triangulation; Base Line Measurement; Spherical Trigonometry; Astronomical Terms; Meridian, Longitude, Latitude and Time; Photographic Surveying; Appendix:—Errors in Surveying; Trigonometrical Formulas; Miscellaneous Examples.

The author of this treatise is Lecturer in civil engineering in the University of Birmingham, England, and the volume is an amplification of his lectures to students. It is intended as a textbook and a reference book for surveyors in practise. Calculus is used where necessary, and a special effort has been made to keep the investigation of errors before the readers' mind.

TECHNICAL GAS AND FUEL ANALYSIS.

By Alfred H. White. Second edition, revised and enlarged. N. Y. and London, McGraw-Hill Book Co., Inc., 1920. 319 pp., illus., tables, 8 x 6 in., cloth, $3.

The first edition of this work, which appeared in 1913, was intended to present the conclusions of the various committees of technical societies which had reported on the testing of fuels and their utilization. Since 1913 our knowledge of gas and fuel analysis has been distinctly increased. Standard methods for sampling and analyzing coal and coke and for examining liquid fuels have been adopted by several societies. Methods for gas analysis have been critically studied and new methods developed. These advances have been carefully reviewed for this edition, which is about 20 per cent larger than the former one.

TEXTBOOK OF AERO ENGINES.

By E. H. Sherbondy and G. Douglas Wardrop. N. Y., Frederick A. Stokes Co., copyright 1920. 363 pp., illus., diagrams, plates, 12 x 9 in., cloth, $10.

The present work is a review of the theory and practise of the design of engines for aerial navigation. The first part treats of theory and includes the theory of the cycle, the work available, the effect of altitude, pressure, etc., on the power, and the theory and design of compressors. The second part describes the current types of American, British, French, German and Italian engines. An appendix gives tables of use to designers. The book is fully illustrated with drawings and photographs.

UTILISATION DES VAPEURS D'ECHAPPEMENT DANS LES HOUILLERES.

en Vue de la Production d'Energie Electrique. By Adrien Barjou, preface by Maurice Soubrier. Paris, Gauthier-Villars et Cie, 1920. 90 pp., illus., 10 x 6 in., paper.

The author of this work discusses the utilization of exhaust steam in low-pressure turbines for the production of electricity or compressed air. The particular case studied is that of coal mines which have outgrown their power-plants and are faced with the necessity of extending them. The economic and technical results obtained with low-pressure turbines are set forth in this book.

VOCATIONAL ARITHMETIC.

By Clarence E. Paddock and Edward E. Holton. N. Y. and Lond., D. Appleton and Co., 1920. 232 pp., illus., tables, 7 x 5 in., cloth, $2.

This is an elementary arithmetic for vocational schools anp mechanics, in which the usual branches of arithmetic are treated in a simple way and accompanied by a large number of practical problems, carefully selected to present applications to sucq vocations as shopwork, carpentry, masonry, foundry work and excavation.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Atlanta.—July 29, 1920, Atlanta Gas & Electric Building. Business meeting. Election of officers as follows: Chairman, H. L. Wills; Vice-Chairman, H. E. Bussey; Secretary-Treasurer, J. M. Bradfield; Executive Committee, G. A. Iler, J. E. Mellett and Geo. K. Selden. Attendance 29.

August 26, 1920, Atlanta Gas & Electric Building. Business meeting. Attendance 23.

Cincinnati.—September 9, 1920, Assembly Hall, Union Gas & Elec. Company. The speaker of the evening was Mr. P. M. Lincoln, a Past-President of the Institute, who gave a very interesting talk on the history of the Institute, especially that part which refers to Sections. The second part of Mr. Lincoln's program was on the electrification of steam roads. He enumerated the different steam roads that had already been electrified, and gave figures proving how the electrification of steam roads would benefit the entire country. Attendance 53.

Denver.—August 19, 1920. Savoy Hotel. This special meeting was called in honor of Secretary Hutchinson, who visited Denver on his return trip from the Pacific Coast Convention. Mr. Hutchinson talked to the members about Institute affairs in general and particularly about some of the new features in organization which were under consideration. Mr. H. B. Dwight was called upon and told something of his experiences at the Annual Convention where he went as a representative of the Denver Section. Attendance 18.

Detroit-Ann Arbor.—August 23, 1920. Meeting of Executive Committee for the purpose of appointing various committees of the Section. Present: Messrs. Parker, Kittredge, Albright, Reyneau, Meyer, Cannon and Wise.

Spokane.—August 9, 1920, W. W. P. Co. Meeting of Executive Committee. Appointment of Mr. H. V. Carpenter as Vice-Chairman in place of Mr. Foster Russell, resigned. Appointment of Mr. Royer as Chairman of the Membership Committee and Mr. Henderson as Chairman of the Papers Committee Present: Messrs. Daniels, Fisken, Royer, Henderson, Pospisil.

Utah.—August 16, 1920, Commercial Club. Speaker: Mr. F. L. Hutchinson, Secretary of the Institute. Subject: "Institute Activities." Attendance 16.

Prior to the meeting a dinner was held for Mr. Hutchinson at the University Club, at which 12 members of the Section were present.

August 23, 1920, Commercial Club. Meeting of Executive Committee. Resignation of Mr. H. D. Randall as member of Executive Committee accepted and Mr. C. P. Kahler elected in his place. Mr. D. L. Brundige appointed Chairman of Program Committee. Secretary instructed to ask Board of Directors of Institute for extension of Section territory. Present: Messrs. Merrill, Ashworth, Brundige, Plumb and Talmage.

PAST BRANCH MEETING

University of California.—August 25, 1920. Talk on "Westinghouse Junior Courses" by Messrs. Andrews, Baston and Cates. Attendance 11.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before October 31, 1920.

EDISON MEDAL COMMITTEE

(Appointed by the President for terms of five years)

(Term expires July 31, 1921.)
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
(Term expires July 31, 1922.)
Comfort A. Adams, Chairman, L. A. Ferguson, S. W. Stratton.
(Term expires July 31, 1923.)
Frederick Bedell, L. T. Robinson, Calvert Townley.
(Term expires July 31, 1924.)
E. D. Adams, H. H. Barnes, B. G. Lamme.
(Term expires July 31, 1925.)
H. M. Byllesby, D. E. Drake, W. L. R. Emmet.

Elected by the Board of Directors from its own membership for terms of two years.

(Term expires July 31, 1921.)
G. Faccioli, W. A. Hall, Wilfred Sykes.
(Term expires July 31, 1922.)
L. E. Imlay, F. D. Newbury, W. I. Slichter.

Ex-Officio

A. W. Berresford, President, George A. Hamilton, Treasurer,
F. L. Hutchinson, Secretary.

SPECIAL COMMITTEES

GEOGRAPHICAL DIVISIONS AND ELECTION PROCEDURE

H. H. Barnes, Chairman, 120 Broadway, New York, N. Y.

Lightning Arrester Spark Gaps—II

BY CHESTER T. ALLCUTT
Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

This paper presents data giving the discharge characteristics of a commercial type of impulse gap under different conditions. Test data are also presented giving the characteristics of certain experimental gap structures designed to minimize the effects of adverse weather conditions, such as rain, fog, etc. A brief discussion of some of the factors that determine the degree of protection afforded by a lightning arrester spark gap is included in the paper. The term "protection factor" is defined and curves giving the protection factor of certain types of gap are presented.

IN a former paper presented before the American Institute of Electrical Engineers in June 1918,[1] the writer described a selective gap for lightning arresters and gave the results of a number of tests on an experimental form of such a gap. Since the presentation of that paper, this selective gap, now commonly known as the impulse gap, has gone into rather extensive commercial use and it is thought that some data concerning the electrical characteristics of the commercial form of gap might be of interest. The object of this paper is to present such data and to discuss some of the features upon which the protective value of the gap depends.

It is well-known that the danger to electrical apparatus due to line disturbances of steep wave-front may be all out of proportion to the actual voltage of the disturbances. This is because a voltage of high frequency or of steep wave-front does not distribute itself uniformly through an electrical winding, but tends to "pile up" on the end turns of the winding and thus greatly endanger the insulation between turns. Due to its high electrostatic capacity the electrolytic lightning arrester is particularly well adapted to discharge high-frequency disturbances. Unfortunately, the electrolytic arrester must be connected to a line through a spark gap, as permanent connection to the line will result in over-heating and ultimate destruction of the arrester. It is necessary that the spark gap which connects the arrester to the line be so adjusted that it will not discharge normal line voltage. It is highly desirable, however, that the spark gap should discharge high-frequency disturbances at the lowest possible voltage in order to obtain a high degree of protection against such dangerous disturbances. The value of the impulse gap lies in the fact that it is selective in its action, that is, it will discharge a high-frequency disturbance at a voltage considerably less than its 60-cycle discharge voltage. By means of this gap, an electrolytic arrester may be isolated from the line under normal conditions and yet is automatically connected to the line upon the occurrence of a high-frequency impulse even if the magnitude of this impulse is less than the 60-cycle setting of the gap.

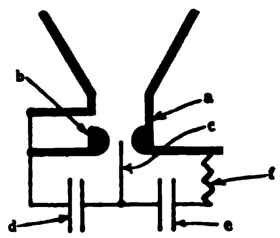

FIG. 1—DIAGRAM OF IMPULSE GAP

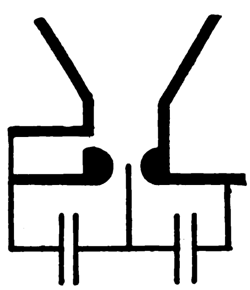

FIG. 2A—IMPULSE GAP ON 60 CYCLES

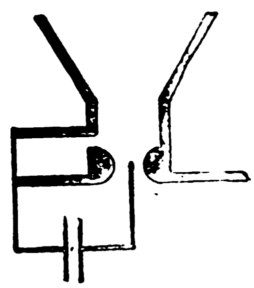

FIG. 2B—IMPULSE GAP WITH HIGH FREQUENCY APPLIED

Fig. 1 shows the electrical circuits involved in the simplest form of impulse gap. The gap proper consists of two sphere-horn electrodes *a* and *b*, which are connected respectively to the line and to an electrolytic arrester in the usual manner. In addition to these two main electrodes, an auxiliary electrode *c* is provided which is connected to one of the horns through a condenser *d* and to the other horn through a similar condenser *e* and a high resistance *f*. When a 60-cycle-

To be presented at the Chicago Meeting of the A. I. E. E. November 12, 1920.

1. C. T. Allcutt, "Lightning Arrester Spark Gaps." TRANSACTIONS, A. I. E. E., Volume XXXVII.

e. m. f. is applied across the gap the impedance of the resistance is negligible compared with that of the condensers, so the circuit is equivalent to that shown in Fig. 2A. In this figure, it will be seen that if the two condensers are equal, the potential of the auxiliary electrode will be half-way between the potentials of the two main electrodes. If the auxiliary electrode is placed half-way between the main electrodes, it will have practically no influence on the distribution on the electrostatic field between the two main electrodes, and consequently, the voltage required to produce a discharge across the gap will be substantially unaltered by the presence of the auxiliary electrode. If a high-frequency e. m. f., such as a line disturbance of steep wave-front, is impressed on the gap, conditions will be quite different from those existing when a 60-cycle e. m. f. is applied. In this latter case, the impedance offered by the resistance element is very much greater than the impedance of the condensers, so that the gap becomes very nearly equivalent to that shown in Fig. 2B. In this case it will be seen that if the capacity of the condenser is large compared with the capacity existing between the auxiliary electrode and the main electrode, practically the entire voltage will appear across half the gap, that is, between the auxiliary electrode and one of the main electrodes. A discharge across this half gap will immediately charge up the condenser to full voltage and a discharge across the other half of the gap will immediately follow. It becomes apparent from the foregoing that the discharge voltage of the gap should be much lower when a high-frequency e. m. f. is applied than when 60-cycle e. m. f. is applied. For example, if we assume that the separation between the main electrodes is, say, six cm., the gap will behave on a 60-cycle line in the same manner as an ordinary sphere horn gap having the same gap setting. When a high-frequency e. m. f. is applied to the gap, it will be very nearly equivalent to a needle gap having a setting of but three cm. As pointed out in the writer's former paper, it has actually been demonstrated by experiment that this construction does result in a much lower discharge voltage for high frequency than for 60 cycles.

Fig. 3 shows a standard 44,000-volt impulse gap. A rather exhaustive series of experiments was carried out on the gap shown in this photograph. The experiments involved tests on frequencies ranging from 60 cycles up to the highest frequencies that could be produced in the laboratory. Inasmuch as the other sizes of impulse gaps have characteristics very similar to those of the one shown, the writer is presenting here only the data obtained on this one size of gap, because the most complete series of tests was made on this size.

The gap shown in Fig. 3 differs somewhat from the experimental type described in the previous paper. The capacitances for maintaining the auxiliary electrode at the proper potentials are furnished by pin type insulators *a* and *b*. These insulators have an electrostatic capacity of approximately 2×10^{-11} farad. Due to the effect of capacity to ground, the auxiliary electrode is not maintained at a potential exactly half-way between the potentials of the main electrodes. It has been found by experiment that the proper position of the auxiliary electrode is such that its distance from the

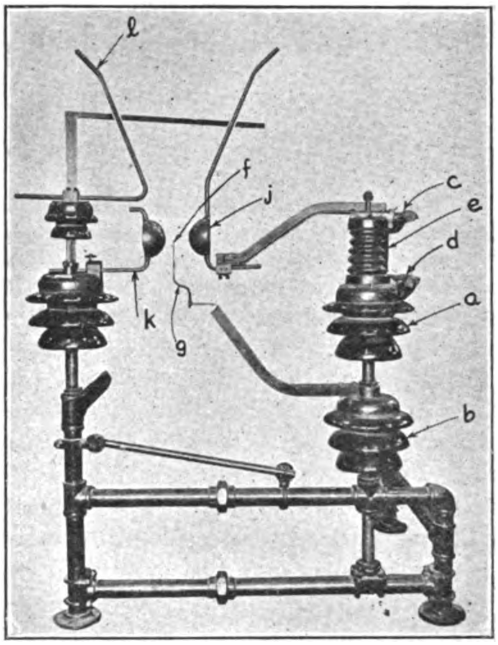

FIG. 3—44,000-VOLT IMPULSE GAP

sphere horn *m* is approximately six-tenths of the gap length. In this position it does not materially alter the 60-cycle discharge voltage of the gap. The unbalancing resistance is furnished by the resistors *c* and *d* which are enclosed in porcelain tubes mounted on the porcelain pillar *e*. These resistors have about 250,000

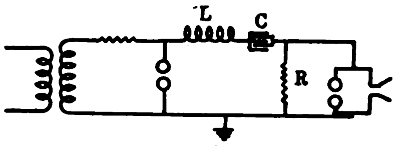

FIG. 4—IMPULSE GENERATOR CONNECTIONS

ohms resistance each and are of a special composition that retains its high resistivity under the most severe conditions of high voltage and high frequency. The resistors are about 30 cm. in length. The auxiliary electrode *f* is a pointed brass rod 0.08 in. (0.2 cm.) in diameter held in a ⅜-in. (0.95-cm.) diameter brass support member *g*, which is in turn mounted on an arm *h* of 1-in. angle iron. The hemispheres *j* mounted on horns are made of brass and are 12.5 cm. in diameter. In practise the charging resistance of the arrester is connected between the horn members *k* and *l*. For the purpose of test, *k* and *l* were connected and grounded to the frame of the gap structure.

The impulse discharge voltage of the gap was determined by a direct comparison with a 12.5-cm. sphere gap connected in parallel with it. The high-tension electrodes of the gap under test and of the sphere gap

were connected by a straight lead and the connection to the impulse generator was brought out from the middle point of this lead. The impulse generator itself was connected as shown in Fig. 4. The following cir-

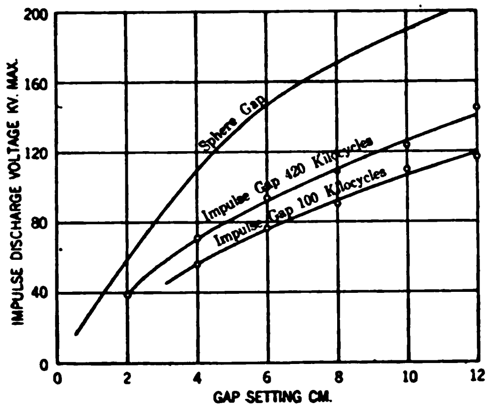

FIG. 5—IMPULSE DISCHARGE CHARACTERISTICS OF IMPULSE GAP COMPARED WITH SPHERE GAP

cuit constants were employed, giving very nearly critically damped impulse voltages.

For 100 kilocycle impulse:

$C = 5 \times 10^{-9}$ farad

$L = 1.25 \times 10^{-3}$ henry

$R = 1{,}000$ ohms.

For 420 kilocycles impulse:

$C = 5 \times 10^{-9}$ farad

$L = 8.3 \times 10^{-5}$ henry

$R = 320$ ohms

The condenser employed consisted of a stack of 100 impregnated paper condensers connected in series. Each condenser had a capacity of 0.5 microfarad. Single-layer inductances and water-tube resistors were

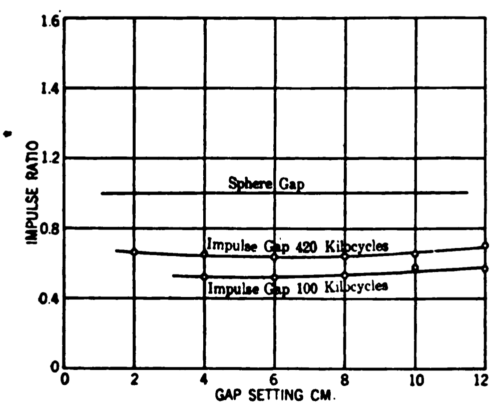

FIG. 6—IMPULSE RATIO OF IMPULSE GAP COMPARED WITH SPHERE GAP

used to complete the oscillating circuit. The test methods were identical with those outlined in the writer's previous paper.

Fig. 5 shows the impulse discharge voltage of the impulse gap plotted as a function of the gap setting. For purpose of comparison, a curve giving the impulse discharge voltage of a sphere gap is also shown. This curve also represents the 60-cycle discharge voltage of the impulse gap. The ratio between the impulse discharge voltage of a gap and its 60-cycle discharge voltage has been termed the "impulse ratio" by Mr. F.W. Peek.[2] The curves given in Fig. 6 show the impulse ratios of the impulse gap and of a simple sphere gap.

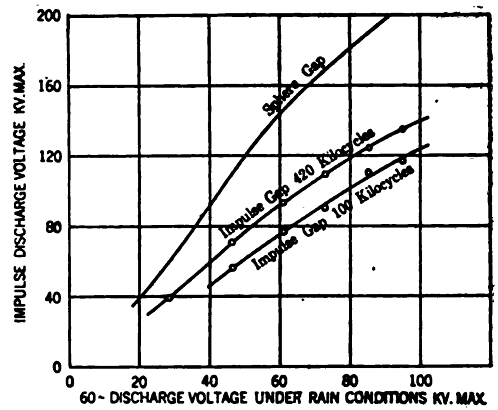

FIG. 7—IMPULSE DISCHARGE—THE 60-CYCLE DISCHARGE

When a lightning arrester spark gap is placed out of doors, the impulse ratio is not the proper criterion of the protective value of the gap. The spark gap must be so adjusted that it will withstand normal line voltage under the most unfavorable conditions. The gap setting necessary in service is, therefore, determined by the 60-cycle discharge voltage under rain conditions, since, in general, the 60-cycle discharge voltage of a gap is considerably reduced by moisture on the surface

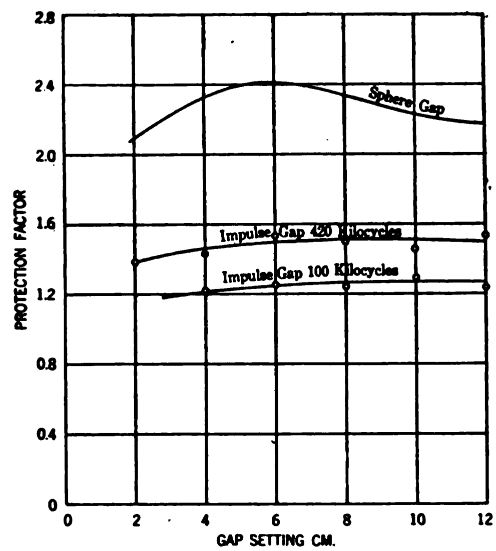

FIG. 8—PROTECTION FACTOR OF IMPULSE GAP COMPARED WITH SPHERE GAP

of the electrodes, such as is caused by rain or fog. The impulse discharge voltage, on the other hand, is practically unaffected by rainfall. The degree of protection against high-frequency disturbances afforded by the gap therefore depends on the ratio of the impulse discharge

2. F. W. Peek, Jr., "The Effect of Transient Voltages on Dielectrics." TRANS. A. I. E. E., Vol. XXXIV, 1915.

voltage of the gap to the 60-cycle discharge voltage *under rain conditions*. The term "protection factor" has been proposed for this ratio.[3] For a spark gap located indoors or otherwise completely protected from the weather, the protection factor will be the same as the impulse ratio.

Fig. 7 shows the impulse discharge voltage of the impulse gap plotted as a function of the 60-cycle discharge voltage under rain conditions, while Fig. 8 gives the protection factor as a function of gap setting. A comparison of Figs. 6 and 8 shows that the degree of protection afforded by a gap is considerably lessened where the gap is exposed to rain or dew. It is at once apparent that it would be highly desirable to provide some means for protecting a lightning arrester gap from the objectionable effects of adverse weather conditions without going to the great expense of constructing a shelter sufficiently large to cover the entire horn gap structure.

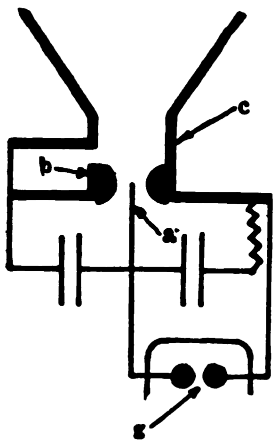

Fig. 9—Protected Impulse Gap

In a recent paper presented before the Institute[4], Mr. F. W. Peek described a very ingenious structure designed to obviate the difficulties due to rainfall without the necessity of providing a shelter over the arc-breaking horns of the gap. This "double balanced sphere gap," as Mr. Peek called his structure, consists of two sphere gaps in series. One of these gaps is sheltered from the weather and the design is such that the discharge voltage of the two gaps in series is determined largely by the discharge voltage of this sheltered gap. The arc-breaking horns are located outside the shelter. For a better description, reference is made to Mr. Peek's paper.

In his discussion of Mr. Peek's paper, the writer described a form of protected impulse gap that had previously been experimented with. This protected impulse gap is shown diagrammatically in Fig. 9. The gap structure shown in Fig. 3 was used for the main gap and a 6.25-cm. sphere gap g was connected between the auxiliary electrode and one of the main electrodes. The sphere gap g, shunting one-half of the main gap, may be sheltered from the weather

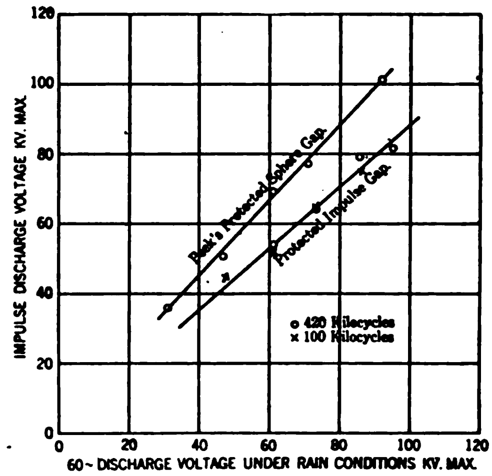

Fig. 10—Discharge Characteristics of Protected Gaps

while the main gap is exposed. The gap g is so set that it will discharge when the total voltage applied to the main gap equals the discharge voltage of the main gap under rain conditions. A discharge across g is followed immediately by a discharge between the auxiliary electrode a and the horn b. If g is so sheltered that its discharge voltage is independent of weather conditions, then the discharge voltage of the gap, as a whole, will also be substantially the same under all weather conditions. After a discharge has started across g and between a and b as described above, the rising arc quickly transfers from the auxiliary electrode a to the horn c, short-circuiting out the arc

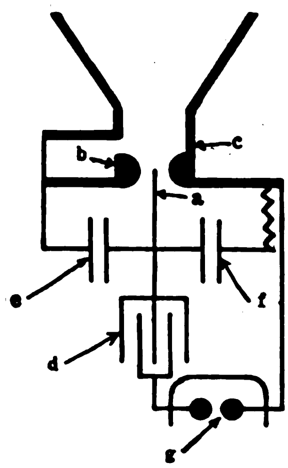

Fig. 11—Protected Impulse Gap

across g and effectively extinguishing it. This construction has been found to secure a very quick and effective suppression of the arc across g, thus permitting the use of a relatively small shelter.

4. F. W. Peek, Jr., "The Effect of Transient Voltages on Dielectrics—II." Proc. A. I. E. E., May 1919.

Fig. 10 gives the impulse discharge voltage of Mr. Peek's double balanced sphere gap in comparison with the protected impulse gap described above. It is assumed in these curves that the shelter over the protected gap keeps the electrodes dry under all conditions. In the present state of development, however, there is some doubt as to the efficacy of these protected gap structures. It has been found that merely wetting the surfaces of the electrodes of a gap will reduce the discharge voltage to nearly as low a value as will actual rainfall. It is obvious that a shelter which merely protects a gap from direct rainfall does not necessarily prevent the formation of moisture on the electrodes in damp or foggy weather, and, unless the electrodes are kept dry under all conditions, the purpose of the shelter will be defeated.

Another form of protected impulse gap that has been experimented with by the writer is shown in Fig. 11. In this case, the gap g, shunting one-half the main gap, is in series with a condenser d that is of somewhat higher capacity than the condensers e and f. In this case, a discharge across g will throw a relatively large capacity in shunt with the gap between a and c so

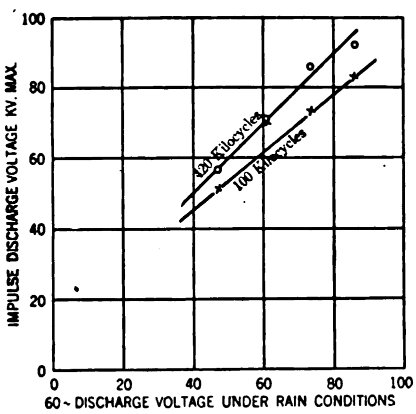

FIG. 12—PROTECTED IMPULSE GAP
See Fig. 11.

that most of the voltage will appear between a and b. A discharge between a and b is, of course, immediately followed by a discharge between a and c and a free discharge of the disturbances is permitted between the main electrodes b and c. In this case, no current flows across the gap g except the charging current of the condenser d. The discharge across g is only a fine "pin spark" so that it may be found possible to enclose g in a hermetically sealed chamber of small dimensions containing dry air. A gap of this character should be entirely independent of weather conditions. Fig. 12 gives the discharge characteristics of this form of protected gap. In obtaining the data for this curve, the main gap structure shown in Fig. 2 was employed. One-half the gap was shunted by a 6.25-cm. sphere gap in series with a capacity of about 10^{-10} farad. At present, it is impossible to say whether a protected gap of this type will be commercially practicable. The writer hopes to have more information concerning the possibilities of this device available for presentation at some future date.

It will be noted that the test data presented in this paper give only the results of tests up to 420 kilocycles. Tests have been made in the laboratory at far higher frequencies, but it is not believed that these higher frequencies represent conditions that actually occur in a transmission line. In a recent paper presented before the Institute, Dr. C. P. Steinmetz[5] showed that an infinitely steep wave-front traveling along a transmission line will be reduced to a frequency of 1000 kilocycles after traveling about 300 yards. The 420-kilocycle wave-front used in these tests represents an infinitely steep wave after having traveled about one mile. Some curves showing the discharge characteristics of the impulse gap with extremely steep wave-fronts (3000 kilocycles) applied were presented by the writer in his discussion of Mr. Peek's recent paper. These 3000-kilocycle tests, however, represented conditions that could not occur in practise, as an infinitely steep wave-front would be reduced to a frequency lower than this in less than 100 feet.

Life and Performance Tests of O F Lightning Arresters

BY N. A. LOUGEE
of the General Electric Co.

I—LIFE RUN TESTS OF *O F* ARRESTERS

SINCE the first papers on the oxide film (*O F*) lightning arrester were given a little over two years ago,[1] the arrester has proved itself to be a worthy piece of apparatus by performance in regular

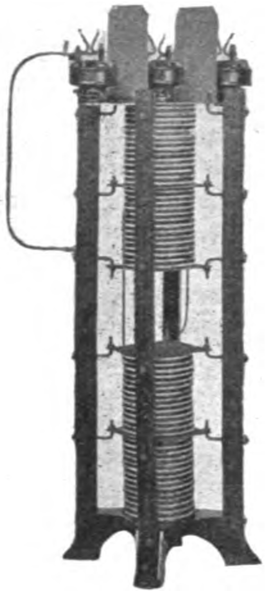

Fig. 1—Oxide Film Lightning Arrester for Indoor Service on Three-Phase Circuits, 5000-7500 Volts

service. Several hundred arresters up to 73-kv. rating, are now installed on both indoor and outdoor

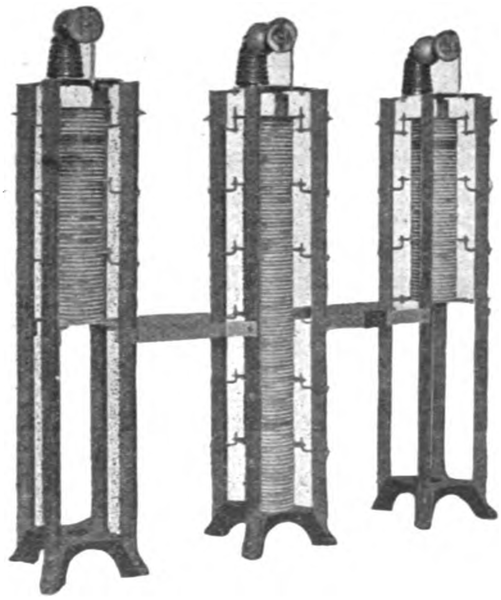

Fig. 2—Oxide Film Lightning Arrester for Indoor Service on Three-Phase Circuits, 15000-25,000 Volts

circuits, and higher voltage units will soon be in service. Figs. 1, 2, 3 and 4 show the typical designs used.

1. *The O F Lightning Arrester*, Trans., A. I. E. E., Vol. XXXVII, 1918.

To be presented at the Chicago Meeting of the A. I. E. E., November 12, 1920.

In Fig. 1, the three phase legs and the ground leg are all arranged in one stack, the bottom section being the ground leg. In Fig. 2, the three phase legs are the

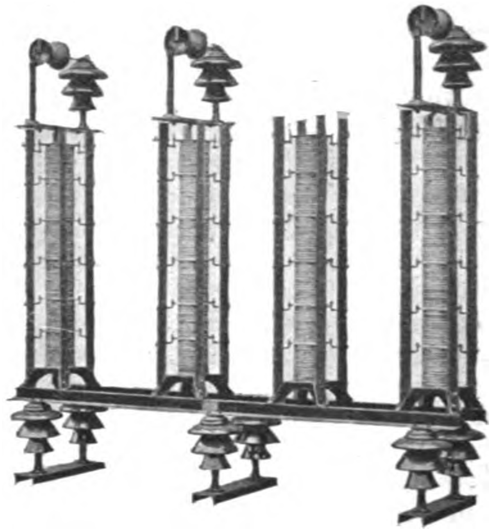

Fig. 3—Oxide Film Lightning Arrester for Indoor Service on Three-Phase Circuits, 37,000-50,000 Volts

upper sections and the ground leg is the lower section. In Figs. 3 and 4, the three phase legs and ground leg are set up parallel to one another. Fig. 5 shows the covered sphere gap used with the outdoor design, which permits of an indoor setting. Due to the small leakage current of these arresters (about 0.010 ampere),

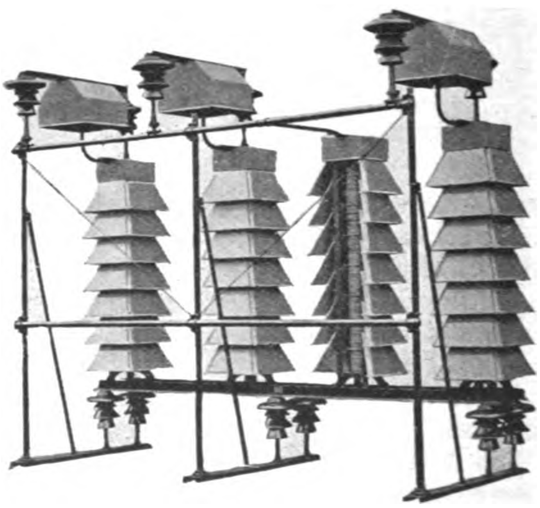

Fig. 4—Oxide Film Lightning Arrester for Outdoor Service on Three-Phase Circuits, 50,000-73,000 Volts.—Ground Stack Shields Removed for Cell Inspection and Test

it is not necessary to use horn gaps to aid in breaking the arc, and it is, therefore, possible to use the covered sphere gap which has previously been described in the proceedings of the Institute.[2] Fig. 6 shows the

2. *The Effect of Transient Voltages on Dielectrics—II*, F. W. Peek, Jr., Trans., A. I. E. E., Vol. XXXVIII.

testing device used and its method of operation, about which more will be said a little later.

The life of a lightning arrester is a very important factor, and one that has to be estimated from both operating and laboratory data. Operating data obtained during the past five years show that little deterioration has occurred to the *O F* cells. Cells have been returned from typical installations and tested and little, if any, change has been found.

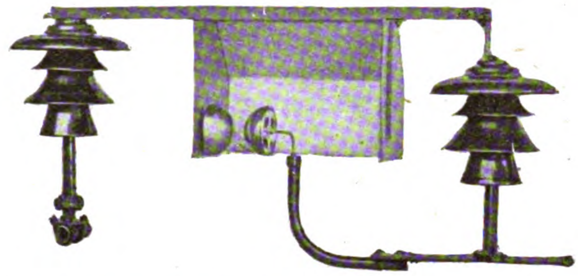

Fig. 5—Covered Hemisphere Gap as Used on Outdoor Type Oxide Film Arrester—50,000-73,000 Volts—Section of Cover Omitted to Show Gap

Fig. 7 is a view of an opened returned cell, and shows the film side of the electrodes and the porcelain spacer. The lead peroxide (PbO_2) filler has been removed. This cell was returned recently from a 13,000-volt arrester installed early in 1916, and which has been subjected to much more than average service, due to its location and surroundings. The few white spots in the illustration are discharge areas covered with yellow litharge (PbO). This PbO area or plug is what has caused the cell to reseal after the surge has passed through, and is reduced from the PbO_2 filler by the heat of the current through the small discharge spot in the film. The larger dark areas are where some

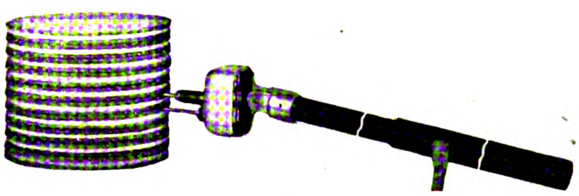

Fig. 6—Oxide Film Cell Testing Device in Position for Testing

of the PbO_2 filler is still adhering to other discharge areas, and the light background is the varnish film. The lead peroxide filler showed no change.

To obtain information on the life of *O F* arresters several years ahead of outside reports, however, an intensive test has been running during the past few years. Fig. 8 gives the general scheme of circuit used.

In Fig. 8, the surge circuit is shown to the right and consists of the usual inductance, capacitance and air gap, used to obtain oscillations. The 50,000-volt transformer charges the condensers, which, upon breaking down the air gap set for a little under 50,000 volts, cause the surge through the arresters. The transformer to the left supplies the dynamic 60-cycle voltage to all the arresters running on this particular voltage. Ordinarily all the lever switches are down (Fig. 8 shows only one particular voltage, one arrester and one set of switches. With this arrangement the arresters are separate from the

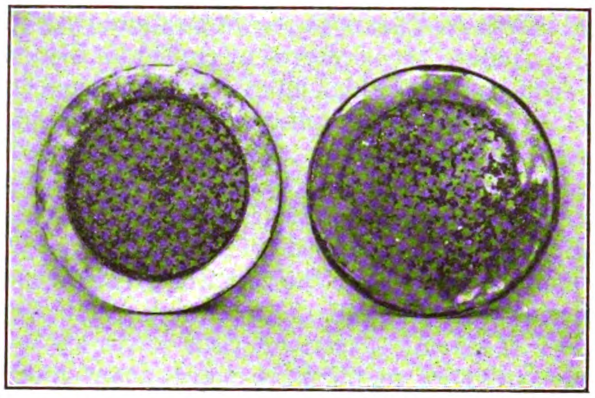

Fig. 7—Inside of Electrodes of *O F* Lightning Arrester Cell Returned From 13,000-Volt Installation After Four Years of Service

surge circuit. When it is desired to surge any one particular arrester, the upper lever switch corresponding to this arrester is thrown, thus paralleling the two transformers supplying dynamic voltage. The lower lever switch is then opened and this particular arrester is still on dynamic voltage, but also on the surge circuit which can now be thrown on. After surging, this arrester is thrown back on the regular dynamic transformer, and the next arrester put through a similar operation. This

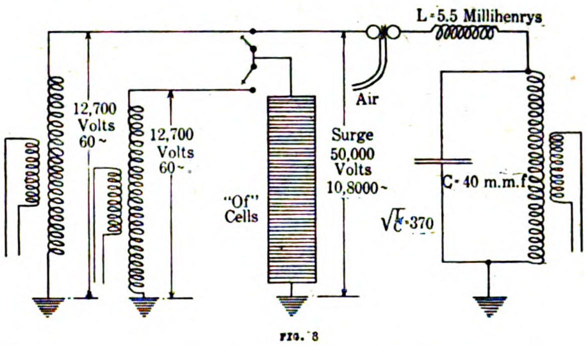

Fig. 8—Circuit Connection Used in Intensive Life Run Tests

arrangement of transformers and switches permits the regular dynamic voltage to all the arrester to be uninterrupted during surging operations.

O F arresters were placed on 330, 2300 and 12,700 volts respectively at 60 cycles with no series gap, and all arranged as shown in Fig. 8. These arresters have been surged daily, the surge current through the arresters having a maximum peak value of about 50 amperes and dying down to about 20 amperes at the end. This surge, having a surge impedance of 370 ohms is representative of an actual surge on a line, except that

the average actual surge has a higher frequency and may at times be more powerful. It has been found, however, that the lower the frequency of a surgé, the more difficult it is for an arrester to seal.

330-Volt Circuit—Single O F Cells.

These cells take from 5 to 75 milliamperes leakage current and run at a temperature of about 50 deg. cent. It took about four years to record a failure with these cells. A failure then occurred by enough of the PbO_2 being reduced to cause high internal resistance and hence loss of protection. The voltage across the cells being, of course, always the same, causes this group of cells to be more permanent than the 2300- and 12,700-volt arresters. With these latter arresters the voltage distribution across the various cells may change. This adds one more variable to the action of arresters consisting of more than one cell.

2300-Volt Circuit—Eight O F Cells in Series.

These arresters so far have acted about like the single cells; that is, voltage distribution has remained normal. Voltage distribution is obtained by means of shunting vacuum tubes, which break down or glow at various voltages, across each cell in turn. It is the same idea used to test the cells in service as shown in Fig. 6. For service conditions a vacuum tube which will glow at about 1000 volts a-c. is used. As the internal condition of a cell changes, and more particularly the film, the voltage drop when in series with a number of cells may change. Although this is not an infallible method of picking out poor cells in service, it does give a reliable indication in most cases. For voltage distribution tests, tubes breaking down between 100 and 2300 volts a-c. respectively are used. For convenience in interpolating these data, a cell having a voltage drop of less than 200 is designated low, from 200 to 400 is designated normal, from 400 to 600 is designated high, and above 600 is designated very high. The results can then be plotted against the respective cells by using a different color for each of the above four groups. The units on 2300 volts have shown with one or two exceptions only normal cells on voltage distribution, and the few low or high cells which have appeared from time to time, have returned again to normal. The leakage current of this group of arresters varies between 1 and 10 milliamperes, and the cells run at a temperature of about 40 deg. cent. A few units have failed or lost their protection after four years of continuous service.

12,700-Volt Circuit—Forty-seven O F Cells in Series.

These arresters have been running almost two years with no appreciable deterioration. To obtain the relative effect of dynamic and surge, similar arresters were run with different service characteristics, as follows: (a) dynamic only, (b) dynamic and surge, (c) surge only and (d) idle. The leakage current is from 5 to 10 milliamperes and about the same through all the arresters. The temperature is about 35 deg. cent. at the top of the stack, 45 deg. cent. in the middle and 30 deg. cent. at the bottom of the stack. Results to date show that (a) and (b) types of arresters give about the same characteristics; that is, the daily surge has no ill effect on the arresters. Both (a) and (b) show a gradual tendency for low-voltage cells to appear at the bottom of the stack and higher voltage cells at the top. Here again no change has been found to be absolute; that is, unless a cell is extremely high, it may go from low to high and back again. The low cells at the bottom of a stack may be due to either capacity or temperature, but probably the latter, as all the cells are about normal when first put on the circuit. The (c) and (d) types of cells show a general scattering of high and low cells throughout the stack.

This sort of intensive test has been found extremely valuable in trying to determine ahead of time what might occur in service and also for determining the effect of changes. So far as applying to standard arresters in service, it seems fair to assume that if an arrester will stand, say four years, under such an intensive test, it will stand up several times four years in actual service. Of course, it is always possible that a more or less direct lightning stroke or a long arcing ground will destroy an arrester, so this conclusion should apply to normal average service. As yet the factor to use between test and actual service is not known, but should be when longer service results are available.

II — PERFORMANCE OF *O F* ARRESTERS

The efficiency of a lightning arrester is governed by four factors; namely, sensitiveness, current discharge capacity, reseal and life.

Sensitiveness. As most electrical apparatus is tested at twice normal voltage, an arrester should be able to begin discharging at about this voltage. This means a horn or sphere gap should not be set for over double voltage for best results.

To care for steep wave impulses the time lag of the arrester should be a minimum.

Current Discharge Capacity. To discharge the energy from a surge, the discharge path must be of a sufficiently low resistance to prevent the voltage drop being above the insulation strength of the apparatus connected to the line. Again since a double voltage test is given apparatus, the discharge capacity of an arrester is usually given at double rated voltage.

Reseal. Reseal is the act of cutting off the discharge path through the arrester when the voltage across the arrester has returned to normal. The quicker this can be accomplished the better it will be, for if an arrester has sufficient discharge capacity, dynamic or line frequency current following, not only will be apt to destroy the arrester but may also cause bad disturbances on the line.

Reseal should also permit an arrester to be ready immediately for another discharge, for with a lightning storm over a large area of transmission lines, it is fair to assume that impulses and surges can occur extremely

close together; that is, at least a second apart, and sometimes several per second.

Life. It is difficult to define exactly what the life of a satisfactory arrester should be, but a good arrester should easily withstand the average surge or impulse. Arcing grounds are the most dangerous type of discharges and as they vary greatly in severity, depending upon the system and just where they occur, it is difficult to state how long an arrester should care for one.

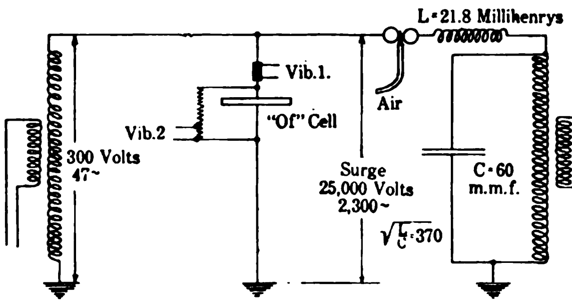

Fig. 9—Circuit Connection Used for Surge Tests

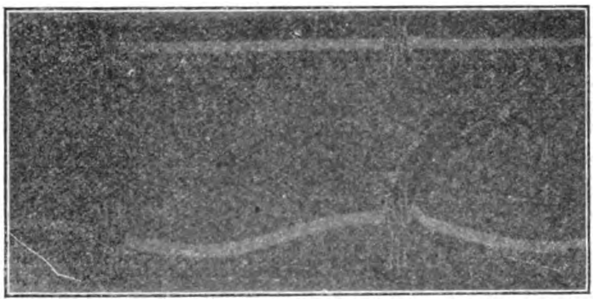

Fig. 10—*O F* Cell on Circuit in Fig. 9
Vibrator 1—Current through arrester, 1 mm. = 5 amperes (peak value)
Vibrator 2—Voltage across arrester, 1 mm. = 85 volts (peak value)

Tests. The following results are given to show how the *O F* arrester acts in regard to the above points. A single cell was used in all the following tests in order to obtain as powerful discharges through the cell as possible with the power available.

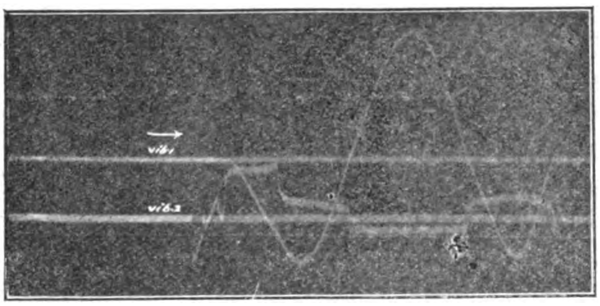

Fig. 11—*O F* Cell on a 600-Volt, 40-Cycle Circuit
Vibrator 1—Current through arrester, 1 mm. = 100 amperes.
Vibrator 2—Voltage across arrester, 1 mm. = 22 volts.

The first set of tests was made with a circuit as shown in Fig. 9. The usual surge circuit is used, which superimposes the 25,000-volt, 2300-cycle surge on the dynamic 300-volt, 47-cycle circuit. Fig. 10 shows an oscillogram of the discharge of an *O F* cell on this circuit. Vibrator 2 shows the dynamic 47-cycle voltage across the arrester with the 25,000-volt, 2300-cycle surge superimposed. The voltage peaks are kept at about double voltage and the cell reseals without permitting any dynamic current to follow; that is, this test shows that *reseal* and *sensitiveness* are satisfactory.

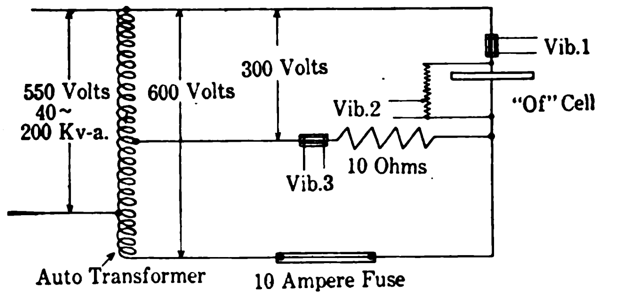

Fig. 12—Circuit Connection Used for Double-Voltage Surge Tests

Although the discharge through the cell is about 50 amperes, since the surge is supplied by a 15-kv-a. transformer, this test is not enough in itself to demonstrate that the discharge capacity is satisfactory.

Fig. 11 shows an oscillogram taken with 600 volts, 40 cycles (double standard voltage) impressed across an *O F* cell, to show current discharge capacity. The current peaks are 3500, 4200 and 3300 amperes respectively, and the voltage peaks 110, 89 and 154 volts respectively, giving an internal resistance of 0.031, 0.021 and 0.047 ohm respectively. Due to the low resistance of the *O F* cell and its relative value to the impedance of the circuit, the impressed voltage of 600 was not sustained across the cell when the high current flowed. This *current discharge capacity* is extremely high and should be ample under all conditions. The internal resistance of a cell will vary between 0.01 and 0.1 ohm, depending upon the particular path through the cell the discharge happens to pick out.

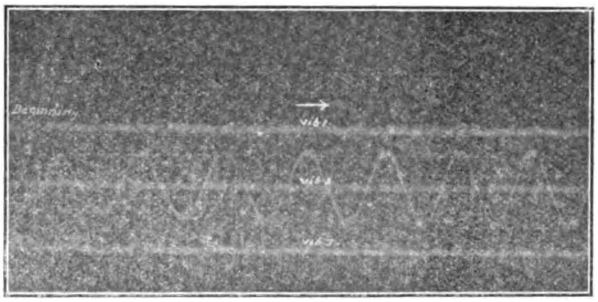

Fig. 13—*O F* Cell on Circuit in Fig. 12
Vibrator 1—Current through arrester at 600 volts, 1 mm. = 100 amperes
Vibrator 2—Voltage across arrester, 1 mm. = 22 volts.
Vibrator 3—Current through arrester at 300 volts, 1 mm. = 5 amperes.

Fig. 12 gives the connection used for a double voltage surge test with normal voltage immediately following. This is accomplished as shown by bringing out a tap from the transformer at 300 volts (standard volt-

age) and connecting it through a low resistance to the arrester cell. The resistance is necessary to prevent the lower section of the transformer from becoming short-circuited. With this connection, 600 volts are supplied to the arrester until the fuse opens, and the lower half of the transformer then being cut off, 300 volts are continued across the arrester cell. This is about the most severe test that can be given a lightning arrester and only an arrester which has a *low breakdown, good current discharge capacity* and *good sealing characteristics*, will act satisfactorily. Referring to the oscillogram taken on this circuit shown in Fig. 13, the switch impressing 600 volts across the cell closed at the extreme right. The cell immediately broke down and discharged 2700 amperes. This current after one-half cycle blew the 10-ampere fuse, thereby cutting off one-half of the transformer, and causing the voltage across the cell to drop to 300 or normal. There was then a sealing current of about 2 amperes for several cycles shown by vibrator 3, which caused the small breaks in the voltage wave. After a few seconds the current through the cell had dropped to normal or a few milliamperes.

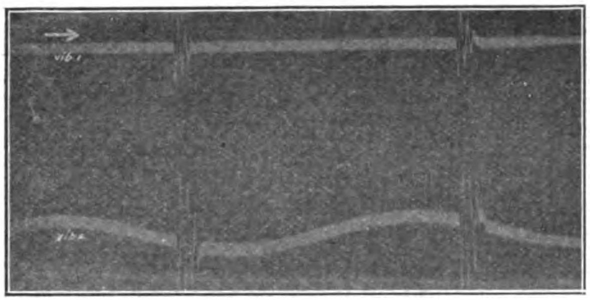

FIG. 14—*X* ARRESTER ON CIRCUIT IN FIG. 9

Vibrator 1—Current through arrester, 1 mm. = 5 amperes (peak value)
Vibrator 2—Voltage across arrester, 1 mm. = 85 volts (peak value).

To show the relation of protection and current discharge capacity, oscillograms were taken of single *O F* cells with external resistance in series on the ciruit shown in Fig. 9. *X* represents an arrester with a medium internal resistance and having a discharge capacity at double voltage of 60 amperes. *Y* represents an arrester with a higher internal resistance and having a discharge capacity of 20 amperes at double voltage.

Fig. 14 shows an oscillogram taken with arrester *X* and Fig. 15 an oscillogram taken with arrester *Y* on this circuit. It will be noted that the voltage peaks with *X* are 1600 and with *Y* 3650, as against 900 with the standard cell, which was shown in Fig. 10. Moreover if the frequency were nearer what is obtained in actual service, that is, from 10,000 to 100,000 cycles instead of 2300 cycles which had to be used for oscillographic work, this difference would have been much greater due to the higher impedance of the transformer at the higher frequencies. To give, therefore, satisfactory protection, an arrester must have a good current discharge capacity on double voltage and more than these *X* and *Y* arresters show. *X* and *Y* also show the bad effect of a poor ground connection.

The *life* of an *O F* arrester was discussed in Part I, Life Run Tests on *O F* Arresters, and is believed to be satisfactory.

Sensitiveness in service is limited by the gap setting, but since no dynamic current follows a surge discharge and the leakage current is only a few milliamperes, this gap setting can be small. The gap settings used in service correspond to line voltage, so the breakdown between phases is double voltage and the breakdown to ground is 1.7 times the voltage to ground. Since the covered gap is used for outdoor installations a dry or indoor setting can be used.

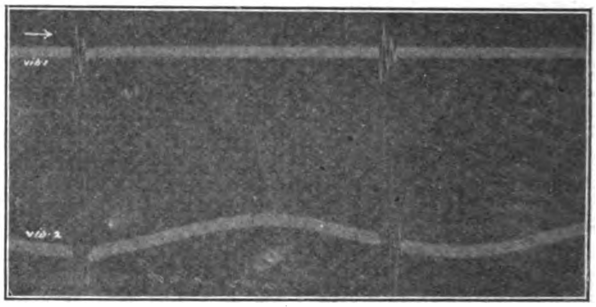

FIG. 15—*Y* ARRESTER ON CIRCUIT IN FIG. 9

Vibrator 2—Voltage across arrester, 1 mm. = 85 volts (peak value).

The author wishes to express his appreciation to Mr. E. E. Burger for his valuable assistance in obtaining the data used in this paper.

INVESTIGATIONS IN THE AUTOMOTIVE FIELD

Sometime ago, the Bureau of Standards commenced an investigation of the value of various systems of pre-heating the air-fuel mixtures used in automobile engines. A paper on this subject was presented at the June meeting of the Society of Automotive Engineers. Work has been continued and more complete data secured concerning the effect of different degrees of heating on engine economy, acceleration, etc. Several special fuels to be used in the airplane engine tests carried out in cooperation with McCook Field, have been analyzed as well as some blended fuels submitted for investigation by the Inventions Section of the War Department. Apparatus has been set up and test commenced to determine the performance of fan belts for the Motor Transport Corps. The apparatus consists of a motor driving a typical automobile cooling fan by means of a belt; the slippage can be determined by means of revolution counters attached to the motor and the fan pulley.

Surface Creepage and High-Voltage Insulation

BY T. NISHI

Tokyo Imperial University

1. Introduction

THE fundamental principle of designing high-voltage insulation, such as bushings, insulators etc., is obviously the application of electrostatics. A close examination of the evolution of the present methods of designing, however, will reveal the fact that it has been based very much upon experience rather than rational design. If the design were executed in rigorous accordance with the theory of electrostatics, the result would not necessarily be satisfactory, but very often lead to failure.

The main difficulty of high-voltage insulation design, as is well-known, is how to deal with the surface creepage, *e. g.*, discharge through the surface film of the dielectric; because the design of most insulators consists in the design of an air insulator rather than of an insulator of dielectrics, and the apparent dielectric strength of air just outside the dielectric is considerably lower than that in free space. Hence, in most cases of designing high-voltage insulation, the designers used to be confronted with this erratic phenomenon; the surface creepage, which stands outside the domain of any known electrical theories.

Sufficient information concerning the surface resistivity of a number of insulating materials is now available,[1] but the usefulness of such knowledge for the design of high-voltage insulation is rather limited, because the measurements of surface resistivity were made by low-voltage direct current and therefore the conditions of the measurement are far from the actual working conditions of high-voltage insulators, etc., where the surface is subject to intense field and very often surrounded by ionized air. As a natural consequence, the design had to be based upon practical experience, and sometimes would result in considerable unnecessary expenditure of money and labor.

From some experiments made in the Electrical Engineering Laboratory in Tokyo Imperial University and in the High-Voltage Laboratory of Leland Stanford Junior University, the author has found that the main cause of erratic surface creepage is the accumulation of free charge on the surface of (very probably also inside) the dielectric of which the bushings insulators etc. are made. The results of the experiments will be given below, though they are rather qualitative than quantitative owing to the extreme difficulty of exact measurement. The author hopes that these experiments may induce farther investigation on this subject with the result that the high-voltage insulation will be designed on a more scientific basis than at present.

1. *Bulletin, Bureau of Standards.* No. 234. June, 1914.

2. Accumulation of Free Charge on Dielectrics in Electric Field of High Intensity

(*I*) *Method of Measurement.*

The accumulated charge on the dielectric was measured by a ballistic galvanometer or a quadrant electrometer as shown in Fig. 1. The specimens were, in most cases, of the form of a slab. To measure the charge on the surface of a specimen, the slab was placed on a grounded metallic plate with the charged surface up. The metallic plane A (proof plane) which was earthed through the

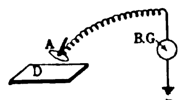

Fig. 1A

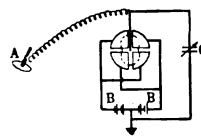

Fig. 1B

ballistic galvanometer BG, was suddenly placed on the spot of the dielectric where the charge was to be measured and at the same time the ballistic throw caused thereby was read. When the charge was too small and the sensitiveness of the galvanometer was insufficient for its measurement, the quadrant electrometer was used as shown in Fig. 1B, where B was the polarizing battery and C was an adjustable air condenser, through which the sensitiveness of the system could be changed at will.

(*II*) *Behavior of Dielectrics in Alternating Field.*

(*a*) *Under Spherical Electrode.* The specimen was placed between a spherical conductor 2.5 cm. in diameter (upper electrode) and a grounded metallic plate (lower electrode). In the first case, the specimen was in direct contact with the grounded plate, and the distance of the spherical elctrode from the upper surface of the dielectric was 10 cm. In the second case, the specimen was held just midway between the two electrodes. The distance of the electrodes from the opposing surfaces of the dielectric were 5 cm. each.

The alternating voltage was applied between the electrodes by a transformer, the primary voltage of which was regulated by means of an induction regulator. After applying the alternating e. m. f. for one minute, the field was taken away by opening the primary switch of the transformer or sometimes the voltage was gradually lowered to zero by turning the handle of the induction regulator. Immediately after taking away the field, the accumulated charge on the dielectric was measured by the method described in the preceding paragraph.

The dielectrics tested were paraffin wax, beeswax, ebonite, bakelite, glass, mica (crystaline), varnished cambric, oiled cloth, and mineral oil. They behaved,

however, in a similar manner, and, therefore, the typical results only are shown in Figs. 2, 3, 4 and 5.

The abscissas of these curves represent the effective values of the voltages applied between the electrodes, and the ordinates the ballistic throws of the galvanometer, or the deflections of the electrometer, that is to say, the accumulated charge in arbitrary units.

It will be noticed that, in every case, a negative

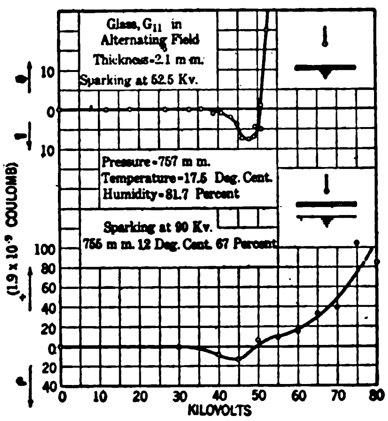

FIG. 2

charge appeared first at a certain intensity of the field and when the voltage was raised further, the charge changed its sign, *i. e.*, there appeared a positive charge, and finally a sparking discharge took place.

It is to be emphasized that, in the above experiments, the appearance of the free charge was found always to be accompanied by a corona discharge at the surface of the spherical electrode. The conclusion was drawn therefore, that the chief cause of producing

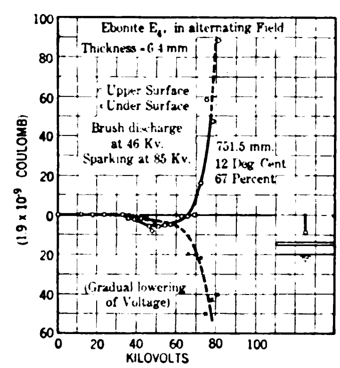

FIG. 3

the free charge is the action of the ions in air, and this fact is supported by other results which will be described in the following paragraphs.

The thickness of the dielectrics and the distance of the upper electrode seemed to have considerable effect on this phenomenon, but it was impossible for the author to touch upon this point owing to lack of time.

(*b*) *Under Needle Electrode*. The procedure in these experiments was the same in those referred to above, and the typical results are shown in Figs. 6, 7, 8, 9 and 10.

In this case, the charge appeared at far lower voltage than in the former case. Very probably such effect was mainly due to the fact that the corona started at lower voltage and not to the different distribution of electric field at the surface of the dielectrics.

The change of the sign of the accumulated charge does not take place at the same voltage throughout the whole surface of the dielectric, but the charge at

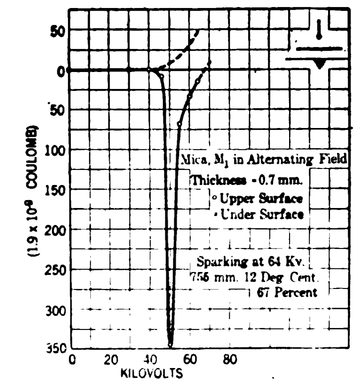

FIG. 4

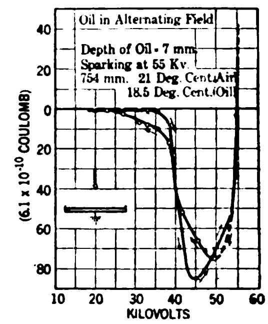

FIG. 5

the central part, *i. e.* just under the electrode changes its sign at a lower voltage than in the surrounding region. This fact was clearly demonstrated by the experiment where in a metallic plate of ring form was used in addition to the disk as proof plane. The specimen was subjected to an intense field for one minute, such field was then removed and immediately thereafter the disk was placed on the surface just under the needle point and the ring was placed con-

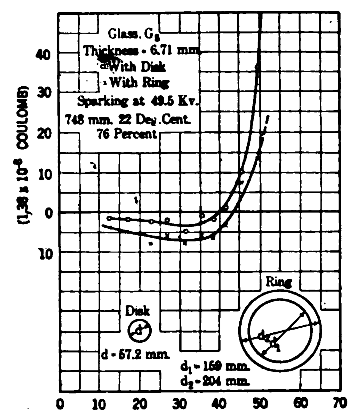

FIG. 6

centrically therewith. The results obtained by this procedure are shown in Fig. 6, 7 and 8. The question whether such effect is due to the special distribution of positive and negative ions in the discharge from the electrode, or due to merely the difference in intensity of the field on the surface of the dielectric, can not be answered at present owing to lack of experimental results.

When the voltage was gradually lowered, the

accumulation of free charge was far less than when it was taken away by opening the primary switch of the transformer, as shown in Fig. 7, 8, 9 and 10. This cannot be accounted for merely by the leakage in ordinary sense, because this tendency is most remarkable in paraffin wax, which has much higher volume and surface resistivity than other dielectrics.

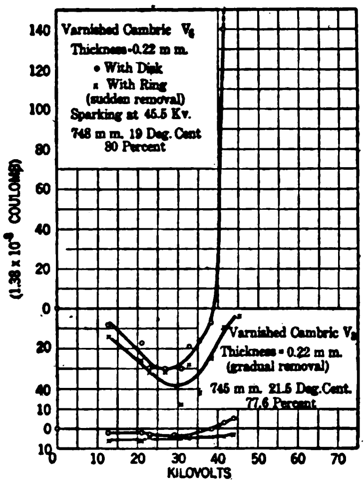

Fig. 7

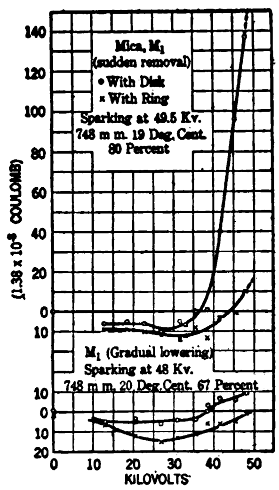

Fig. 8

At present, however, sufficient evidence has not been obtained to suggest an explanation for the above results though the author is inclined to believe that the accumulated charge is neutralized by the ions in air while the voltage is gradually lowered.

(c) *Between Disk and Plate Electrodes.* The specimen was placed between a brass disk 15 cm. in diameter and a grounded metallic plate so as to test the dielectric strength of the specimen. In this case, the charge accumulated on the surface around the disk was measured by means of ring-formed proof plane immediately after the electric field had been gradually taken away and the disk had been removed.

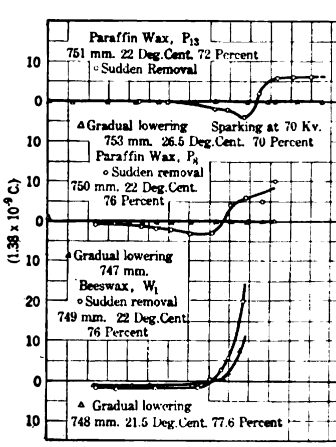

Fig. 9

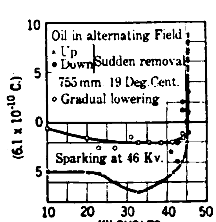

Fig. 10

The results are materially of the same nature as in the above cases and are shown in Fig. 11.

Certainly the observed values of the accumulated charge differ to a great extent from those while the field is on, because, in such an arrangement of the electrodes as used here, the leakage of the accumulated charge would be far greater than in the case where the upper electrode is not in contact with the surface of the specimen. It follows that these results are of comparatively minute value for differentiating the properties of one dielectric from the others. Nevertheless it is worth remarking that the observed values

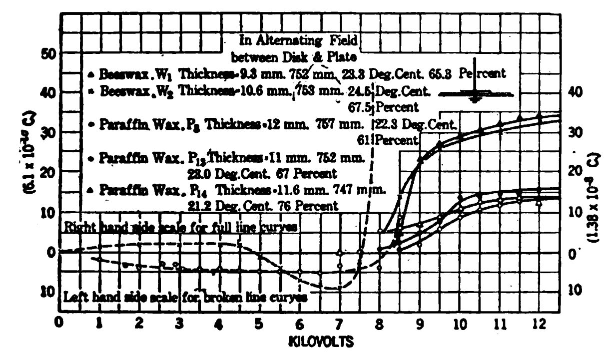

Fig. 11

of the accumulated charges for different specimens of the same material fall in near each other as shown in Fig. 11. And furthermore the result is instructive for illustrating the process of creeping discharge through the surface of the dielectric, which will take place if the applied voltage is high enough and the dielectric slab is not very wide.

Throughout the above experiments in three cases, it appeared that high dielectric constant was one of the favorable conditions for the accumulation of free charge on the surface of dielectrics, though the author is inclined to believe that the property of the materials relating to this phenomenon is of different nature from that we call dielectric constant, but may be something related to the photoelectric property of the materials.

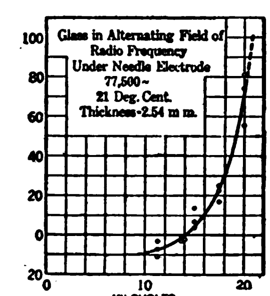

Fig. 12

(d) *Under Needle Electrode in Alternating Field of Radio Frequency.* This part of the research was carried out in the high-voltage laboratory at Stanford University by Professor Harris J. Ryan and the author.

The arrangement of the electrodes and the procedure of the experiment were the same as in (II) (b) except that the time of electrification was shorter, viz. 30 seconds. The result is shown in Fig. 12. The radio frequency field of high intensity was produced by a Poulsen arc-generator. We could not obtain the curve for wide range of the voltage owing to the unsteadiness of the arc, but the general characteristic can be conceived from the curve. It is very interesting or rather surprising to find that the dielectric behaves

in almost the same way in radio frequency field as in 50-cycle field. Also it may readily be noted that the positive charge appeared at a far lower voltage than when the dielectric was placed in 50-cycle field.

The author can hardly give a satisfactory explanation for the observed difference. Very probably it is mainly due to the difference in the amount and the behavior of ions in the two alternating fields of different frequency.

Anyhow the result is extremely valuable as the clew

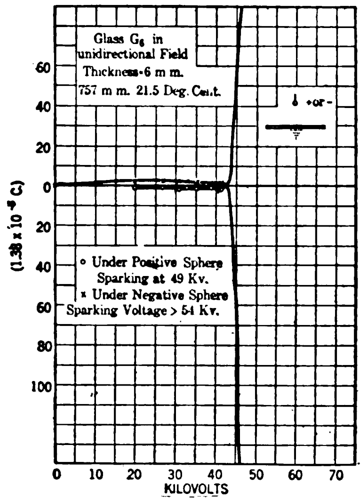

Fig. 13

for disclosing the secret in the dielectric phenomena and further study in this line is most desirable.

After this experiment had been made, the author found that some experiments on the behavior of dielectrics under the action of radio frequency point discharge had been carried out about twenty years ago by Knoblauch.[2] He used a Tesla coil and showed the accumulated charge on the surface of dielectrics by means of Lichtenberg's dust-figure.

According to his view, the above results may be accounted for as follows: The discharge from a pont electrode is of cone form, near the axis of which there are copious positive ions, while the negative ions are surrounding the former in the form of mantle. While the voltage is low, the negative ions predominate over the positive, and as the voltage is raised, the positive ions increase in number and can reach further and further. As a result, the accumulated charge changes its sign at a certain voltage and the area of positive region spreads over the surface as the voltage is raised further.

Though his theory is based upon several experimental facts and very excellent for the explanation in simple cases, the phenomena are too complicated and cannot be explained by such a simple theory in some cases which will be described later.

(III) Behavior of Dielectrics in Unidirectional Field.

(a) Under Spherical Electrode. The arrangement of the electrodes and the procedure of the experiment were the same as in the case of alternating field. To produce unidirectional field of high intensity, we used the combination of a transformer and a kenotron or in some cases a mechanical rectifier. The applied voltage between the electrodes was smoothed out by means of condensers, inductances and high resistance, and the field was not absolutely steady, but somewhat pulsating.

The typical results are shown in Fig. 13 and 14. It is noticeable that the charge appearing on the upper surface is of opposite sign to that of the upper electrode while the voltage is comparatively low, whereas the charge changes its sign abruptly at a certain value of the applied voltage, and if the voltage is further raised, the accumulation of the charge would rapidly increase as shown in these curves.

In the author's opinion, the charge which appears at comparatively weak field is of the same nature as ordinary residual charge as is observed in absorbing condensers, while at high intensity of the field, the charge is caused to appear by the ions in air. The ions in air, if produced, would accumulate themselves on the surface of the medium of higher dielectric constant. Furthermore the author suggests, though not supported by any definite experimental evidence, that there would be going on the process similar to the ionization of gas, that is to say, the charge may be produced by the bombardment of the ions under high electric force. Though not very definitely observed, the change of sign of the accumulated charge appeared

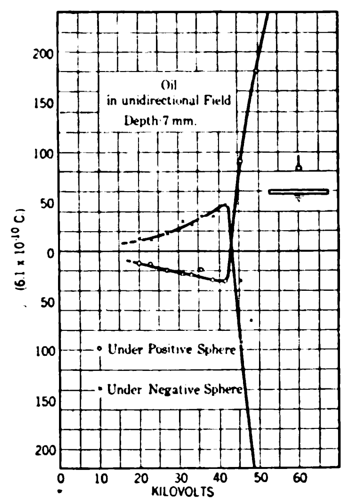

Fig. 14

to take place when the corona started on the surface of the sphere.

(b) In Uniform Field Practically Free from Ions. To ascertain the fact that the electrification of the dielectric when unaffected by the ions in air has the opposite sign to that of the electrode facing its surface, the specimens were tested, being placed midway between two large disk electrodes, the edges of which were rounded off with large radius as shown in Fig. 15. In such an arrangement of electrodes, it would be

2. *Ann. d. Phys.* 6 p. 353. 1901.

safely assumed that the ions in air are very few even when the potential difference between the electrodes is of comparatively high value. The author regrets that he could not apply the high-voltage source so as to make the middle point between the electrodes at zero potential, but was obliged to ground one of the electrodes because of the construction of the mechanical rectifier used.

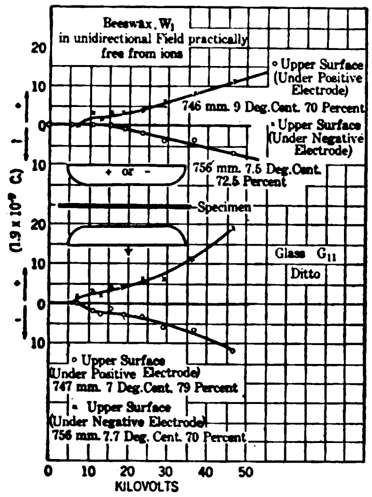

Fig. 15

The typical results are shown in Fig. 15. As had been expected, the accumulated charge on the top surface is of the opposite sign to that of the upper electrode.

The above results are very significant, because the phenomenon is in intimate connection with dielectric

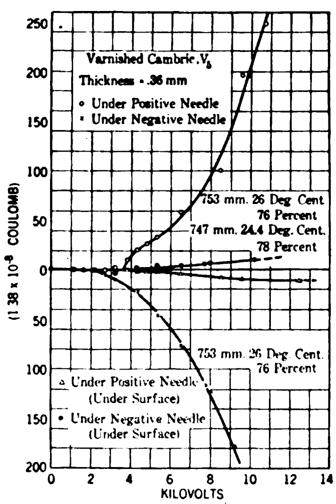

Fig. 16

absorption which is a long-disputed problem among physicists and electrical engineers.

We can account for the charge appearing in this case in two different ways. One of them is to suppose that the polarization of the dielectric remains after the field is off, and the other is to suppose that the ions in the dielectric were moved under electric force so as to accumulate near the surfaces and they could not recombine owing to their very low mobility in the solid dielectric after the field had been taken away. Which of them is correct is the most important determination of all dielectric problems and at present any definite answer cannot be given to the question owing to the scarcity of experimental data, though the author is inclined to believe the latter theory.

(c) *Under Needle Electrode.* The procedure of the experiment was the same as in the case of alternating

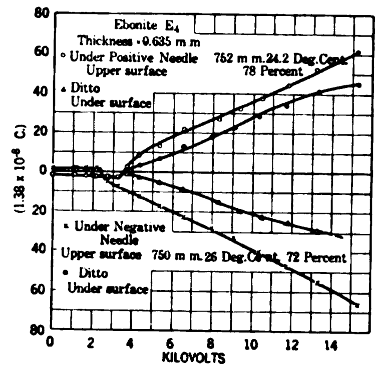

Fig. 17

field, and the typical results are shown in Fig. 16, 17 and 18.

In this case, the charge on the upper surface has always the same sign as the needle electrode. Very probably the charge observed in the above experiment (III) (b) is entirely masked by the charge due to the ions in air because of the copious ion supply at the needle point.

It is also noticeable that the charge appears at a lower voltage when the needle is negative than when

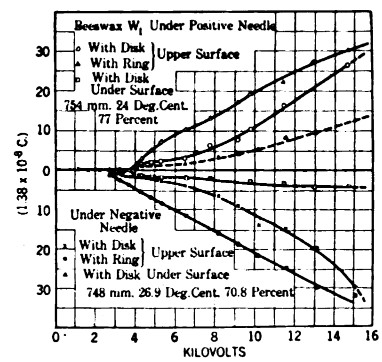

Fig. 18

it is positive. This may be accounted for by the fact that the voltage required to start corona is lower when the needle is negative than when it is positive. And this is one of the evidences to support the theory that the charge on the surface of the dielectric is produced by the action of the ions in air.

This theory is also supported by the results shown in Fig. 18, where the charge was measured with two different proof planes, disk and ring-formed, as in the

case of alternating field with needle electrode. Notwithstanding the difference in electric intensity where they are placed, the charges appeared at the same voltage as shown in Fig. 18. This shows that the presence of ions is one of the necessary conditions for the accumulation of free charge on the dielectric in intense field. It is also conceivable that the normal component of electric intensity is essential to the production of free charge on the dielectric, if the ions in air are the principal cause of the effect.

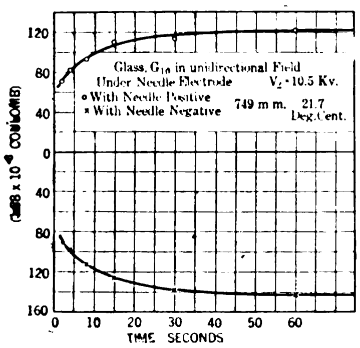

Fig. 19

(*d*) *Effect of Time on the Accumulation of Charge.* Time is no doubt one of the important factors affecting the amount of the accumulation of charge on the dielectric. The author made some experiments on the effect of time on the accumulation of charge when the dielectric were placed under the needle point electrode; the results being shown in Fig. 19, 20 and 21. In these curves, the abscissas represent the time in seconds during which the specimen had been subjected to the electric field, and the ordinates the ballistic throws of the galvanometer when the proof plane was placed

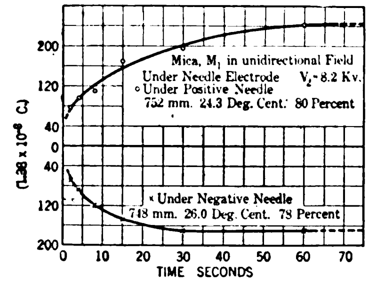

Fig. 20

on the dielectric surface immediately after the field had been taken away. It seems that the resistivity (especially surface resistivity) of the material is the main factor for giving the characteristic form of the curves.

In alternating field, the effect of time is very peculiar especially when the field is of such a value that the accumulated charge just changes its sign from negative to positive. It seems that it takes a certain time to change the condition of the surface so that the positive charge makes its appearance, as shown in Fig. 2.2

(*e*) *Effect of Surface Condition.* From the above experimental results it is conceivable that the free charge is accumulated on the dielectric through the direct action of the field and also the action of the ions in air, and the latter effect will predominate over the former when there is sufficient supply of ions, that is to say, when corona starts at some point in the field and the access to the dielectric is allowed for the ions. Hence, in the latter case, the condition of surface would affect the accumulation of free charge. The experiments in this line, however, cannot give confirmatory results on account of the inaccuracy of the measurement and the great difficulty in eliminating the other disturbing effects.

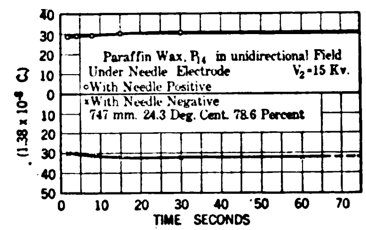

Fig. 21

The only remarkable result which could be definitely observed, is the effect of paraffin wax. When a glass slab was covered with a thin layer of paraffin wax, the accumulation of charge was reduced to a considerable extent, while shellac varnish had practically no effect, as shown in Figs. 23 and 24. The author could not find any remarkable difference in the accumulating charge between smooth and matt surfaces of the same beeswax specimen.

(*f*) *Decay of Accumulated Charge.* It is obvious that the accumulated charge on the dielectric in an intense field will finally disappear after the field is

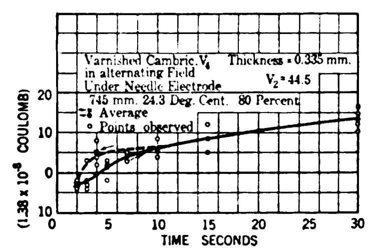

Fig. 22

taken away, but the rate of decay is different to a great extent for the various materials. For example, the charge in oil disappears in a few seconds so that the measured quantity would be far less than that when the field is acting. Very probably this is because of the greater mobility of ions in oil than in solid dielectrics. In glass, mica, varnished cloth and bakelite, the charge will entirely disappear in half an hour or an hour. In these cases, the surface leakage would be an important factor in causing the decay of charge. In paraffin wax, on the other hand, the accumulated charge will not disappear in a short time. It was observed that two months after electrification in electric

field, we had a certain amount of charge on the wax even when the slab had been covered on both sides with tin foils which had been perfectly grounded. Because of this fact, we were obliged to prepare many specimens to test the properties of the wax in its neutral state.

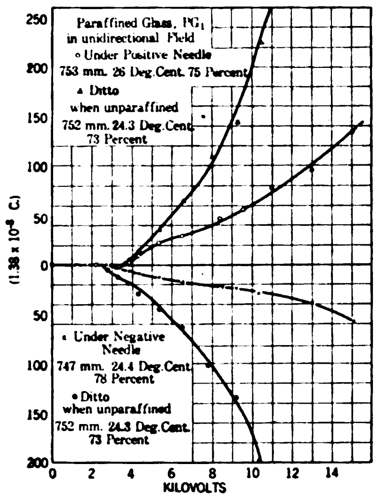

FIG. 23

It is regretted that there was not time enough to make any quantitative measurement on the decay of accumulated charge, though the author made some observations on the current leaking from the dielectric after it had been heavily electrified in an intense field under needle electrode. The curves shown in Fig. 25 are typical ones.

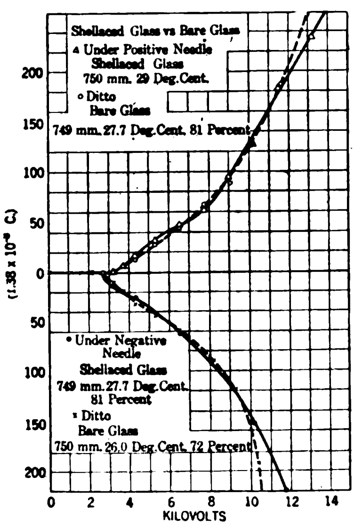

FIG. 24

(*IV*) *Behavior of Porcelain Bushings in Actual Use.* Now it is very important to test the dielectric when it is in actual use as high-voltage insulation. In the high-voltage laboratory of Tokyo Imperial University, we have a 500-kv. testing transformer made by Shibaura Engineering Works. Its bushing was, however, supplied by General Electric Company. This bushing is of the oil-filled type and its outer shell is made of porcelain. A skeleton drawing of it is shown in Fig. 28.

To test the accumulation of charge on the surface of the bushing, the same method was used as above, the only difference being the use of the proof plane made of lead plate, which could be easily shaped

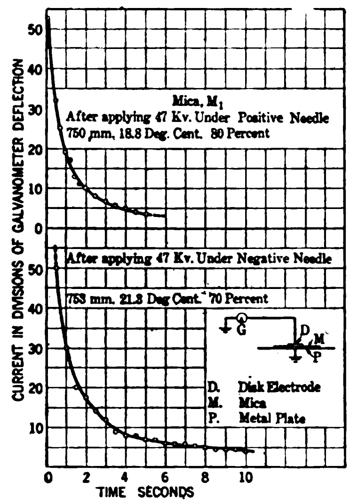

FIG. 25

so as to conform to the curved surface of the bushing. No conductor was connected to the top of the bushing, the electric field being produced by the transformer itself. The field was applied for one minute and then removed by opening the primary switch of the transformer or sometimes by opening the field switch of the alternator feeding the transformer.

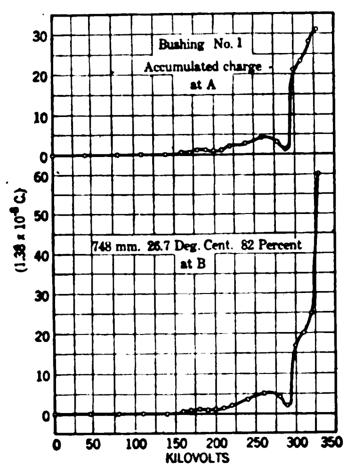

FIG. 26

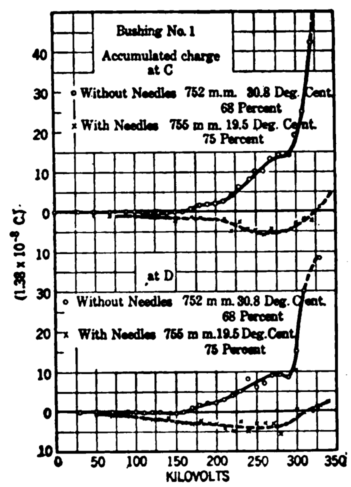

FIG. 27

The measurements of accumulated charge were made on the various parts of the surface of the bushing, the valleys as well as the ridges of the corrugation. But the typical results only are shown here in Figs. 26 and 27. In comparatively weak field, the charge accumulated was negative and it became positive as the field was increased. The appearance of a minimum value at about 290 kv. was found to be due to the starting of corona discharge from the grounded

conductors which happened to be near the bushing. On repeating the test with these conductors removed, the minimum disappeared and it was found that the surrounding conductors had a considerable effect upon the accumulation of charge, especially when the corona discharge therefrom could supply ions to the air surrounding the bushing. To ascertain this fact, we carried out another test in which eight needle points were placed symmetrically around the bushing. The relative position of each needle to the bushing was

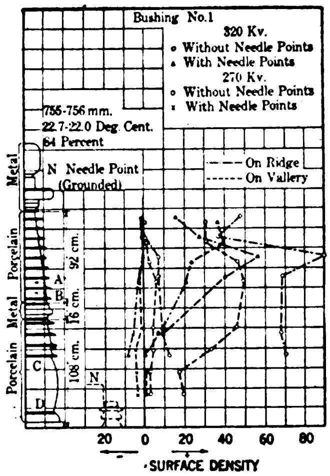

Fig. 28

as shown in Fig. 28, and they were all perfectly grounded. Then it was found that the accumulation of negative charge was increased and consequently the accumulation of positive charge was thereby suppressed to some extent, as shown in Fig. 27 and 28. In Fig. 27, the dotted curves were obtained from the measurement when the needle points were placed around the bushing. In Fig. 28, the abscissa represents the average surface density, and the ordinate the spot of observation. Each mark is connected by a broken or chain line to distinguish one series of the results from another. We can notice the remarkable effect of the needle points especially on the lower part of the bushing.

Our test was further extented to the porcelain bushings made by A. E. G. in Germany and the suspension insulators made of porcelain and boloporcelain, and it was observed that they behaved likewise in electric field of high intensity.

Another remarkable result was that relating to the effect of surface condition on the flash-over voltage. The A. E. G. bushing shown in Fig. 29, has a flash-over voltage of 161 kv. in normal conditions and the arc-over is preceded by the creeping spark on the lower part of the bushing, that is, *C* in Fig. 29. When, however, the lower part of the surface *C* was covered with a very thin film of paraffin wax as shown by hatching in the diagram, the flash-over voltage was raised up to 176 kv., that is, nearly 10 per cent higher, and the initial creeping spark disappeared except for the uniform glow over the lowermost part of the surface. This flash-over value is about the same as that of the post insulator which is exactly of the same form as the bushing.

When the same part of the surface was oiled (ordinary transformer oil), the flash-over voltage was raised up to 165 kv., and the initial surface creepage was also suppressed, but in this case, the continued exposure to a voltage near flash-over value caused the reappearance of the creeping spark.

3. Accumulation of Charge on Insulated Conductors in Electric Field of High Intensity

When the author was carrying out some high-voltage experiment using a static oscillograph, he found erratic shift of the zero point of the oscillograph. After painstaking investigation, it was found that this phenomenon was due to the accumulation of charge on the condensers which were used as multiplier of the instrument, all being connected in series so that each coating of intermediate condensers was insulated from the ground as well as high-voltage source. An idea, then, readily occurred to test the accumulation of charge on the cap and pin of the suspension insulators when they are used for suspendering high-voltage conductors and connected in series as is usually the case. If a considerable quantity of charge be accumulated on the caps and pins of the insulators, the electric stress distribution along the string of the insulators will be obviously much more favorable for flash-over than that determined theoretically from the

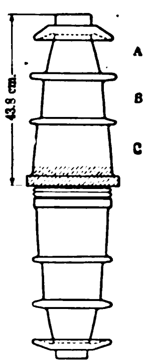

Fig. 29

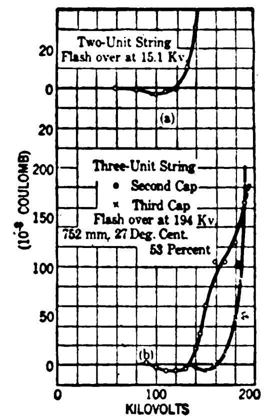

Fig. 30

charging current, *i. e.*, the capacitance between the cap and pin of each unit and the capacitances to earth and the conductor or leakage capacitances.

Of course, it is hardly possible to measure the potential or charge in working condition, and therefore the accumulated charge was measured by a ballistic galvanometer immediately after removing the alternating e. m. f. which had been applied upon the insulator string for 30 seconds. The alternating high voltage was always controlled on the primary of the testing transformer.

The results thus obtained are not very consistent with each other, but it is certain that the quantity of the charges accumulated on the caps and pins of the insulators is not so small that the potential due to these charges only is negligible as compared with the potential distribution due to the applied alternating e. m. f.

The results are shown in Fig. 30, in which the abscissa is the applied e. m. f., and the ordinate the accumulated charge.

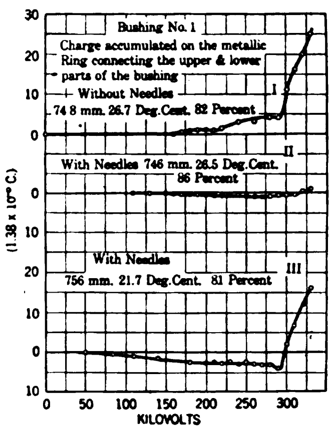

Fig. 31

The potential of the caps of the insulators due to the measured charge can be calculated if the capacitance of each unit be known. According to our measurement, the average capacitance of each unit tested was about 0.006 $\mu.\mu$.f. (0.006×10^{-12} farad).

Assuming the capacitance of each insulator to be the same and leakage capacitances negligible, the following results were obtained for the case in Fig. 30 b, after 190 kv. was applied on the string consisting of three units.

The potential of the second cap = 27,000 volts.
The potential of the third cap = 27,000 volts.

The pin-type insulator consisting of more than two shells may be considered electrically as the condensers in series, the cement layers being the coatings of the condensers. Hence, on placing the insulator in intense field, the charge will be accumulated in each cement layer. This fact was also experimentally verified just before the author's departure from Japan.

It is a well-known fact that one who touches the condenser-type bushing after it has been used is liable to get a heavy shock, if he is not cautious enough to ground the conducting layers before he touches.

Now it is very important to know why the charge is accumulated on insulated conductors when placed in intense field. At first the author had considered that the charge might be accumulated by unidirectional corona discharge from insulated conductors, and carried out some experiments to verify it. But it was not successful, and he found that there must be also another cause. Later on, the author found the accumulation of free charge on dielectric in alternating field, and now has a view that the charge on the insulated conductor is in some cases mainly that which has drifted from the dielectrics in contact with the former.

As stated in preceding paragraphs, the accumulation of charge on dielectrics depends largely upon the corona discharge at some place in the electric field and also the accumulation of charge on insulated conductors depends upon the same factor. The latter fact may be to some extent illustrated by the curves in Fig. 31, which is the result of test on the metallic ring connecting the upper and lower parts of the bushing shown in Fig. 28. The curve I corresponds to the case where the curves in Fig. 26 were obtained, and II and III to the case where needle points were placed around the bushing in two different atmospheric conditions specified on the same sheet. As may be readily seen, there is a characteristic similarity between the curves in Fig. 31 and the curves in Fig. 26 and 27.

The decay curve in this case is shown in Fig. 32, which is very interesting. The ordinates of this curve represent the ballistic throws on connecting the ring to the galvanometer, the other terminal of which was grounded. The ring was grounded for five seconds through the galvanometer and then insulated for 25 seconds. The second reading of ballistic throw was then taken, and the same cycle of process was repeated. The abscissa represents the time elapsed from the instant at which the first reading had been taken to the time of observation. Though the character of this curve resembles the ordinary dielectric absorption curve, it differs from the latter in one respect that the ratio of charge at subsequent discharge to that at the preceding discharge is far greater than in

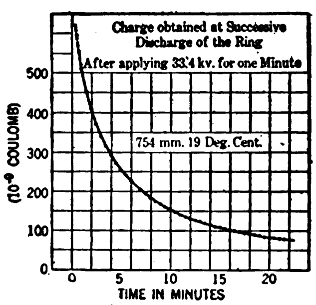

Fig. 32

the latter case. From this point the conclusion is drawn that the charge is mainly that drifted from the porcelain parts of the bushing.

Anyhow, the phenomenon is of technical importance as well as theoretical interest and is worthy of further investigation.

4. Theory of Creeping Discharge Along the Surface of Dielectrics

(a) When the electric field is of high intensity, its distribution is very different, in some cases, from that

when the intensity is low, that is, from that theoretically determined by electrostatics. Because, in intense field, there would be free charge on dielectrics as well as insulated conductors and also the space charge in air—ions—which are constantly in motion, and all these would disturb the original distribution of the field. For example, the vertical component of electric intensity may appear at a point on the surface of dielectrics where only tangential component has initially existed, or the tangential component may appear at a point where there has been the vertical component only.

From the experimental results and the discussion in the preceding paragraphs, it is conceivable that the free charge is caused to accumulate on the surface of dielectric where the vertical component of electric intensity is high. And the appearance of free charge may result in the increase of vertical component in most cases, though it does not always.

Thus, in most cases, the local concentration of dielectric flux will grow up more and more as the intensity increases, and the conditions will become worse progressively. Of course, sometimes, the appearance of tangential component may facilitate the surface creeping discharge.

(b) Owing to the accumulation of free charge and the local concentration of dielectric flux, the ionization of the air film just outside the dielectrics would be very copious, and in such conditions, the conductivity of the air film would be very high. Hence the discharge would finally take place through this layer of air. An evidence of copious ionization near the surface is the fact that there appears glow on the surface just before the occurrence of flash-over when the voltage is gradually raised; this phenomenon being familiar to persons with high-voltage experience.

(c) Owing to the presence of free charge, *i. e.* ions in the surface layer of a dielectric, the conductivity of the dielectric will increase to a value far greater than when uncharged, because it was observed that the similar change took place in resistivity in photoelectric effect on solid insulators.

(d) The surface of dielectrics, though initially absolutely clean and free from moisture, will collect fine dust and perhaps water particles also, when placed in intense field. Very probably the dust or water particles are carrying charge and tend to accumulate on the surface of the dielectric where also exists free charge. The process would be very similar to that of electric precipitation. At all events the result would be the considerable reduction of surface resistivity of the dielectric and together with the above cause, (c), facilitate the surface creeping. The evidence is the fact that after being subjected to high voltage which is just under flash-over value, the surface of the dielectric is very often found to be covered with very fine dust which adheres to the former so firmly that it can be cleaned with great difficulty. The phenomena, I suppose, are familiar with the testers of high-voltage insulators.

3. Goldmann and Kalandyk, *Ann. d. Phys.* 36 p. 589. 1911. It is noteworthy that Goldmann and Kalandyk found the paraffin wax to have the least photoelectric property out of the materials they tested, while the present research reveals that paraffin wax has the least tendency of accumulating free charge on its surface.

5. Important Factors in the Design of High-Voltage Insulation

(a) It would be liable to be misleading to design the high-voltage insulation from the consideration of classical electrostatics only or criticize the insulation already completed from the same standpoint. Because the distribution of electric field, when it is intense enough to produce corona discharge at some spots, would be far from that determined theoretically by ordinary electrostatics, since there would be free charge on the dielectrics as well as on insulated conductors and also space charge in air—ions.

(b) A little consideration on the free charge on dielectrics as well as on insulator conductors and space charge in air will lead to the conclusion that the design of high-voltage insulation should be properly modified according to whether it is to be used in alternating or unidirectional field, and if alternating, whether the frequency is high or low.

(c) Considering that the free charge on dielectrics and insulated conductors depends to a great extent on the ionization of air, it is of extreme importance to determine the best form of dielectrics and conductors, and the best choice of materials with thorough knowledge of the distribution and motion of ions in air so that air may be used as insulation with maximum efficiency.

(*d*) The accumulation of free charge on the dielectrics as well as insulated conductors depends to a great extent on the motion of ions in air. And, therefore, it is very desirable to design the insulation so that the normal component of the electric intensity on the surface of the dielectric is made as small as possible because, the accumulation of charge seems to be very copious where the normal component is high.

It is the present practise in high-voltage insulation to design the shape of the dielectric so as to make its surface conform to the direction of electric field. But such an idea comes from the consideration that if the surface is not tangential to the field, there would be possibility of producing a local concentration of dielectric flux, and not from that above stated. The result is, however, the reduction of the accumulation of free charge, and an efficient insulation was obtained. This fact is most remarkably illustrated by Fig. 27 of Gilchrest's paper (A. I. E. E. p. 584, 1918.)

(e) In some cases, it would be a wise procedure for high-voltage insulation to modify the migration of the ions by special means, such as, air blast, magnetic fields.

The experimental research on this special line is very limited. The author made a few rough tests on the influence of air blast upon the sparking voltage, but owing to the lack of powerful air compressor, the results were not noticeable.

(f) As the last discussion, a few words will be given about the efficacy of corrugations on the surface of the dielectric in the high-voltage insulation. It is a well-known fact that the flash-over voltage can be raised to a certain extent by giving corrugation to the surface of the dielectric especially when the initial sparking takes place along the surface, and also that the improper design of corrugation is not only of no use in raising the flash-over voltage but sometimes results in reduction of flash-over value. The idea prevailing among designers of high-voltage insulation is that the corrugation, rainsheds, or skirts are efficient because the leakage distance (creepage distance) is thereby lengthened and they keep certain parts of the surface dry in stormy weather. Another function is, the author thinks also to modify the moving paths of the ions, and to prevent them from drawing near to the uninjured surface of dielectric or rushing into the other part of air which is playing the most important role in sustaining the electric stress. The most important one of its functions would, howver, be to insert at a certain part of the creepage path an intact zone, that is a zone in which there is no normal component of electric intensity, and therefore, there is least possibility of accumulation of charge. The air just outside such a zone would have a strength against electric stress out of proportion to that of the air film at the other part of the dielectric. So the creeping discharge will be checked here and in consequence the flashover voltage would become somewhat higher. The evidence is the author's observation that the accumulation of fine dust on the surface in intense field is almost imperceptible on the zone, where the field is nearly tangential to the surface, when testing the porcelain bushing shown in Fig. 29.

Though now we have not experimental results enough to support the above statement, it is clear that the thoughtful design of the corrugation is of vital importance in high-voltage insulation, and improper design will not only be ineffective but detrimental for the purpose. It is obvious that the most important factors in the design are the curvature, the thickness, and spacing between the successive ridges.

ACKNOWLEDGEMENT

I have much pleasure, in conclusion, in expressing my best thanks to Prof. H. Nagaoka, Prof. H. Ho and Prof. T. Kujirai of the Tokyo Imperial University for their constant and kindly interest throughout the course of the present research, and also to Prof. Harris J. Ryan of Leland Stanford Junior University for his kindness in carrying out the radio-frequency experiment with me and his valuable criticism and careful revision during the preparation of the paper.

The present research was made in connection with the Physicochemical Research Institute of Japan and the funds for it was supplied by the Institute.

ENGINEERING SERVICE FOR BUSINESS

The head of the Bureau of Chemistry recently obtained authority from the Secretary of Agriculture to organize an Engineering Service for Business under his direction.

The following is quoted from the official statement given out by Dr. Carl L. Alsberg, Head of the Bureau of Chemistry:

The new office is engineering in its powers and personnel. Its function is a business service. It will act as the go-between from science to industry. A force of trained engineers will take up each fresh project as fast as it has passed the experimental stage in the Government laboratories, and attempt to develop its commercial possibilities. It offers, free, a service similar to that which a mining engineer performs for an investor who engages him to report on a gold mine. It will furnish reports covering everything from the source and availability of the raw material supply, to plans on the nature of the machinery needed, size of the plant, capacity of plant, cost of production and market demand for the finished material. In looking over the prospect for getting a leather substitute from a waste material, for instance, the manufacturer need not rely on his own estimates or upon the records of what the process has done on a laboratory scale. He can get reliable quantity production figures from the Office of Development Work, providing only that the process of discovery originated in the Bureau of Chemistry.

The office is a long step toward business efficiency. It talks the language of the investor, it knows his problems, and its officers are well in the forefront of modern industrial development. On the other hand it helps the Government chemist himself by popularizing his process—a thing he is often unable to do for himself. Trained and specialized in the details of his profession he is often unprepared to launch his discoveries on the sea of business. This the new office will do for him through the agency of a force especially prepared to do that very thing.* * * * For the present the work will be confined to discoveries made in the Bureau of Chemistry.

The new office is to be under the direction of David J. Price who has done a great deal of research work, notably in reducing dust explosions. The National Service Department of Engineering Council is in close touch with the work of this Bureau and is prepared to assist engineers who want special problems taken before the new Bureau.

Studies in Lightning Protection on 4000-Volt Circuits—II.

BY D. W. ROPER

Commonwealth Edison Co., Chicago.

The paper continues the investigations described by the author in another paper on the same subject presented before the Institute in June, 1916 which had for its primary object the reconciliation of the differences between laboratory experiments and experience in service.

In the paper an endeavor is made to list the several factors which affect lightning arrester performance and to describe the methods of eliminating these several variables so as to permit the presentation of curves which show the relative merits of the arresters under investigation. The elimination of the several variable factors was accomplished by placing the arresters under practically identical conditions so that no type was at any material advantage or disadvantage on account of the preponderance of the factors which would affect its performance. This was found to be possible for all of the factors except the one relating to density of the arresters, that is, the number per square mile, so that the final curves show the performance of the several types of arresters as affected by their density. These results show that four of the types of arresters are practically identical in their protective value and about 60 per cent as efficient as a fifth type, while the results for the sixth type, being limited to a much smaller number of arresters, and a shorter period of time, do not appear to be conclusive.

1. INTRODUCTION

THE investigations forming the basis of this paper as well as the previous paper[1] on the same subject had as their primary object the determination of the relative merits of the several types of lightning arresters which were installed on the 60-cycle distribution system of the Commonwealth Edison Company in Chicago. The previous investigations had indicated in a general way the several factors which affected lightning arrester performance and also the extreme variability of the distribution and intensity of the lightning storms, from which it appeared that in order to get reasonably accurate results, it would be necessary to accumulate the experience with a large number of arresters over a period of several years. The keeping of systematic records of lightning arrester performance as outlined in the previous paper was, therefore, continued and the manufacturers of the arresters were advised from time to time of the results. These data showed some slight variations from year to year, but the order of merit of the lightning arresters as shown by the figures given in the previous paper was not altered. In the meantime the manufacturers of the arresters had on their part been making investigations and experiments for the purpose of improving their designs, and one of them, as a result of such laboratory experiments, presented a table of figures which he stated represented the relative merit of the various types of arresters. The experience obtained in Chicago, however, did not substantiate the results of the laboratory experiments and placed the arresters in quite a different order. In the hope of reconciling these differences and reaching conclusions, acceptable to all interested parties, regarding the relative merits of the several types of arresters, an investigation was started about a year ago in which the manufacturers cooperated. In the following, the methods used in this investigation and the final results secured are set forth.

To be presented at the Chicago Meeting of the A. I. E. E., November 12, 1920.

1. TRANS. A. I. E. E., 1916, Vol. XXXV, p. 655.

2. DESCRIPTION OF THE SYSTEM

The system of distribution on which these investigations were made is a four-wire three-phase system, with the neutral grounded only at the substations. The normal potential on the distributing mains is 2080 volts between phase and neutral wires. The distribution pole lines are in the alleys, or along the rear lot lines in the center of the block where alleys are missing. Single-phase transformers are used exclusively and are connected between the phase and neutral wires except in the case of three-transformer three-phase installations in which case the common point of

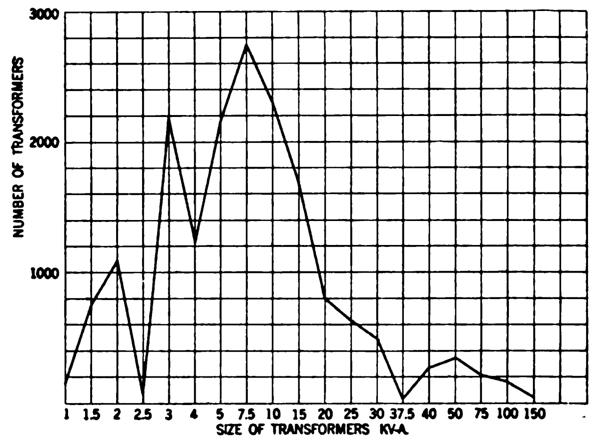

FIG. 1—DIAGRAM SHOWING THE NUMBER OF EACH SIZE OF TRANSFORMER IN SERVICE ON AUGUST 1ST, 1918

the transformer primaries is not connected to the neutral wire. Secondaries of power transformers are connected in delta. Power and lighting customers are supplied from the same primary mains, but the very large customers are connected to a 12,000-volt system. The feeders are all No. 0 wire and the mains No. 6 A. W. G. About 85 per cent of the feeders and 15 per cent of the mains are underground. About 99 per cent of the transformers are on poles and the rest in manholes or in vaults on customers' premises. At single-transformer installations a 2400-volt arrester is connected to the same phase wire as the transformer

and a 300-volt arrester to the neutral wire. Where three transformers are installed for a power service there are three 2400-volt arresters, one connected to each of the phase wires; and one 300-volt arrester is connected to the neutral wire. Arresters are installed in this manner on the same pole with all transformers. The lightning arrester ground consists of one-half inch galvanized iron pipe ten feet long, driven into

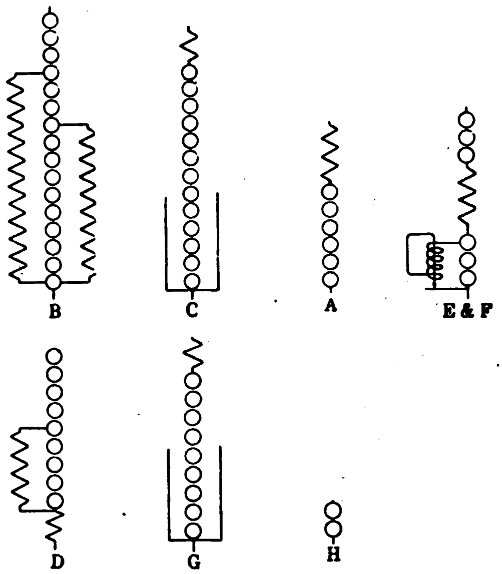

Fig. 2—Electrical Diagrams of the Lihgtning Arresters Used in These Investigations

The gaps are conventional and do not show the actual shape of the gaps on all of the arresters.

Arresters *E* and *A* have identical diagrams and differ principally in mechanical details, the amount of resistance and the length of the resistance rod.

Diagram *G* shows a type which was installed in 1920.

Diagram *H* represents the netural 300-volt arrester installed on the neutral.

the ground at the base of the transformer pole. Secondary circuits are usually less than one block long and the secondary ground is similar to the lightning arrester ground, but is installed on the next pole. On long secondaries there are at least two such ground connections and in addition the neutral wire on the customer's premises in many recent installations is grounded to the water pipes inside of the building. Where there are four primary wires in an alley they are installed on the top arm and the secondaries on the second arm. Where there are only two primary wires the lighting secondaries may be installed on the same arm. More than 80 per cent of our poles are owned jointly with the Telephone Company, and there is a minimum clearance of four feet between the wires of the two companies. In order to regulate the voltage properly, the area supplied by each feeder is divided into three portions corresponding to the three phases, and the single-phase lighting load in each portion is all connected to one phase. Arresters similar to those installed for the protection of transformers are installed on the cable poles where the underground feeders or mains connect with the overhead wires. The distribution system at this time includes about 100,000 poles, 20,000 transformers with a total capacity of about 270,000 kv-a., 6500 conductor miles of overhead primary line wire, 2200 conductor miles of underground cable and 2500 cable poles. The system serves about 400,000 customers.

In Fig. 1 is shown the number of each size of transformers on the line as of August 1st, 1918. This date was selected for the purpose of the calculations, as the number of transformers in service on that date was about the average of the number in the five-year period under investigation. Fig. 2 shows electrical diagrams of all of the lightning arresters used in the investigations. The letters shown on this diagram are consistently used throughout the several tables, diagrams and curves. Fig. 3 shows graphically the number of transformers on the distribution system over a period of years, as well as the percentage of transformer primary fuses blown and transformers burned out by lightning each year. The increase in the percentage of fuses blown during the years 1918 and 1919 was due to causes definitely known to be entirely distinct from lightning, but as some of these fuses were blown during the same day as lightning storms, they were included with fuses blown by lightning because of the impossibility of accurately determining just which fuses were blown by lightning and which by other causes.

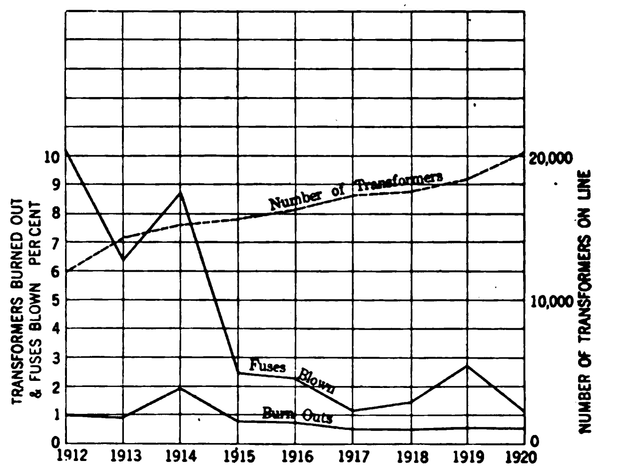

Fig. 3—Graphical Record Showing the Number of Transformers in the Distribution System and the Per Cent of Transformer Troubles Each Year Over a Period of Years

In Fig. 4 is shown the percentage of burn-outs of transformers for each storm during the five-year period and also for the year 1920, the percentages being plotted cumulatively. From these records it will be noted that it is not unusual to have over one-third of the total trouble in any one year due to lightning occur in one or two days. A composite of these curves for the five-year period is shown in Fig. 5, from which it will be noted that on the average, the

lightning is quite uniformly distributed throughout the 4½ months from May 1st to September 15th, and that there is comparatively little trouble outside of this period.

Fig. 6 is an outline map of the portion of the city covered by the distribution system on August 1st, 1918, showing the section lines and the lightning arrester area numbers. These areas will be found to differ from those shown in the previous paper as some changes were made in 1917 for the purpose of trying another type of arrester, a new scheme of protection and incidentally securing a little better distribution of the various types of arresters over the different portions of the city. The shaded areas on this diagram will be referred to later in the paper.

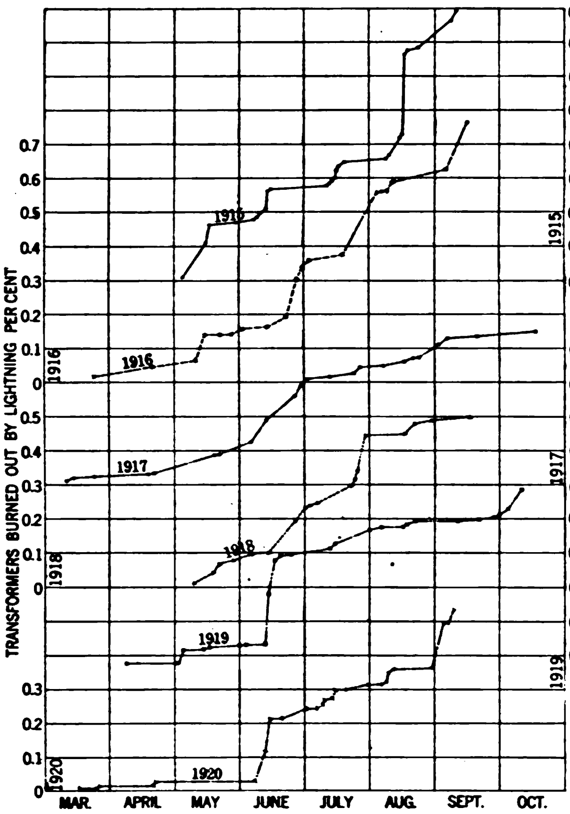

Fig. 4—Diagram Showing the Percentage of Transformers Burned out in Each Storm for the Years 1915-1919 Inclusive

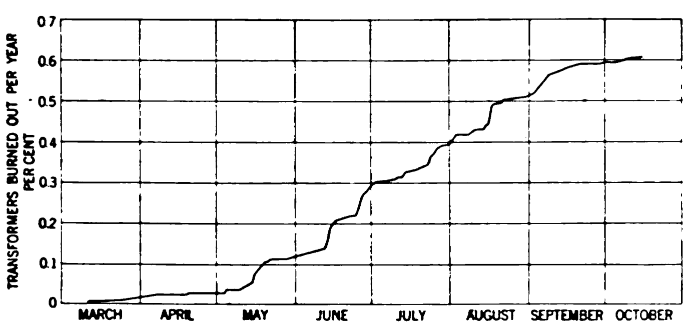

Fig. 5—A Composite Diagram of the Transformer Burn-Outs for Years 1915-1919 Inclusive

3. Preliminary Investigations

From the previous paper and subsequent studies it appears that the factors which might affect lightning arrester performance are as follows:

1. The system of distribution and the grounding of the neutral.
2. Primary terminal boards.
3. The shielding effect of trees, buildings or wires of other companies.
4. The resistance of the lightning arrester ground connection.
5. The maker of the transformer.
6. The size of the transformer.

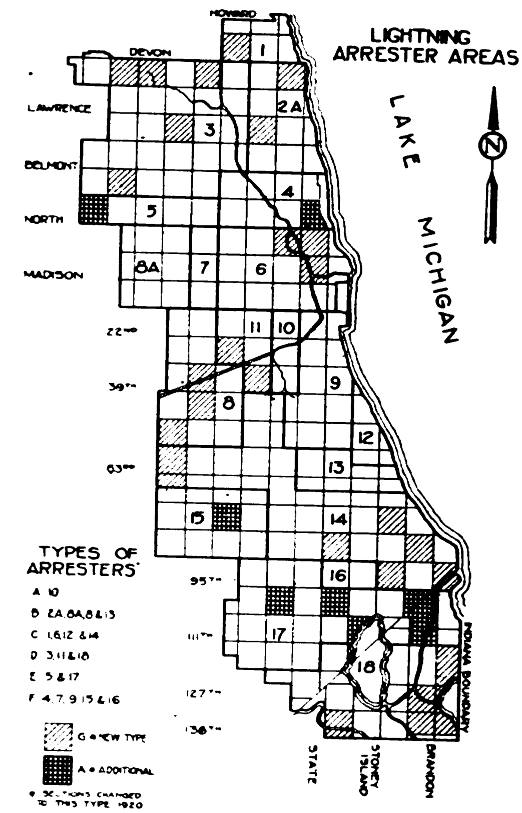

Fig. 6—Outline Map of the City, Showing Section Lines and Lightning Arrester Area Numbers

The lightly shaded areas show the sections in which arrester *G* shown in Fig. 2 was installed in 1920. The heavily shaded portions show the sections in which additional arresters of type *A* were installed in 1920 for the purpose of getting more conclusive information regarding this type.

7. The age and previous service record of the transformer.
8. Variation in the distribution and intensity of the lightning.
9. The density of lightning arresters, that is, the number per square mile.
10. The design of the arrester.

Records were available for the five-year period 1915 to 1919 inclusive and these records were carefully compiled in great detail and arranged systematically so as to set forth all facts which might influence the results. The history of each burnt-out transformer from the date of its purchase to the time of its burn-

out was also assembled and tabulated. In Chicago the same system of distribution is used throughout the entire city and the neutral is grounded at each of the substations from which the circuits emanate, so that all types of arresters, as far as this point is concerned, are installed under identical conditions.

The previous paper describes the earlier experiments which prove the disadvantage of primary terminal boards within the transformer case. As a result of these investigations the practise was established of removing the terminal boards from all transformers which were returned from the lines to the storeroom for any purpose such as changes on account of increased load or discontinuance of service. The number of transformers which returned to the storeroom in this manner during a year was on the average about equal to the number of new transformers added to the system so that the percentage of transformers in service with primary terminal boards was rapidly reduced. It appeared from this investigation that the percentage of transformers with primary terminal boards was so low and the transformers so well distributed over the system that they had no appreciable effect on the relative performance of the lightning arresters.

In laying out the lightning arrester areas which were given in the previous paper, and which are also shown in Fig. 6 in this paper, it was the intention to arrange the boundaries of the areas and to distribute the several types of lightning arresters over the city so as to eliminate variables 3 to 8 inclusive as given in the above list. In order to determine whether this result had actually been secured, the records of the transformer burn-outs due to lightning were carefully investigated in cooperation with the manufacturers of the arresters. The previous paper had indicated the difference in the results as effected by the maker and the size of the transformer. In investigating these points we assumed that if the percentage of burn-outs of any one maker or any size of transformer which had been protected by any type of arrester were not seriously different from the percentage of such transformers protected by that type of arrester to the total on the system, that no type of arrester was at any disadvantage due to unequal distribution of such transformers on the system.

An investigation of the records demonstrated beyond question that the shielding effect of trees or buildings immediately adjacent to the lines considerably reduced the amount of damage on our lines from lightning. This was shown by the following facts:

(a) The percentage of poles in the distribution system shattered by direct strokes is extremely small, being of the order of 1/400 of 1 per cent. This is very much smaller than the corresponding percentage for transmission line poles belonging to the same company in the flat open country in the southeastern portion of the city and is also smaller than experienced in general by companies having transmission lines crossing open country. That there are many direct strokes in every severe lightning storm is shown by the newspaper reports on the day following lightning storms, which record the most severe or unusual cases of damage to trees, church steeples, chimneys, or other portions of buildings and structures.

(b) An investigation of the conditions surrounding the installation of 97 out of 529 cases covered by these investigations where transformers were burned out by lightning failed to reveal a single case in which the primary wires adjacent to the transformer were overshadowed by high trees or buildings immediately adjacent.

By "spot checking" selected portions of each of the lightning arrester areas in cooperation with the representatives of the manufacturers, it appeared, although the shielding effect of trees and buildings was considerable, that as far as could be determined without making a detailed survey and record of the conditions in each block throughout the city, no type of arrester was at any serious advantage or disadvantage on this account.

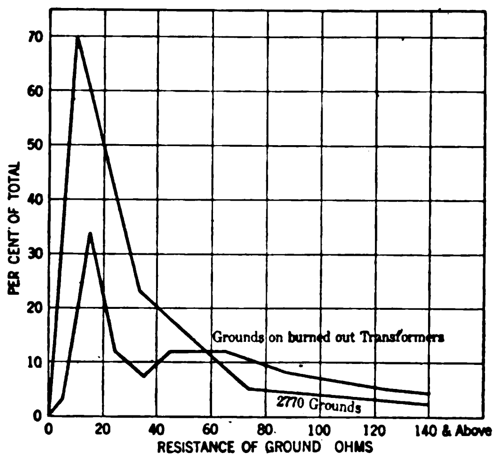

Fig. 7—Results of Tests of Resistance of Grounds

The line showing grounds on burned out transformers was made up from tests on arrester grounds at locations where 97 transformers burned out in 1919. The curve marked 2770 grounds shows the results of tests made in 1917 in cooperation with representatives of the Bureau of Standards.

With the idea that some of the transformer burnouts might have been due to ground connections having a resistance so high as to render the arrester ineffective, the resistance was measured at 97 locations where the surrounding conditions were also noted in detail, and the results are shown in Fig. 7. On the same figure is shown, in a similar way, the resistance of 2770 grounds, both lightning arrester and secondary grounds, which were tested in 1916. It will be noted from this figure that the resistance of the lightning arrester grounds at the points where the 97 transformers were burned out by lightning averaged slightly above the resistance of the much larger number tested three years earlier. It therefore, appears that the burn-outs were not due to particularly bad ground connections

for the lightning arresters at the locations where the transformers burned out.

In the same manner the records and the conditions surrounding the transformer installations were carefully and thoroughly examined to determine the effect of the other points 5, 6 and 7. These investigations included the assembling of the complete history of each transformer that had burned out during the five-year period and the compiling and assembling of all data which might serve to add to the information on the several points. On the completion of the investigation, the representatives of the manufacturers concurred in the decision that none of the arresters appeared to be at any material advantage or disadvantage on account of the first seven variable factors in the above list, and these factors were, therefore, ignored in the further investigation.

There still remains two variables, namely the variability of the lightning, and the density of lightning arresters. In determining the relation between the density of lightning arresters and their performance, a method was discovered of eliminating the effect of the lightning as a variable as described at some length later in the paper.

4. The Effect of Density of Lightning Arresters on Their Performance

A preliminary investigation of the effect of density was made by plotting the density of arresters in each original lightning arrester area against the percentage of burn-outs in that area. The points plotted in this manner were so irregular that they did not permit the drawing of any curve which might be considered as representing the results, but the method appeared to indicate that there was a very marked decrease in the percentage of burn-outs with increase in density which would warrant further investigation along this line. The results also indicated that some further subdivisions of the original lightning arrester areas would be necessary in order to eliminate the lightning as a variable. The manner in which the records were kept enabled this change to be made very readily by using the section (that is, the square mile) as the unit, resulting in an increase in the number of areas from 19 to 192. For each one of these sections there was determined from the records the number of transformers in the section as of August 1st, 1918. As there is an arrester on the same pole with each transformer, and comparatively few cases where there were two transformers connected to the same phase wire on the same pole, the number of transformers in each section was taken as the number of arresters. There was also determined for each section the number of transformer burn-outs and primary fuses blown by lightning during the five-year period and the actual area covered by the line. This latter quantity was determined by going over the large scale maps of the distribution system and assuming that a line through the center of the block covered the width

TABLE I

DATA FOR DETERMINING THE EFFECT OF DENSITY OF ARRESTERS ON THEIR PERFORMANCE

The types of arresters are indicated in Fig. 2, the area numbers are shown in Fig. 6, the section numbers in Fig. 11. The stars (*) indicate the sections in which the type of arrester was changed in 1917. Figures for the average curve are taken from this table but due allowance for this change was made in plotting the curves for the individual arresters.

Present type of arresters	Area number	Section number	Number of transformers in section	Number of burn-outs in section	Number of fuses blown in section	Area actually covered by lines	Density of arresters per square mile	Average per cent burn-outs per year

Density of shading indicates the density of lightning arresters.

tions arranged in the order of density of arresters are shown in Table I.

The data in this table and other data regarding the system are shown graphically in several drawings which give a better idea of the conditions than can be obtained from tables of statistics. In Fig. 8 is shown an outline map of the city on which are shaded the areas actually covered by the lines, the number of arresters per square mile being indicated by the density of the shading. The distribution system extends into 192 sections covering 163.25 square miles within the city, while the area actually covered by the lines, determined in the manner above described is 93.49 square miles. As there were 17,529 transformers on the lines on August

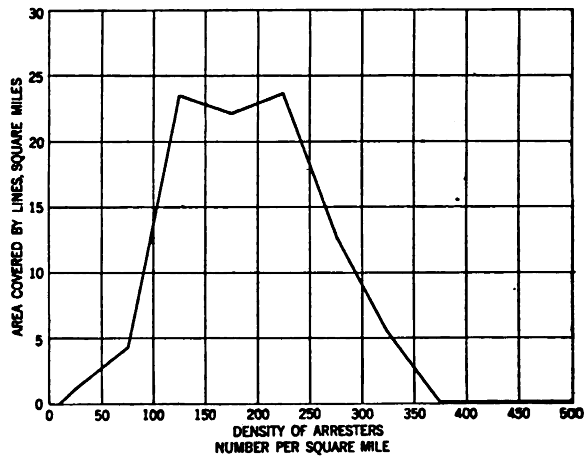

FIG. 9—DIAGRAM SHOWING THE AREA ACTUALLY COVERED BY THE DISTRIBUTION SYSTEM FOR VARIOUS DENSITIES OF ARRESTERS

1st, 1918, the average density of arresters is thus 187 per square mile.

Fig. 9 shows these data in another manner, from which figure it will be noted that in the larger portion of the area covered by the distribution system, the density of arresters ranges between 100 and 300 per

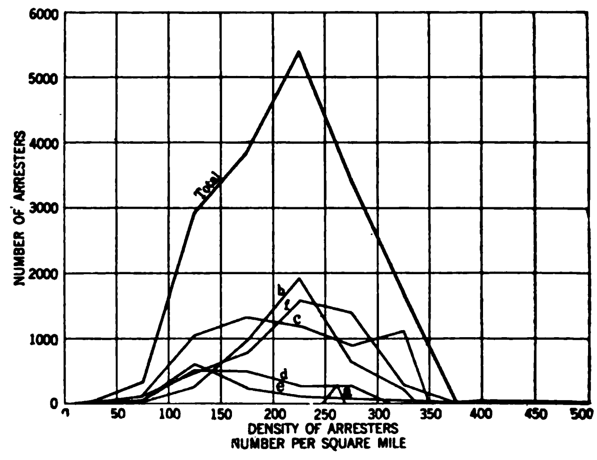

FIG. 10—DIAGRAM SHOWING FOR VARIOUS DENSITIES OF ARRESTERS THE NUMBER OF EACH TYPE OF ARRESTER AND OF ALL TYPES CONNECTED TO THE DISTRIBUTION SYSTEM

square mile. The number of arresters for various densities and for each type of arrester is shown in Fig. 10. In this drawing it will be noted that arrester *A* was installed in sections with a very narrow range in density. The section numbers given in the third column in Table I are shown in Fig. 11. The stars preceding the section numbers in Table I indicate the

sections in which a change in the type of lightning arrester was made preceding the lightning season of 1917 for the purpose of permitting the installation of an additional type of arrester and securing a better distribution of the several types of arresters in different portions of the city.

In Fig. 12 there has been plotted for each section the density of arresters as shown in the eighth column

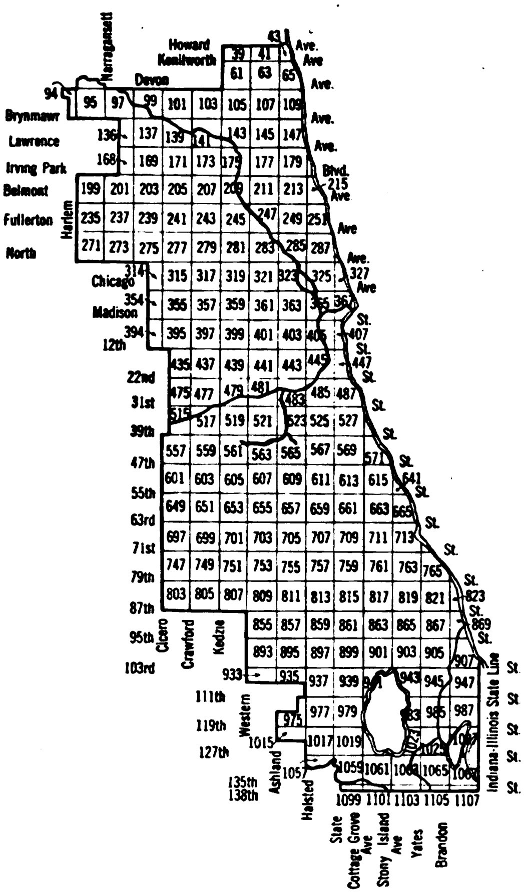

Fig. 11—Outline Map of Chicago, Giving the Numbers Assigned to Each of the Sections as Shown in the Third Column of Table I

in Table I and the average per cent of burn-outs as shown in the last column. The final curve for all arresters showing the variation in the performance of arresters with their density is also shown in the same figure, but the curve cannot be drawn directly from the points shown in this figure because these points, representing different areas and different numbers of transformers, are not of equal weight. Nothing in the tables or records shows the wide variation in the distribution and intensity of the lightning quite so well as the plotting of these points in Fig. 12. Out of the 192 sections it will be noted that in about one-sixth of them the points are on the line of zero burn-outs, showing that there were no burn-outs whatever in these sections during the five-year period.

In order to secure points of equal weight for the purpose of drawing the curve, it was decided to have each point represent the experience with the same number of transformers. At first trial it was agreed to assemble the data so as to get 18 points, each of which would therefore include the data from approximately 1000 transformers. The data for the first point were obtained by starting at the top of Table I and including enough sections to get a total of about 1000 transformers. Then the figures showing the area covered and the number of burn-outs was totaled for these sections, from which could be determined the average density of the arresters and the average per cent of burn-outs for this group of transformers. This was equivalent to taking a vertical band of Fig. 12 which would include enough points to make a total of 1000 transformers and finding one point to represent the average experience for the entire band. In the same way the other 17 points were calculated and are shown plotted to logarithmic coordinates in Fig. 13. The use of logarithmic coordinate paper was adopted for the purpose as it was found to greatly facilitate the work. There was some question as to whether the number of points selected for assembling the data in this manner had any effect on the resulting curve, but it appeared that if practically the same line were obtained by using a different number of points that there would be no serious error in the method. The same data were therefore assembled in a similar manner in 7 points, 4 points and 2 points and the results are

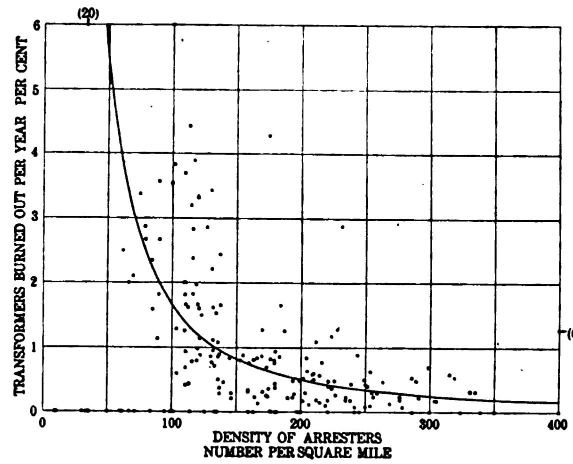

Fig. 12—Diagram Showing for Each of 192 Sections the Average Per Cent of Transformer Burn-Outs Due to Lightning for the Five-Year Period Plotted Against the Density of Arresters

The curve shows for all types of arresters the final determination of the relation between density of arresters and transformer burn-outs due to lightning. The curve cannot be plotted directly from the points shown in the figure as they are not of equal weight.

shown respectively in Figs. 14, 15 16. After a number of attempts to draw curves through these points in the several figures, it was found that a straight line would properly represent the results just as well as any curve which might be drawn; and it was, therefore, assumed that the curve when drawn on logarithmic coordinate paper was a straight line, which is equivalent to assuming that the relation between the quantities is an exponential function. In each of the four figures the

full line is determined by the points in that figure and the dashed line is the average of all of the four. It will be noted that the variation of the points through the straight line decreases as the number of points decreases, or in other words, as the number of trans-

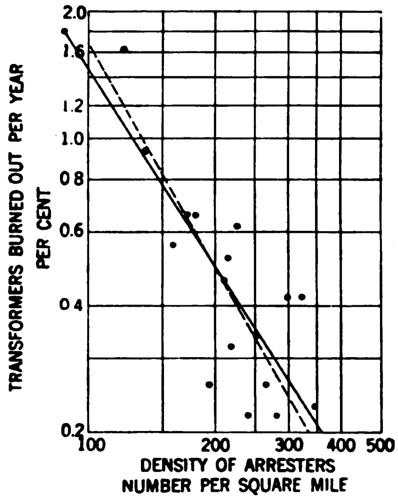

Fig. 13—Diagram to Logarithmic Scale Showing the Data in Table II and Fig. 11, Assembled into Eighteen Points Each Covering the Experience for the Five-Year Period With Approximately the Same Number of Transformers

formers represented by one point increases. The average curve represented by the dashed line in these four figures transferred to arithmetical coordinates is shown in Fig. 12.

While one engineer was engaged in the task of

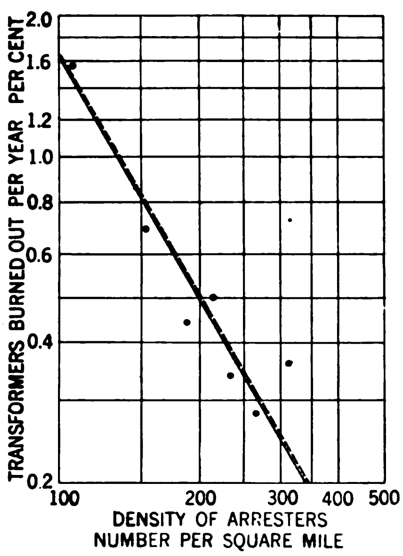

Fig. 14—Same as Fig. 12 Except That Data are Assembled Into Seven Points of Equal Weight

assembling the data and drawing the lines on logarithmic coordinate paper as above described, another engineer was given the task of assembling the data in a similar manner except that he used for each point the experience from an equal area covered by the lines as given in column seven of Table I, instead of an equal number of transformers. This was done with the idea that any serious personal errors or any error due to the assumptions made in drawing the curves or in transferring them to arithmetical coordinate paper would be indicated by differences in the final curves. After these two engineers had independently drawn final curves similar to the one shown in Fig. 12 the two curves were then transferred to the same sheet and found to be practically superposed. The equation of the curve in Fig. 12 is:

$$Y = \frac{5450}{X^{1.75}}$$

where X = the number of arresters per square mile, and
Y = The average per cent of transformers burnt out by lightning per year during the five-year period.

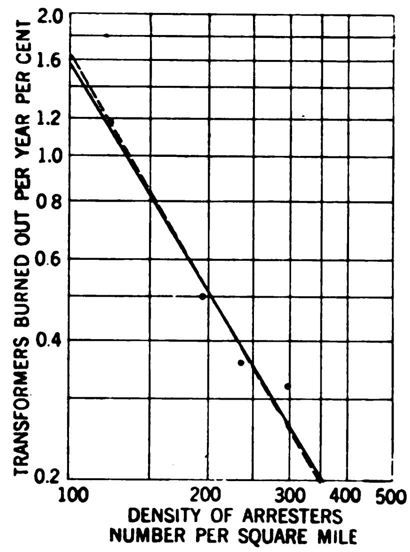

Fig. 15—Same as Fig. 13 Except That Data are Assembled Into Four Points of Equal Weight

This equation means that the density of arresters has a very important influence on the results secured by lightning arresters. If we assume for example, that there are 1000 transformers installed in an area of 10 square miles each protected by an arrester on the same pole, and that later the number of transformers in this area is doubled and at the same time uniformly distributed, the results of the change are shown in Table II. From this table it will be noted that although the number of transformers in the area has been doubled, the percentage of burn-outs has decreased from 1.67 per cent to 0.5 per cent and that the actual number of burn-outs has decreased from 17 to 10 per annum. In other words, the doubling of the number of transformers and arresters in a given area will not result in more transformers being burnt out by lightning per year as might be supposed, but will result in an actual reduction of about 40 per cent in the number of such burn-outs per year.

The data for each type of arrester were then plotted in a similar manner, a set of four curves similar to Figs. 13, 14, 15 and 16 being drawn for each type of arrester. As might be expected with a smaller number of observations, the variation of the points from a straight line when plotted on logarithmic paper and the variation of the four lines from their average was somewhat greater than in the case of the corresponding lines for all types of arresters. These straight

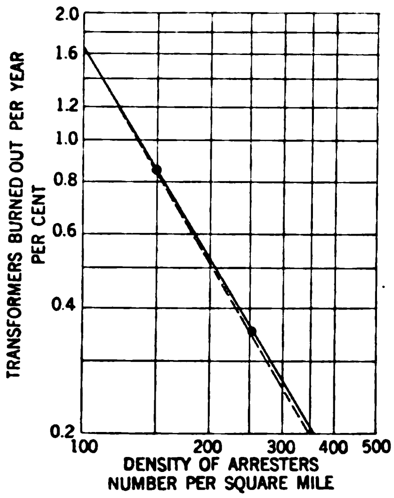

Fig. 16—Same as Fig. 14 Except That the Data are Assembled Into Two Points of Equal Weight

lines for the different types of arresters were not parallel, and when transferred to arithmetical coordinate paper as shown in Fig. 17, the curves cross each other in a confusing manner. While the curves thus drawn may be mathematically accurate, they appear to be physically impossible as there seems to be no sufficient reason why one type of arrester should be better than another at one density and poorer at another density. It seems more reasonable

TABLE II

CALCULATIONS FROM ASSUMED DATA SHOWING THE EFFECT OF DOUBLING THE DENSITY OF ARRESTERS AND TRANSFORMERS

No. of arresters and transformers	Area square miles	Density of arrester	Average annual transformer burn-outs due to lightning	
			Per cent	No.
1000	10	100	1.67	17
2000	10	200	0.5	10

to suppose that if one arrester is better than another at any particular density of arresters, it will be better throughout the entire range of densities. After giving this subject considerable study it was decided to assume that the straight line representing the experience with any type of arrester, when plotted on logarithmic coordinate paper should be parallel to the line showing the results for all types of arresters, that is, the dashed line in Fig. 13. To make this change: the midpoint of the line for each arrester was found, which is a point so located that there are an equal number of arresters represented by the line on either

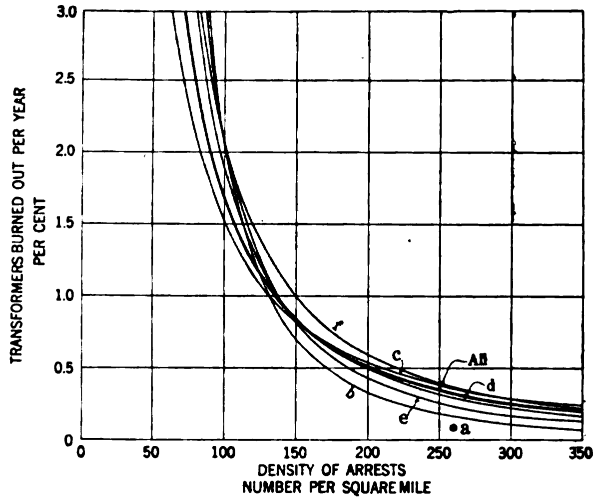

Fig. 17—Diagram Showing the First Approximation of the Relation Bweteen the Density of Arresters and the Percentage of Transformers Burned Out by Lightning for the Five-Year Period, 1915-1919 Inclusive

The curve for all arresters is plotted from the dashed line in Figs. 13 to 16 inclusive. The curves for the individual types of arresters were derived in a similar manner from logarithmic diagrams which are not reproduced.

A point instead of a line is shown for arrester *A* as the records for this type include only one transformer burn-out in the three years in which the arresters have been in service.

side of the point. The line which was finally taken as representing the experience with this type of arrester was then drawn through this midpoint and parallel

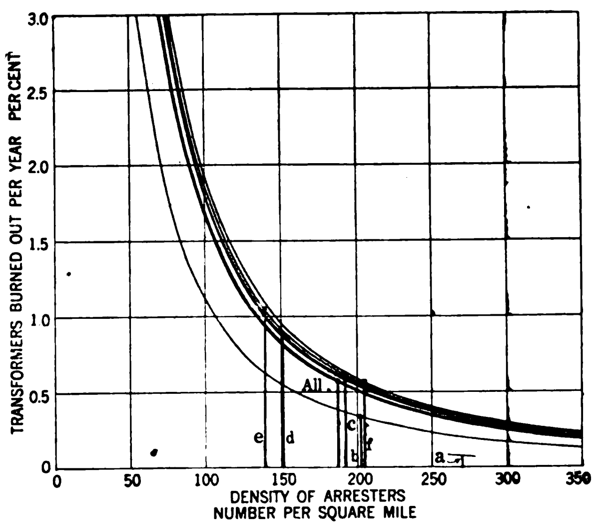

Fig. 18—Diagram Showing the Final Determination of the Relation Between the Density of Arresters and the Percentage of Transformers Burned Out by Lightning

These are the curves shown in Fig. 17 modified by the assumption that the lines representing the data on logarithmic paper should be parallel to the dashed line in Figs. 13 to 16 inclusive, showing the experience with all types of arrester.

to the dashed line in Fig. 13. The results of this assumption when transferred to arithmetical coordinate paper are shown in Fig. 18. If these several

assumptions are reasonably accurate, and they appear to do no violence to the facts, then the methods which have been used result in curves which can be taken as representing the performance of each of the arresters with varying densities, and the most troublesome variable, that is, the variation in the distribution and intensity of the lightning has been eliminated by the method of assembling the data and drawing the curves. From these curves it will be noted that four

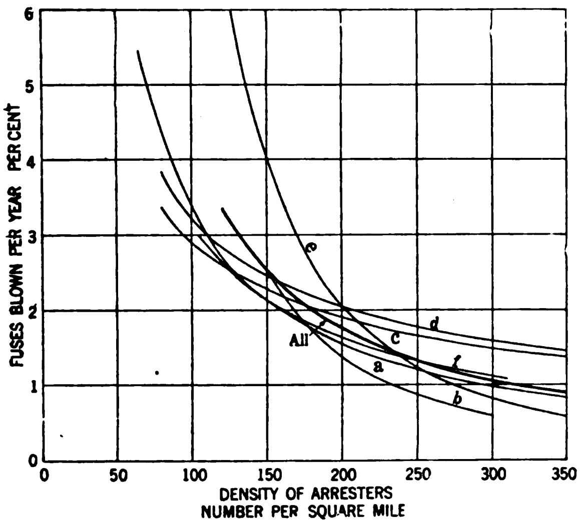

Fig. 19—Diagram Showing the First Approximation of the Relation Between the Density of Arresters and the Percentage of Transformer Primary Fuses Blown by Lightning, Plotted in the Same Manner as the Curves in Fig. 17

The curve for arrester *A* in this and the following figure was secured by using the records by quarter sections so as to secure an increased number of points.

of the arresters designated as *C*, *D*, *E* and *F* are so close together that the differences may be considered as well within the possible errors of observation.

In Fig. 18 an ordinate has been drawn to the mid-point of each of the curves as above defined or at the position corresponding to the average density for that curve, that is, for each type of arrester the number of arresters to the right of the ordinate is the same as the number to the left. These ordinates represent the same values that were given in the previous paper as showing the average experience for each type of arrester, but it is now seen that in the case of the four arresters *C*, *D*, *E* and *F*, the curves are so close together that the ordinates for these curves, instead of correctly representing the relative merits of the four arresters, are practically four different ordinates of the same curve. The four arresters are therefore of practically equal protective value.

It will be noted that the ordinates for curve *B* in Fig. 18 are about 40 per cent of the corresponding ordinates of the average of curves *C*, *D*, *E* and *F*. Arrester *B* is one of the oldest types on the lines and the arresters are fairly well distributed over a wide range of density as shown in Fig. 10. It is, therefore, considered that this difference of about 40 per cent as compared with the other four is a real difference due to the value of the arrester as a protective device and is not due to an error in the observations or calculations.

In the case of arrester *A*, Fig. 6 shows that this arrester was installed in only three contiguous sections and Fig. 10 shows that these sections had a narrow range in arrester density. In addition the arresters had been in our service for only three years and in view of all of these circumstances, it appears that the data regarding this particular type of arrester are not conclusive. For the purpose of securing more conclusive data regarding this type of arrester, additional arresters were installed early in 1920 in the areas shown by the heavy shading in Fig. 6. The light shading in the same figure shows the areas in which an additional type of arrester was installed early in 1920.

The data showing the relation between density of arresters and the per cent of primary fuses blown by lightning were treated in the same manner as the data for the transformer burn-outs, and the results are shown in Figs. 19 and 20. On account of the fuse trouble experienced in 1918 and 1919 as mentioned earlier

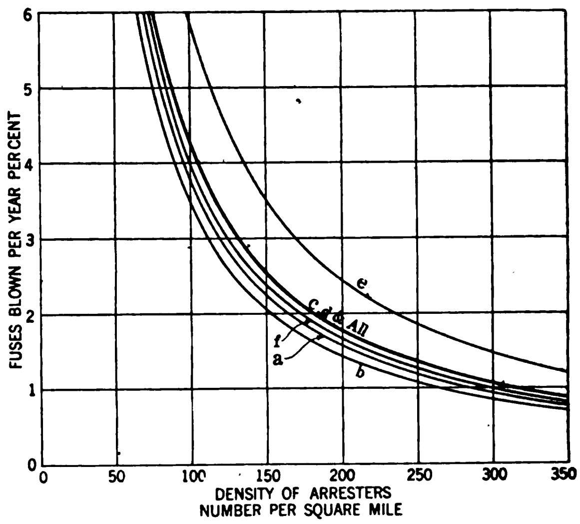

Fig. 20—Diagram Showing the Final Determination Between the Relation of the Density of Arresters and the Percentage of Transformer Primary Fuses Blown by Lightning During the Five-Year Period 1915-1919 Inclusive

Plotted in the same manner as the curves in Fig. 18.

in the paper, the percentage of fuses blown which have been ascribed to lightning in the two years is known to be higher than the actual figure. This trouble was eliminated by the change of all the fuses to a new type during the latter months of 1919 and the earlier months of 1920. The marked reduction in the percentage of fuses blown by lightning in 1920 indicates that this particular form of fuse trouble has been eliminated. The principal cause of the blowing of transformer primary fuses in lightning storms is due to the arcing

across the bushings where the primary wires enter the transformer case, and the scars from these arcs can generally be located. Some of the transformer manufacturers have increased the size of these bushings in their later designs and our records indicate a considerable reduction in the amount of trouble from this cause with the enlarged bushings.

On account of the nature of this trouble and on account of the several factors which modify the results, it is thought that the curves in Fig. 20 are less accurate than the corresponding curves for transformer burnouts as shown in Fig. 18. The curves are, however, of the same general shape and show that there is a marked decrease in the percentage of fuses blown to the increase in density. The equation of the curve for all arresters in Fig. 20 is

$$Z = \frac{1300}{X^{1.75}}$$

where X = the number of arresters per square mile

and Z = the per cent of fuses burnt out due to lightning.

The investigation discloses a remarkable decrease in the percentage of transformer troubles caused by lightning with the increase in the number of arresters per square mile. The curves show further that there is a rather high percentage of troubles for the very low densities, and in those systems where the transformers, each of which is protected by an arrester on the same pole, are located several blocks apart, it is possible that although the arresters are actually of considerable benefit, the percentage of troubles is still so high that there may be some doubt in the minds of those in charge of such systems as to the value or even the advisability of installing lightning arresters. Where such conditions exist, the installation of additional arresters would in all probability reduce the percentage of trouble caused by lightning to such an extent that their installation would be entirely warranted by a reduction in operating expenses.

5. Lightning Arresters on Cable Poles

As indicated in the description of the system, about 25 per cent of the primary feeders and mains are underground, and there are about 2500 cable poles where the underground feeders or mains are connected to the overhead wires. At all of these cable poles each of the cables is protected by an arrester installed on the cable pole in a manner similar to those installed on transformer poles. These arresters have not been included in figuring the density of arresters for the protection of transformers.

It is a matter of common knowledge in Chicago that some years ago when the number of substations supplying the system was only one-fifth of the present number and when the average distance between transformers was considerably greater than at present, that there was a large percentage of cable troubles due to lightning. This was particularly true where a short length of underground cable required for the crossing of a boulevard or a branch of the Chicago River or by other local conditions was of necessity inserted in a long stretch of overhead line. The records also show that although the load has increased more than tenfold since that time and the number of cable poles has probably increased in an even greater ratio, the annual number of burn-outs of such cables due to lightning has not increased and has probably been reduced. In 1918, for example, when the amount of damage to transformers by lightning was about the average for the five-year period as shown by Fig. 4, there were only three burn-outs of cables due to lightning, all of which occurred either at or in the vicinity of the cable poles. This number was about 1/15 of 1 per cent of the total number in service. This information, together with the curve in Fig. 18, leads to the conclusion that the arresters which have been installed on our lines for the protection of transformers must also assist in the protection of cables connected to the overhead lines. It also appears to be equally true that the arresters installed on the cable poles must assist in the protection of the neighboring transformers. These cable poles are fairly well scattered over the entire system and an examination of the maps and a count of the arresters on cable poles in a few sections indicates that the arresters on cable poles bear a fairly constant ratio to the arresters on transformer poles. If these arresters on the cable poles were included in calculating the density of arresters in Table I and in Figs. 17, 18, 19 and 20, it would probably be found that the curves in these figures would be slightly altered in their position without materially altering their form. The omission of the lightning arresters on cable poles in connection with Table I and the curves which follow does not appear to be a serious error as the exact values of the percentage of burn-outs or of fuses blown for any given density refer specifically to Chicago conditions, while the form of the curves probably represents a fundamental principle in lightning protection.

If the density of the arresters in the vicinity of a cable pole is an important feature of lightning protection for cables connected to 4000-volt lines, it should be equally important in connection with arresters for the protection of cables connected to higher voltage lines. In and near many of the larger cities it is a quite common practise to have a number of lines partly overhead and partly underground operating at voltages from about 6000 to 25,000. There is a wide difference in the practise of various companies in the protection of such cables from lightning; some companies claim that so little benefit has been received from the installation of lightning arresters on their 13,000 or 25,000-volt cable poles that they are no longer installed; other companies consider that the

probability of interruption due to lightning is so great that they do not connect overhead lines to underground cables except in substation buildings where there are also installed transformers for changing the voltage, together with the usual equipment of arresters for the protection of the transformers. The transformers installed in this manner serve to isolate the overhead line from the underground cable and thus effectively protect the cable from lightning.

In such cases where lightning arresters are installed at points where high-voltage cables are connected to overhead lines, no company installs more than a single arrester. In Chicago there are a number of such cable poles on 12,000 and on 20,000-volt cables, and the percentage of burn-outs of these cables due to lightning is of the order of 10 per cent per annum, while in the 4000-volt cables it is a small fraction of 1 per cent. In view of this experience and of the curve showing the effect of density of arresters on the efficiency of the protection of line transformers, it appears that the high percentage of burn-outs experienced with the high-voltage cables is largely due to the low density of arresters in the immediate vicinity of the cable pole, and that a very considerable reduction in the percentage of such burn-outs could be secured by the installation of additional arresters in the vicinity of the cable pole.

6. Comments on the Designs of Lightning Arresters Covered by this Investigation

The earlier types of lightning arresters were all made with the metal parts enclosed in a wooden case so that the arresters could be periodically inspected, adjusted and repaired. The arcing parts were so designed that they could be readily renewed. The practise was to make an annual inspection followed by the necessary adjustment, repairs and replacements, and this annual overhauling was a serious item of expense.

Early in the period covered by these investigations, one of the manufacturers brought out a type of arrester which was self-contained, that is, the metal and other current-carrying portions of the arrester were assembled in a porcelain casing which did not require an external wooden box for its protection. In this type of arrester the metal parts and resistance rod are assembled in a porcelain housing, the several parts being fastened together by means of a sealing compound so that it is not feasible to inspect or repair these arresters while they are in position on the poles. The gaps in this new type, instead of being between brass points or spheres, are between round parallel plates so that a number of successive heavy discharges will not seriously alter the total length of the gaps. After several years' experience with this type of arrester, the conclusion was reached that such arresters had many advantages over the wooden box type besides a considerably reduced annual maintenance charge and it appeared entirely possible to make such arresters so that they would have a protective value equal to the earlier wooden box type. On reaching this decision the manufacturers were advised that no further purchases would be made of arresters which required a wooden box for their protection. Several types of arresters have been produced by the manufacturers since that time and several modifications in the design of the arresters have been made as a result of the information from these investigations which were communicated to the manufacturers from time to time. It is possible that the experience with the several types of arresters covered by these investigations, as well as the earlier types which they replaced, may be best summarized in the form of a tentative specification for lightning arresters, which would state some of the important points to be included and to be avoided in such design. Such a specification would read about as follows:

1. The arrester must consist of a number of gaps in series with a resistance, with the number of gaps and the amount of resistance properly adjusted to the line voltage so that the dynamic arc following a lightning discharge will be quickly broken without damage to the arrester.

2. The resistance rod must have the resistance uniformly distributed throughout its length, so as to prevent the progressive short-circuiting of the rod with heavy lightning discharges and the destruction of the arrester which will follow.

3. The amount of resistance in the resistance rod should not be seriously affected by repeated heavy discharges.

4. The leads for connecting the arrester to the line should leave the arrester so that they will form drip loops, and the leads should be so arranged that the arrester can be connected to a line wire on either side of the arrester.

For low maintenance cost the following features are desirable:

5. The enclosing case should be of fireproof insulating material that is not affected by the weather; and it should be constructed so as to protect effectually the metal parts from the weather, and to prevent accumulation of dust on the gaps.

6. The gaps in the arrester should be between parallel plates, disks, or rings instead of between cylinders or spheres so as to permit repeated heavy discharges without seriously altering the length of the gaps.

7. The arrester should be constructed so that in the event of the failure of the arrester to interrupt the dynamic arc the enclosing case will be shattered by the heat so as to give some visual evidence of the trouble and result in the opening of the circuit.

8. The arrester should be without moving parts or parts which require inspection, renewal or adjustment and should preferably be made in the form which

cannot be inspected or repaired without removing it from the pole.

The experience with the arresters covered by this investigation indicates that several types of arresters are now available which comply with all of these specifications. The annual maintenance cost has up to the present time averaged well below 1 per cent per annum and is practically confined to the replacing of damaged arresters. It is possible that the present forms of gaps will not permit of an indefinite number of discharges without affecting the protective value of the arresters, but if such a condition should arise it would probably be manifested by an increase in the percentage of transformers burned out by lightning. The condition of the gaps could be determined by emoving from the line and examining and testing the arresters which were protecting transformers that had burned out. The maximum number of arresters to be treated in this manner would be less than 1 per cent of the total number installed and this number in all probability could be considerably reduced by careful investigation of the conditions surrounding their installation along the lines described in the earlier part of this paper, and this would serve to still further reduce the cost.

7. Suggested Future Plans

In Chicago it is the standard practise when making line extensions to install in the center of each block one pole larger and stronger than the others for a future transformer pole. By going over the map of the distribution system it has been found that if additional arresters were installed on these future transformer poles, so that each transformer will be protected not only by an arrester on the same pole but also by additional arresters one block away in each direction along the lines, then the additional arresters required will only be 2 per cent of the total number at present installed for the protection of transformers. Calculations made with the aid of the curves show that these 2 per cent additional arresters will result in a saving of at least 7 per cent of the present number of burn-outs. The installation of these additional arresters would, therefore, appear to be warranted by the reduction in the operating and maintenance charges.

There appears to be a number of locations where submarine cables crossing the river, or lead-covered cables at other locations, connect with the overhead lines at points which are several blocks removed from the nearest transformer and they are, therefore, protected only by an arrester on the cable pole. In such cases it appears that additional arresters would be warranted in the vicinity of such cable terminals, and particularly so in the case of submarine cables and perhaps other special cases where the cost of repairs would be very heavy. In some cases where an overhead line is supplied from a single underground cable, and where there are no arresters on transformers within several blocks of the cable pole, it may be possible by the installation of additional arresters in the vicinity of the cable pole, to save the cost of an emergency supply.

8. Differences between Laboratory Tests and Service Experience

The investigation and the calculations herein described indicate that four types of arresters differing in such details of design as the number of gaps between line and ground, the amount of series resistance, and other features, are so nearly alike that they can be considered as having identical protective value under the conditions of service. The results of the laboratory tests, however, indicate that the arresters are quite appreciably different in their protective value, and up to the present time it has been found impossible to reconcile the results of the laboratory tests with the experience in service. It is suggested, however, that the impedance of the ground wire and of the pipe used as the lightning arrester ground may be sufficiently high to overshadow the differences in the amount of resistance and the number of gaps, and in this way tend to equalize the behavior of different types of arresters under the conditions of service. In view of these differences and of the expense and the time required to determine the relative merits of different types of arresters from the experience in service, it is suggested that it would be very interesting and valuable development in the art if some form of laboratory tests for lightning arresters could be devised whose results would more nearly agree with the results of experience in actual service.

9. Conclusions

The conclusions from the investigations described in this paper, together with the more important conclusions from the previous paper, some of which have been modified and extended by these investigations, may be summarized as follows:

1. Transformer troubles during lightning storms may be reduced (a) by the removal of transformer primary terminal boards, (b) by the installation of lightning arresters, (c) by the use of larger bushings on the primary leads of transformers where they enter the case.

2. Lightning arresters installed on transformer poles are considerably more effective than if installed on the line poles.

3. Even in the most severe lightning storms, which apparently cover the given territory quite completely, there will be numerous extended areas within this territory which will be entirely free from lightning disturbances. Careful records extending over a period of several years are, therefore, necessary in order to determine definitely whether immunity from troubles due to lightning is due to the efficiency of the lightning protection or to the absence of lightning.

4. There is a very marked improvement in the effect of lightning arrester protection with an increase in density, that is, the number per square mile, and this effect is such an important factor in their performance that no accurate comparison of the relative merits of various types of arresters can be made without giving this point proper consideration.

5. Where the number of transformers, each of which is protected by an arrester on the same pole, is large per square mile so that the transformers and arresters are on the average only a few hundred feet apart, the total combined effect of all of the adjacent arresters is greater than that of the arrester on the same pole with the transformer.

6. In districts where transformers are widely scattered, that is, where the local density is materially below 100 per square mile and where continuous service is important, it will probably be found desirable to install arresters on line poles in addition to an arrester on the same pole with each transformer; where the local density is of the order of 50 per square mile, or lower, the installation of such additional arresters will probably be found to be warranted solely by the reduction in operating expenses.

7. The increase in the density of lightning arresters also results in a marked decrease in the percentage of burn-outs due to lightning of underground cables connected to overhead distribution circuits, and while the exact figures for the early years are not available, the percentage has been reduced from several per cent per annum with a very low density to a figure running well below one-tenth of one per cent per annum with the density averaging about 200 per square mile.

8. In the case of high-voltage cables, that is cables operating at voltages ranging up to 25,000, and where the present practise in this country calls for a maximum of one arrester at the point where the underground cable connects with the overhead line, the installation of additional arresters in the vicinity of the cable pole would in all probability cause a marked reduction in the percentage of burn-outs of such cables due to lightning.

9. The effect of density of arresters, of the shielding effect of high buildings, trees, etc., and perhaps also other features, have such an important effect on the amount of trouble from lightning that no accurate comparisons of the results secured in different cities can be made without giving due consideration to all such features of the conditions under which the lightning arresters are installed.

10. For use in the protection of transformers in districts where each transformer is protected by an arrester on the same pole and where the density of arresters ranges above 200 per square mile, the most economical arrester of the several types covered by this investigation is probably the cheapest arrester. It is entirely possible and even probable that the local conditions will have an important bearing in determining the best type of arrester to be used in any given locality, and that where the amount of shielding from buildings, trees, wires of other companies, etc., is very slight and where the securing of adequate ground connections for the arresters is expensive it would be preferable, even in areas of low density, to use arresters whose discharge capacity is considerably greater and whose discharge potential is considerably lower than the arresters covered by these investigations and to confine the installation of the arresters to the transformer poles.

11. It is possible, by carefully distributing the various types of lightning arresters over a large area and by securing the results of the performance of arresters over a period of years, to place the several types of lightning arresters used for the protection of transformers under conditions that are practically identical as regards the features which would affect the relative performance of the various types of lightning arresters, and to secure data which will permit a comparison of the relative merits of the several types of lightning arresters as protective devices.

12. It is entirely possible to make lightning arresters of the self-contained type, that is, of a type not requiring an external protecting box and so constructed as not to require or permit inspection. The annual maintenance cost of such arresters is practically limited to the replacing of damaged arresters, and the total annual maintenance cost as indicated by an experience of five years with several thousand such arresters is well below 1 per cent of their original cost of installation. The adoption of such types of arresters will result in a material reduction in the annual maintenance cost as compared with the older types.

13. A change in the form of lightning arrester gap from a cylindrical or spherical shape to parallel flat surfaces which was adopted by the manufacturers when changing from the wooden box type to the self-contained type of arrester, appears to result in a form of design which allows repeated heavy discharges without requiring renewal or adjustment of the parts, and has been an important factor in changing the design from a type requiring annual inspection, renewal and adjustment to a type which does not permit or require such annual attention.

14. The four types of arresters which have been designated by the letters *C*, *D*, *E* and *F* and which consist essentially of a resistance in series with a number of gaps, together with such additional features as antennas, compression chambers, expulsion chambers, and solenoids to vary the length of the gap following dynamic discharge, all appear to be practically identical in their value as devices to protect line transformers.

15. The type of arrester designated by *B*, which consists of a large number of gaps in series without any resistance, in addition to two other paths through a high and a low resistance shunting a large and a small

number of gaps, appears to be considerably better protective device than arresters designated by C, D, E and F, and as far as can be determined from present information, this difference in its value as protective device appears to be due to features of its design.

16. With the aid of the data contained in this paper it should be possible to make estimates of the cost and results of lightning protection in Chicago with the same degree of accuracy as the estimates of cost of construction or maintenance of overhead lines, when the figures are averaged over a period of years.

17. The shielding effect of high buildings, trees and other similar features which might be considered as determining the exposure of the lines to lightning have an important bearing on the amount of damage that will be caused by lightning. In local areas in a distribution system which have for years shown a high percentage of troubles caused by lightning and where the troubles have been allowed to persist because of the thought that some mysterious influence local to the neighborhood attracted the lightning, it will probably be found that a large percentage of troubles is due to the lack of shielding from the surroundings or a low density of arresters, and that the trouble can be materially reduced by increasing the density of the arresters in the locality.

18. Great caution should be used in attempting to compare the results secured by lightning arrester protection in Chicago with results secured in other localities without giving due consideration to all of the factors which might affect lightning arrester performance.

In conclusion the author desires to express his appreciation to the General Electric Company and the Electric Service Supplies Company for their many helpful suggestions and hearty cooperation during the progress of the investigations.

ENGINEERING COURSES FOR EX-SERVICE MEN

Under the law passed by the last session of Congress, the Federal Board of Vocational Education has made arrangements to give electrical engineering courses at the expense of the Board to a total of 571 disabled ex-service men.

About 800 men are taking the mechanical engineering course and between one and two hundred men the mining engineering course. An effort has been made to choose schools and colleges in every section of the country so that they will be convenient and cover all the fields of engineering work.

There are at present 2387 men taking these engineering courses. Among the institutions being used by the Federal Board for this purpose are: Harvard University, Huntington School (Boston), Columbia University, Carnegie Institute of Technology, Lafayette College, Lehigh University, Pennsylvania State College, University of Pittsburgh, University of West Virginia, Georgia School of Technology, Michigan School of Mines, Rolla School of Mines, Montana School of Mines, South Dakota School of Mines, Colorado School of Mines, New Mexico School of Mines, University of Utah, Stanford University, University of Arizona, University of California, University of Nevada, University of Washington, El Paso School of Mines. These schools are distributed as follows: Nine schools in Massachusetts; five in New York City; five at other points in New York; twelve in Pennsylvania; six in Ohio; six in Illinois; three in Indiana; three in Tennessee; three in Michigan; three in Iowa; three in Kansas; three in Missouri; three in Colorado; ten in California; three in Oklahoma. In addition one or two schools in the following states have been designated: New Hampshire, Vermont, New Jersey, Connecticut, District of Columbia, Maryland, Virginia, Georgia, North Carolina, Alabama, Mississippi, Louisiana, Kentucky, Wisconsin, Nebraska, Minnesota, Montana, New Mexico, Utah, Arizona, Oregon, Washington, and Texas.

FOREIGN AVIATION INSTRUMENTS

Several new instruments, most of them of German manufacture, have been received from the Bureau's representative in Europe, and have been studied carefully with the object of obtaining information concerning the future design of aeronautic instruments in this country. A Bamberg distant compass (a German instrument) has been thoroughly investigated and some very interesting results have been obtained. This compass depends for its operation upon the characteristic of selenium which causes a variation in its electrical resistance with any change in the intensity of illumination falling upon it. The installation is so arranged that the compass itself may be mounted in the tail of the airplane at a distance from all disturbing magnetic influences. The bowl of the compass contains two electric bulbs diametrically opposed which throw their rays through a lens which concentrates them upon two corresponding selenium cells mounted on a bridge extending across the top of the bowl. A metal disk, corresponding to the card of the ordinary compass, is cut in such shape that it acts as a blind for the illuminating elements. Thus the intensity of lighting of the selenium cells is varied in accordance with the position of the magnetic element carrying this disk. By means of a properly arranged electric circuit, the position of the magnetic element is made known to the pilot by the indications of an ammeter suitably calibrated and mounted on the instrument board. The navigator is able to direct the pilot on a desired course by means of an indicator connected mechanically to the compass in such a manner as to make possible the rotation of the bowl at will by the navigator.

Electrostatic Condensers

BY V. E. GOODWIN

General Electric Co., Pittsfield, Mass.

In studying the progress of the electrical art one is continually confronted with the fundamental factors in Ohm's law—namely, volts, amperes, resistance, inductance and capacity. Of all these factors, the least practical use is made of the latter, and one is naturally interested to learn the reason for this apparent neglect when there are so many applications for this factor.

A review of the proceedings of the A. I. E. E. shows many references to the subject of electrostatic capacity or capacitance, but one finds only two papers on the subject of condensers, and one of these appeared over twenty years ago.

The purpose of this paper is to stimulate a more active interest in the development and application of electrostatic condensers. It is well-known that the electric condenser is one of the oldest electrical devices, and the thought naturally comes to mind as to why there has been so little progress made in its development during the past decade or two, during which there have been such rapid strides in other lines of the industry.

The author believes that a review of the subject at this time will tend to stimulate interest and promote a more rapid development in this branch of the art.

The first part of this paper will be confined to fundamental characteristics of condensers and their relations to electric circuits containing inductance and resistance, and includes a discussion of the effects of switching condensers on and off such circuits. The second part of the paper describes some of the more important applications of condensers and illustrates the great demand there is in the electrical industry for this class of apparatus.

SECTION I

An electrostatic condenser acts as a non-conductor or a very high resistance to a constant direct voltage and as a conductor while the voltage is varying. When voltage is applied and current flows, the condenser becomes a source of counter e. m. f. opposing the applied voltage, making the sum of the voltages in the circuit equal to zero. A condenser takes sufficient current so that its counter e. m. f. plus the counter e. m. f. of the series inductance and resistance is equal to the total applied voltage. Similarly, when a charged condenser discharges through a resistance and inductance, the applied voltage of the condenser is equal to the counter e. m. f. of the inductance and resistance. The characteristics of a condenser circuit are thus more or less dependent upon the characteristics of the series resistance and inductance. The above statements apply in general to all electrical insulation. Insulation is used to separate one conductor from another and therefore always forms part of a condenser.

Electrical energy can be stored in two forms, electrostatic and electromagnetic. In condensers energy is stored in the electrostatic form. In inductances energy is stored in the electromagnetic form. Electric energy in process of transfer from one point to another in an electric circuit always exist in both electrostatic and electromagnetic forms.

Both potential and current are necessary for the transmission of electrical energy. Thus, in the condenser, current must flow in order that electrostatic energy may be stored. Potential must exist across an inductance while the current and stored electromagnetic energy are increasing or decreasing. The rate (in watts or joules per sec.) at which energy is passing into or out of a condenser or inductance is equal to the product of volts times amperes.

A condenser stores energy while its voltage is increasing and gives out energy while its voltage is decreasing. An inductance stores energy while the current is increasing and gives out energy while the current is decreasing.

The fundamental equations for a condenser (using instantaneous values) are:

Quantity in coulombs $q = C\,e$ (farads $\times$ volts)

Current in amperes $i = C\,\dfrac{d\,e}{d\,t}$

Power in watts $p = e\,i$

Energy in joules or watt seconds $w = \dfrac{C\,e^2}{2}$

The fundamental equations for an inductance are:

Inductance in henrys $= L$

Potential in volts $e = L\,\dfrac{d\,i}{d\,t}$

Power in watts $p = e\,i$

Energy in joules or watt seconds $w = \dfrac{L\,i^2}{2}$

Oscillation Circuit. When a charged condenser discharges through an inductance the current at any instant is such that the inductance voltage is equal and opposite to the condenser voltage. The current starts at zero and can be zero only when the condenser is fully charged. The current is proportional to the rate of change of condenser voltage. The condenser voltage is equal and opposite to the inductance voltage. The inductance voltage is proportional to the rate of change of current. These conditions can only be met by a current varying according to a sine (or cosine)

To be presented at the Chicago Meeting of the A. I. E. E., November 12, 1920.

wave, the current lagging a quarter cycle behind the condenser voltage and leading a quarter ahead of the inductance voltage. The frequency of the sine wave oscillation is determined by the relations.

$$e = L\frac{di}{dt} = \frac{1}{C}\int i\,dt$$

where $i = I \sin 2\pi f t$

$$\therefore f = \frac{1}{2\pi\sqrt{LC}}$$

The energy then oscillates between the condenser and inductance, being all in the condenser when the current is zero and the voltage maximum, and all in the inductance when the current is maximum and the voltage zero. With the condenser initially charged to a given maximum voltage E, the maximum value of current during discharge is then determined by the relation:

$$1/2\, C E^2 = 1/2\, L C^2$$

$$\therefore I = \frac{A}{\sqrt{L/C}}$$

Such a circuit is called an oscillation circuit. Since there is no loss of energy (except that due to resistance, radiation etc.), it is possible to build up a large oscillation by the addition of a large number of small amounts of energy. For example, a voltage may be induced in the inductance while it is giving energy to the condenser. The building up of an oscillation by a number of large or small increments of energy received at the proper instants is called resonance.

If the oscillation circuit contains a small resistance the oscillation is damped or decreasing in amplitude. The condenser voltage is equal to the inductance voltage plus the resistance voltage. The conditions are then satisfied by a current wave which is the product of a sine curve by a hyperbolic curve.

That is $i = I\, e - \frac{Rc}{2L}$

$$t \sin \frac{1}{2\pi}\sqrt{\frac{1}{Lc} - \frac{R^2}{4L^2}}\quad t$$

This equation does not hold and becomes imaginary if R is equal to or greater than $\sqrt{\frac{4L}{c}}$

If R is equal to or greater than $\sqrt{\frac{4L}{c}}$ the total energy is dissipated in the resistance during one rise and fall of current and there is no oscillation.

If the circuit contains resistance and negligible inductance the current starts at a maximum and decreases to zero along a hyperbolic curve. $- i = I\, e^{-CRt}$

Condenser Connected to D-C. Circuit. When a condenser is switched onto a direct-current circuit containing a resistance R and a negligible amount of inductance, the current transient starts at a maximum and decreases to zero along a hyperbolic curve. If there is inductance in the circuit the current starts at zero and there must be at least one rise and fall of current. If the resistance is less than the critical value $\sqrt{\frac{4L}{c}}$, there will be a damped oscillation of current. If it were possible to have zero resistance, the oscillation would be continuous or undamped.

Condenser Connected to an A-C. Circuit. There are always more or less of current and voltage transients when the condenser is switched on. Any rise of condenser voltage above normal is due to series inductance. If the inductance is relatively small, the rise of voltage will be small as there will not be enough energy stored in the inductance to charge the condenser much above normal. If the inductance is relatively small, the current transient will be much larger (in per cent of normal) than the voltage transient. The energy of the transients is dissipated in the series resistance so that the current and voltage soon come to their normal values.

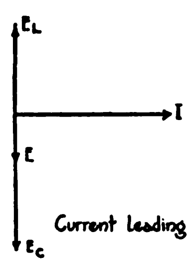

Fig. 1

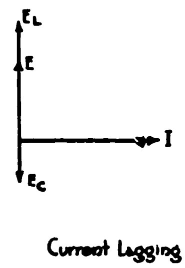

Fig. 2

The normal value of current is determined by the relation that the current is equal to the capacitance times the rate of change of voltage. The condenser current is proportional to and in phase with the rate of change of voltage. In the case of sine waves, the rate of change of voltage has the same wave shape as the voltage wave and a proportional maximum value, but passes through its maximum value a quarter cycle before the voltage wave. The rate of change of voltage at any instant is equal to $2\pi f$ times the voltage value which will exist a quarter cycle later. It is, therefore, permissible to say that the condenser current is proportional to the voltage but leads the voltage by a quarter cycle. This statement is true only for sine waves, but is generally used because commercial waves are approximately sine waves. It should be kept in mind that the fundamental fact is that condenser current at any instant is proportional to the rate of change of voltage at that instant. As usually stated, the current is proportional to and lags a quarter of a cycle behind the applied voltage.

When a condenser is in series with an inductance and the same sine-wave current passes through each, the inductance voltage is opposite in phase to the

condenser voltage and their difference is equal to the total applied voltage.

These relations are shown in the diagrams Figs. 1 and 2.

It is thus possible to raise the voltage and current of a condenser by a series inductance or to raise the voltage and current of an inductance by a series condenser. The current is leading if the condensive reactance is greater and lagging if the inductive reactance is greater. This depends upon the frequency as well as the capacitance and inductance. If the inductive reactance is equal to the condensive reactance the current is limited only by resistance and other losses. This is the condition of resonance. With a given capacitance and inductance, resonance can be obtained by varying the frequency. At a given frequency, resonance can be obtained by varying the capacitance or inductance. The condition for resonance is that $f = \dfrac{1}{2\pi\sqrt{LC}}$

When a condenser is connected in parallel with an inductance, the current and voltage relations are as shown in diagrams Figs. 3 and 4.

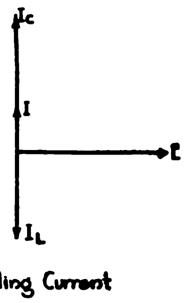

Fig. 3

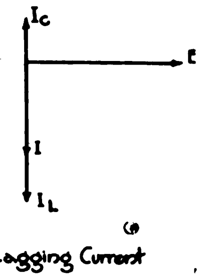

Fig. 4

As in the series connection, the line current may be made lagging or leading by varying the inductance, capacitance, or frequency. When the inductive reactance is equal to the condensive reactance, the current is purely a circulating current in the parallel connection and no current is taken from the line. It is thus possible to reduce the line current to an inductance by connecting a condenser in multiple and vice versa.

In the case of complex circuits containing capacitance, inductance, and resistance there are an unlimited number of possible combinations and each must be considered individually as met with. One such circuit which is of considerable theoretical interest is that of a condenser and inductance or equal reactance in series and a resistance in multiple with either inductance or condenser as shown in Fig. 5.

The vector diagram is given in Fig. 6.

From this diagram it is evident that the voltage applied to the condenser can be divided into two vectors, one of which is equal to and opposite the voltage applied to the inductance and resistance, and the other is in phase with I_L and equal to $X_C\, I_R$. This latter component is the total applied voltage E for any value of R. Similar relations hold when the resistance is connected in multiple with the condenser. $\therefore\ I_R = E/X =$ constant for any value of R. This circuit, therefore, gives a means of obtaining constant current from constant sine-wave voltage. There are a number of other more complicated circuits

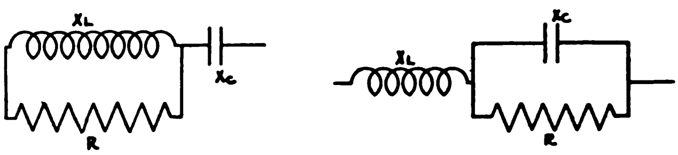

Fig. 5

giving the same results. These circuits have been known for many years but up to the present time have been considered only of theoretical interest. (For a complete treatment of these circuits, see Steinmetz' Theory and Calculation of Electrical Circuits.)

Distributed Capacitance. The foregoing discussion has referred only to a concentrated capacitance; that is, to a capacitance having a negligible inductance within itself. The usual forms of commercial condensers can for all practical purposes be regarded as concentrated. At low frequencies the capacitance of cables and transmission lines may be considered as made up of one or several concentrated capacitances. At high frequencies, transmission lines and cables must be treated as distributed capacitances and distributed inductances. High frequencies or high rates of change of voltage occur in the case of sudden changes of circuit conditions which set up traveling waves in transmission lines. It is principally in the phenomena and theory of traveling waves that the action of transmission lines as distributed capacitance and inductance becomes of importance.

Traveling waves are usually considered as having vertical wave fronts. This assumption is justified by the fact that it greatly simplifies calculations and because a vertical wave front is the limiting condition, and the effects calculated on that basis will mark the

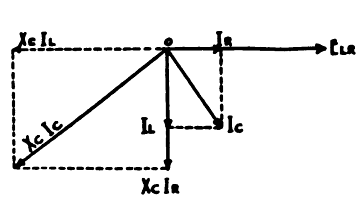

Fig. 6

maximum limit of any effects which could occur in practise.

One of the fundamental characteristics of a traveling wave is that the total energy is equally divided between electrostatic and electromagnetic energy. This fact is expressed by the equation

$$1/2\, C\, E^2 = 1/2\, L\, I^2$$

This equation follows directly from the fundamental equations:

$$Q = C E = I t.$$

$$\therefore \frac{C E^2}{2} = \frac{E I t}{2} = \frac{1}{2}\text{ total energy.}$$

$$\therefore \frac{L I^2}{2} = \text{other } \frac{1}{2} \text{ “ “}$$

It also follows directly from the above equations that

$$E = I \sqrt{L/C} = I Z$$

where Z = the "surge impedance."

Another fundamental characteristic of an electric wave is that the voltage is doubled when striking a point of total reflection. At reflection the length of the wave is reduced by one half and the energy is all electrostatic. The electrostatic energy per unit of length is thus four times as great and the voltage twice as great as in the traveling wave.

When a traveling wave strikes a point of short circuit, the current doubles and the voltage reduces to zero during reflection.

SECTION II

The characteristics of condensers as outlined in Section I give them a wide field of application in electric circuits. In the following, an attempt will be made to discuss the more common and practical of these applications.

1. *Telephone Service.* In telephone circuits, it is often necessary to confine the flow of direct current to certain sections of a network of conductors and at the same time to allow alternating and pulsating currents to flow as desired. This separation is accomplished by means of condensers connected in series with the line at the limits of the d-c. zones. Thus it is possible to use alternating currents to call inactive stations and to separate the minute pulsating talking currents from the relatively heavy direct currents. The condenser in this service not only economizes in the amount of energy required, but also makes long distance telephony possible.

It is also interesting to mention the fact that specially constructed condensers can be used as telephone receivers. A condenser of this construction is known as the "singing" condenser as it will produce audible notes corresponding to the rates of change of the applied voltage impulses.

2. *Condensers in Oscillating Circuits.* The condenser finds a wide application in oscillating circuits where it is desired to produce high-frequency voltages or to study the effects of impulses having steep wave fronts.

Oscillating circuits are of two general types, known as the oscillation generator and the oscillation transformer. Fig. 7 shows the diagrammatic arrangement of the oscillation generator.

The purpose of this machine is to produce an impulse or train of oscillations of definite wave form whenever the alternator voltage is raised sufficiently to spark over the gap G. These machines have been of great value in studying the action of exceedingly high rates of change in potential and in the study and determination of the dielectric spark lag of insulating materials.

Fig. 8 shows circuit connections of the oscillation transformer.

The application of this form of apparatus is in the production of recurrent oscillation at high frequency and voltage. By varying the adjustable inductance L

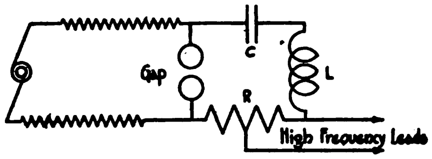

FIG. 7

and capacitance C, it is possible to obtain any desired frequency. By varying the ratio of the turns in the air transformer T, it is possible to obtain a wide variation in voltage of the high-frequency oscillation. This circuit is used extensively in wireless work, as will be described later, and in many forms of testing and laboratory work.

3. *Protection from Lightning and High-Frequency Disturbances.* The fact that a condenser stores energy as the voltage increases, and gives out energy as the voltage decreases, can be made use of in protecting electric circuits from abnormal disturbances having steep wave fronts. When a steep wave impulse reaches a point in the circuit where a suitable condenser is connected across the circuit, it delivers a steepness of wave form or rate of change of potential. The amount of energy

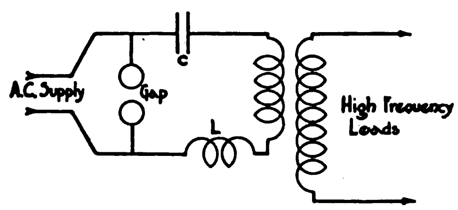

FIG. 8

delivered depends upon the voltage of the impulse and the capacitance of the condenser. This tends to make the wave front more sloping and less dangerous and also tends to lower its maximum potential in cases where the crest of the wave is short. When the impulse passes, its potential starts to decrease in what is known as the rear, or tail of the wave. The condenser then gives its energy back into the impulse, modifying the shape of the rear of the wave by making it likewise more sloping.

Another and more common, application of condensers for protection purposes is in the absorption and consequent elimination of high frequency. This applica-

tion is based upon the fact that the current flow in a condenser is proportional to the rate of change of potential and in the case of a recurrent oscillation to the frequency. The absorption is accomplished by inserting a resistance in series with the condenser. The value of resistance for maximum absorption with a given condenser is obtained when $R = \frac{1}{2\,\pi\,f\,C}$. The value of capacitance to be used should depend upon the nature and character of the oscillations which are to be handled by the machine. In actual practise these oscillations vary through a wide range in frequency and voltage. The actual designs of these machines employ a capacitance, for a given operating voltage, such as to allow a normal current from 0.05 to 0.10 ampere to flow at 60 cycles. Under normal conditions little energy is absorbed from the system. If, however, an abnormal recurrent disturbance is started by an arcing ground or other cause, the condenser, with its series resistance, acts like a valve operated by the frequency and allows more and more current to flow through the resistance as the frequency increases.

The impedance of a condenser with a series resistance is

$$Z = \sqrt{R^2 + \left(\frac{1}{2\,\pi\,f\,C}\right)^2}$$

Assuming R = 100 ohms, C = 0.01 microfarad
f = 60 cycles and E = 13,200 volts.
Then Z = 265,000 ohms.

At 13,200 volts the current at 60 cycles would be 0.05 ampere and the energy absorbed per second by

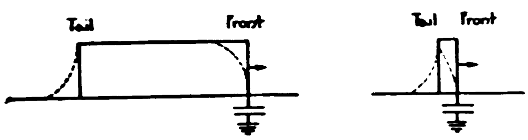

FIG. 9

the series resistance would be $0.05^2 \times 100 = 0.25$ watt-seconds.

If the frequency is 100,000 cycles,
Then Z = 188 ohms.

At 13,200 volts the current at 100,000 cycles would be 70.3 amperes and the energy absorbed per second $70.3^2 \times 100 = 494$ kilowatt-seconds.

From the above, it will be seen that at low frequencies the major part of the impedance is in the condenser while at 100,000 cycles the principal impedance is in the resistance R. The above calculations are based upon the resistance and capacitance remaining constant at all frequencies. This is not exactly true in practise as the capacitance of condensers and the conductance of resistance decreases as the frequency increases. This is due to the absorption factor of dielectrics and the skin effect and temperature coefficient of resistances. These are variable factors depending upon the shape and character of the materials used. With proper designs these factors should not have much effect at frequencies below 100,000 cycles.

Since many abnormal disturbances in electric circuits are of an oscillatory nature and have relatively little energy back of them, it would seem that an absorber of this character would prove an excellent protector, as its ability to absorb and consequently destroy oscillations increases so rapidly with the frequency and destructiveness of oscillations.

Another use of condensers as a protective device is in connection with what has been termed a resonant shunt. With this apparatus the condenser is connected in series with an inductance which is tuned to resonance for a given frequency. Oftentimes in electric circuits, it is found that there is present a certain harmonic or superimposed oscillation of a definite frequency which is detrimental to the operation of other apparatus at some point in the circuit. By connecting a resonant shunt across the circuit and having it tuned to the particular frequency of the undesirable harmonic will provide a short-circuit path which will entirely eliminate this undesirable part of the wave form and leave the fundamental wave unchanged. This combination should have a wide field of application particularly in eliminating such harmonics as are liable to produce telephone interferences.

A further application of condensers as a protective device would be to shunt series coils on regulators, current transformers, etc. These series coils being connected in the line will subject them to high rises of potential between turns whenever a traveling oscillation passes through them. By providing a shunt path consisting of condensers of such capacity as to allow little current to pass at normal frequency, it would be possible to shunt the major part of the high frequency disturbance through the condenser and thus prevent a rise of potential between turns and between the terminals of the series coil and thus relieve the strain on the insulation.

4. *Power Factor Correction and Improvement in Line Regulation.* Static condensers have a power factor of approximately 0.003 leading and an energy of loss of less than 0.5 per cent. For practical purposes, we can consider the power factor as zero leading as it is extremely difficult to measure even with the most sensitive galvanometers. In alternating current power service, it is therefore possible to apply static condensers to correct low power factors resulting from lagging currents.

Power factor corrections can be accomplished by either of two methods: First by retarding the voltage vector so that it becomes more nearly in phase with the current; and second, by advancing the current vector so that it becomes more nearly in phase with the voltage. The former scheme can be accomplished by the use of a

suitable condenser in series with the load, and the latter by means of a condenser in shunt with the load.

The problem of power factor correction has been quite fully discussed before the Institute in connection with synchronous condensers so it will be unnecessary at this time to point out the advantages accruing therefrom. The electrostatic condenser has, however, certain advantages over the synchronous type for certain classes of work and should find a wider application when their adaptability for this service is more fully understood. The following are some of the advantages of the electrostatic condenser for power work:

1. Being a stationary apparatus, no attention is required.
2. The high efficiency of the outfit means that the annual power loss is very small.
3. With reliable condensers the maintenance costs are practically nil.
4. The corrective kv-a. can easily be increased or decreased by simply cutting in or out of sections.

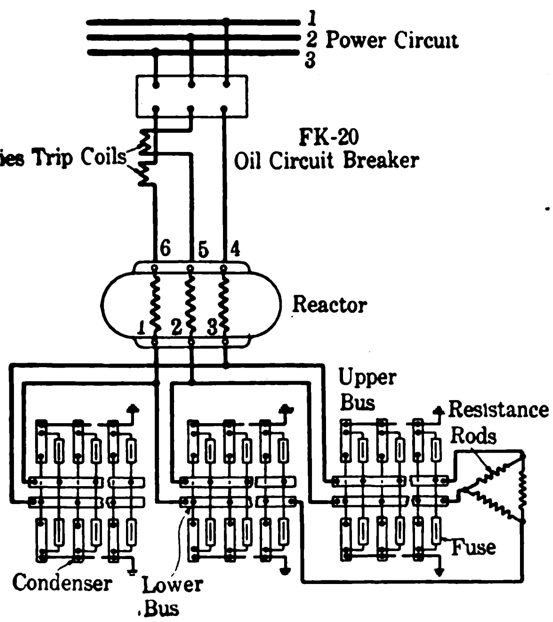

FIG. 10

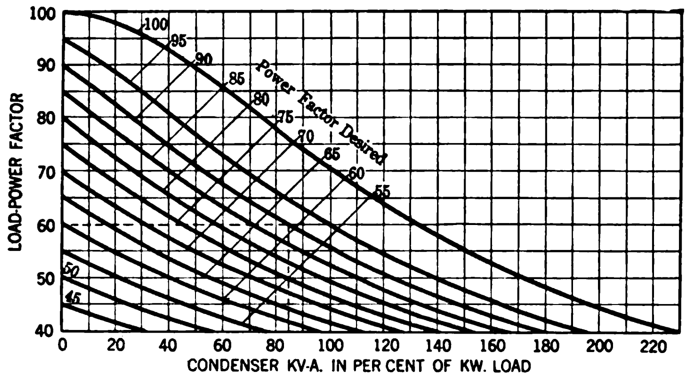
5. The outfit can be connected to any part of the system and thus provide correction at the points where the greatest saving can result.
6. Noiseless and requires no special foundation.
7. Lower first cost for small installations.
8. It can also be used to improve the line regulation.

Fig 10 shows the diagrammatic connections of a static condenser used for power factor correction on a 2300-volt, three-phase circuit.

The condensers are connected in delta and each phase is divided into a number of sections each having a suitable enclosed fuse in series. A low reactance is connected in each phase between the circuit breaker and the condensers to act as a harmonic screen. This reactance can also be used to boost the voltage on the condensers so as to obtain greater corrective kv-a. with a given condenser. High resistances are connected in parallel with each phase of the condensers to discharge the condensers when they are disconnected from the line.



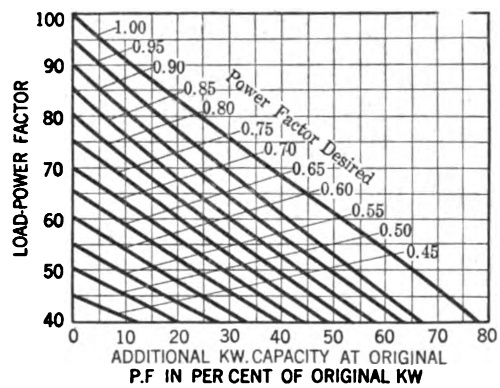
CURVE SHEET I—DETERMINATION OF CONDENSER CAPACITY REQUIRED FOR CORRECTING THE POWER FACTOR OF AN A-C. CIRCUIT

Follow horizontal line corresponding to present power factor of load until it intersects curve representing power factor desired. The vertical projection of this intersection on the base gives the size of condenser required in per cent of kw. load.

Example: Load 250 kw. Present power factor 60 per cent. Power factor desired 90 per cent.

Projection of intersection of 60 per cent power factor line with 90 per cent power factor curve gives desired condenser as 84.9 per cent of 250 kw. or 210 kv-a.

In studying the application of condensers for power factor work the author has found it more convenient to



CURVE SHEET II—DETERMINATION OF ADDITIONAL CAPACITY MADE AVAILABLE BY THE INSTALLATION OF STATIC CONDENSERS

Follow horizontal line corresponding to present power factor of load until it intersects curve representing power factor desired. The vertical projection of this intersection on the base gives the per cent of the original kw. load at the original power factor made available by the condenser.

Example: Load 250 kw Present power factor 60 per cent. Power factor desired 90 per cent.

Projection of intersection of 60 per cent factor line with 90 per cent power factor curve gives kw. load at 60 per cent power factor made available as 35 8 per cent of 250 kw. or 89.5 kw.

rate these units in terms of kv-a. at their rated voltage rather than in terms of capacitance.

If a sine wave of voltage E at a frequency f is impressed on a condenser section of capacity C farads, the current $I = 2 \pi f G E$

The leading kv-a. is $E I \times 10^{-3}$.

Hence, kv-a. $= 2 \pi f C E^2 \times 10^{-3}$.

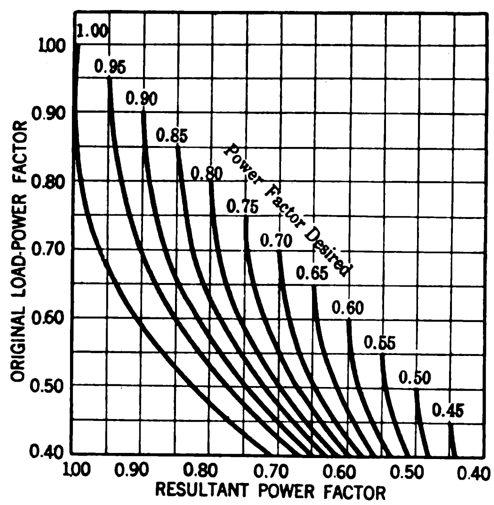
If C is expressed in terms of microfarads,

$$\text{kv-a.} = 2\,\pi\,f\,C\,E^2 \times 10^{-9}.$$

In the determination of the size of static condenser equipment required to correct the power factor of a given load, curve sheets I, II and III will prove of value. Curve sheet I gives the kv-a. correction required in percentage of the kw. load for any desired improvement in power factor from 40 per cent to 100 per cent.

In studying a problem of this character, the question naturally comes up as to how much additional load can be added at the original power factor after a certain correction has been added. These data are shown by curve sheet II.

Curve II indicates the amount of load at the original power factor that can be taken on a feeder, after correction has been added, without exceeding the initial heating in the lines and apparatus.



Curve Sheet III—Determination of Resultant Power Factor After Original Load at Corrected Power Factor has Been Increased by Additional Load at Original Power Factor so that the Total Kv-a. of the Circuit is Equal to the Original Kv-a.

Follow horizontal line corresponding to original power factor until it intersects curve corresponding to the corrected power factor. The projection of this intersection on the base gives the resultant power factor.

Example: A load of 250 kw. having a power factor of 60 per cent is raised to 90 per cent power factor by the installation of a static condenser.

A load of 89.5 kw. at 60 per cent power factor corresponding to the additional capacity made available by the correction in power factor is added so that the total kv-a. is equal to the original kv-a. The resultant power factor is obtained by projecting the intersection of the 60 per cent power factor line with the 90 per cent power factor curve upon the base and is found to be 81.5 per cent.

After the additional load indicated by Curve II has been taken on, it is desired to know the resulting power factor. These values are shown on curve sheet III. By the use of these three curve sheets, practically any information relative to loads and power factors can be quickly determined.

The static condenser is not necessarily a competitor of the synchronous condenser, since its principal application is in a field which has never been open to the latter machine.

During the past few years, there has been a gradual awakening throughout this country to the inefficiency of distribution networks resulting from low power factors. Operating companies, with a view to fairness to their customers, have added power factor clauses to their power contracts penalizing customers for low power factors. In other words, they aim to charge each customer for the delivery of his wattless or reactive load in addition to his energy load. This policy has opened up a new field for power factor correction which includes a large number of relatively small loads for which the stationary, or static condenser is particularly suited.

In the design of condenser sections the question of reliablity is of greatest importance. On the other hand, it is necessary to employ a dielectric of high permitivity. This dielectric must be very uniform throughout its entire volume. These conditions are very difficult to meet with very thin sheets even with modern insulations. It is therefore necessary to build up the dielectric of a condenser from several very thin sheets in order to obtain reliability. It has also been noted that as the number of sheets increased it becomes more difficult to radiate the heat. By studying these opposing factors for a given dielectric, we can arrive at a construction giving the most economic design. This gives a condenser which can be operated at any voltage up to its maximum reliable rating.

Since the kv-a. rating of a condenser increases as the square of the impressed voltage, operation at voltages less than normal results in reduced capacity. Hence, when considering a static condenser outfit for operating at voltages less than normal, it is often more economical to use a transformer to step up the voltage rather than to employ a greater number of condenser sections.

Another method of raising the voltage on a condenser is to install a suitable series reactance, but in doing so, care must be taken to avoid resonance.

5. *Electric Welding.* It is worthy of note in passing that reliable electric welding can be done with a circuit containing considerable capacitance. Preliminary work along this line indicates that equally good work can be done with circuits containing either inductance or capacitance, provided the power factor is of the correct low value. This low power factor is objectionable from the power supply standpoint. If, however, we divide our welding circuits into two groups, one using the condensive circuit and the other using the inductive circuit, it is possible to obtain unity power factor in the supply circuit.

Another application of the condenser to electric welding is based upon the fact that it is possible to charge a condenser slowly and to discharge it at a high ampere rate. This scheme is used quite extensively where small wires are to be welded together. By this means a definite amount of energy can be put into a welding and very uniform results obtained.

6. *Motor Application and Contact Sparking.* As previously shown, the phase relationship of current

to applied voltage depends upon the capacitance inductance and resistance in the receiving circuit. It is, therefore, possible with two or more receiving circuits to obtain two or more currents of different phase relationships from one supply circuit. This process is called phase splitting. These out-of-phase currents may be used to obtain starting torques or to change the running characteristics of single-phase motors. This method of starting gives better running efficiency than other methods for small single-phase motors such as fan motors, and there seem to be considerable possibilities for future developments in such uses for condensers.

A condenser may be used across the interrupter of an induction coil to eliminate sparking and consequent pitting of contacts and to increase the secondary voltages. The smaller the condenser, the greater the secondary voltage, provided there is no sparking at contacts. The smallest condenser which will eliminate sparking should be used. The formula for secondary voltage is

$$E_s = \frac{N_s}{N_p}\sqrt{\frac{L}{C}}\, I_b$$

where I_b = secondary current at break. In other cases condensers may be used merely to eliminate sparking.

7. *Laboratory Testing.* In the electrical testing laboratory, the uses for condensers may be divided into two general classes. The first class involves the condenser as a standard of capacity which may be either absolute, in which the capacity is capable of calculation from measurements of length, or comparison standard, which for convenience is used in the ordinary determination of the value of an unknown capacity. The usual comparison standard condensers employ either air or a very high grade of mica as dielectric. A well designed air condenser has the advantages of practically no absorption and the nearest approach to zero phase difference that can conveniently be obtained. It is, however, very bulky when a capacity of considerable magnitude is desired. The mica standard on the other hand, has an appreciable absorption and phase difference but can be constructed for capacities of several microfarads without becoming exceedingly bulky.

The second class of uses involves the condenser as an auxiliary piece of apparatus by the aid of which it is possible to obtain alternating currents of high frequency, to modify wave forms, and to duplicate and study in the laboratory many of the effects produced by atmospheric electric disturbances.

WESTERN ELECTRIC OFFERS NEW EDUCATIONAL ADVANTAGES TO ITS PERSONNEL

The opportunity to pursue part-time postgraduate studies at Columbia University is offered by the Western Electric Company to the members of its engineering department. Twelve employees will be selected to study for the degree of Master of Arts. These will be in addition to the other educational advantages which were started by the big telephone manufacturers at Columbia last fall.

Candidates for the new course must be employees who hold the degrees of Bachelor of Arts, Bachelor of Science, Bachelor of Philosophy, or an equivalent degree in engineering based on a four-year course of study in an institution whose academic standing is approved by the faculty of Columbia. The minimum academic preparation must include a year's course in calculus, a year's course in general physics and laboratory work, and a year's study in mechanics, optics, heat, electricity or equivalent engineering subjects.

The selection of the candidates will be based on evidences of their present attainments and the promise they have displayed in scientific work. Due regard will be given to the prospective ability of the candidate to employ further training to advantage in his duties with the Western Electric Company. Aspirants whose applications are not granted now may apply for future vacancies at Columbia.

The working hours in the offices and laboratories of the Western Electric Company will be adjusted to permit attendance at all the regular exercises of the university.

BRITISH RAILWAY ELECTRIFICATION

A Committee was appointed in March last by the Minister of Transport of Great Britain to advise what regulations are necessary to ensure that the future electrification of the railways in this country is carried out to the best advantage, more particularly as regards uniformity of equipment. The committee has issued an interim report which recommends that regulations should be issued in accordance with the following conditions:

1. That in the case of those railways which have not as yet electrified any lines, as well as those which at present have electrified all or part of their lines on a direct-current system, their electrification, or extended electrification, as the case may be, should be carried out on the direct-current system.

2. That the standard pressure of the direct-current system at the substation busbars shall be 1500 volts, subject to (*a*) the continuance of any existing 600-volt or 1200-volt installations, and subject to the approval of the Minister of their extension. (*b*) The adoption of half the standard voltage—750 volts—in those cases where it can be shown to the satisfaction of the Minister that advantage would arise from the use of this lower pressure. (*c*) The adoption of higher pressures—limited to a multiple of the standard pressure—where it can be shown to the satisfaction of the Minister that sufficient advantage would accrue.

3. That both overhead and rail conductor collection should be permitted, as long as the position and general design of the conductors and structures are

in accordance with recommendations which will be made in a subsequent report.

4. That the generation of current for direct-current lines should be alternating three-phase at such voltage as may be desirable in each case.

5. That in the case of existing generating stations supplying at any frequency between 25 and 50 cycles, it is unnecessary to make any change in frequency, but that it is desirable that where any one such frequency is in general use in a particular electricity district, any new power station put down in that district for supplying a railway should adopt the frequency which has been approved by the Electricity Commissioners or is in general use in that district.

Commenting on the subject of railway electrifications in Great Britain, *The Engineer*, London, says:

"Because of the lack of definite conclusions, railway electrification in this country has drifted into a somewhat unsatisfactory state. There are direct-current lines working at various voltages and single-phase lines. There are also three-phase alternating plants working at various periodicities. The introduction of a standard periodicity for all the electric railways would involve scrapping much converting plant. Assuming, for example, that the low-pressure direct-current railways are still to be worked at 600 volts, but that the supply periodicity is to be raised to 50 cycles in all cases, then new rotary converters would be needed on all the railways and tramways at present worked with 25-cycle current. There is nevertheless much to be said for the standardization of 50-cycle three-phase generators, and there is no real objection to the new super-power stations containing such machines, provided the railway companies are permitted to generate or obtain from existing stations the most suitable current for working their trains. A periodicity of 16 cycles per second is the best for single-phase traction, but 25-cycle current also gives good results. Many 25-cycle stations already in operation might be used for working single-phase lines. It remains to be shown whether any particular electrification system is good for all railways. When the matter is thoroughly investigated it may easily be found that although the so-called high-tension direct-current system would in many cases give excellent results, in other instances the alternating system would be very much better. Standardization is no doubt in many ways a good thing, but it is difficult to see how it can now be applied profitably to British railway electrification."

AIRCRAFT STANDARDIZATION

Acting upon a request from the Secretary of the International Aircraft Standards Commission, that arrangements be made, if possible, for American participation in the next meeting of the Commission, the American Engineering Standards Committee invited the various government and industrial organizations interested in aircraft standardization, to send representatives to a conference to discuss the question. The conference, which was held in Washington on August 11th, was attended by representatives of the Departments of War, Navy, Post Office, Commerce, and Agriculture, the National Advisory Committee for Aeronautics, the Society of Automotive Engineers, Manufacturers Aircraft Association, American Society of Mechanical Engineers and the American Society for Testing Materials.

It was the unanimous view of the conference that there should be American participation. A committee was appointed to present the matter to the President through the Chairman of the Council of National Defense. As a result, the President addressed a letter to the National Advisory Committee for Aeronautics requesting it to arrange for the presence of American representatives at the conference. The National Advisory Committee for Aeronautics is taking steps to provide such representation.

THE CHAMBERLAIN ROAD BILL

Interested organizations, especially the American Association of State Highway Officials, are now showing active interest in the Chamberlain bill, which it will be recalled proposed an appropriation of $400,000,000 for the continuation of Federal aid to the rural post roads program. This appropriation according to the terms of the bill is to be made available for construction work at the beginning of the fiscal year June 30, 1922. $100,000,000 is available during each of the four years subsequent to this date.

The Chamberlain bill provided that special attention and preference is to be given to the projects that will expedite the completion of an extensive National highway system which is to be inter-connecting at the state boundaries.

In general, the Chamberlain bill carries the provision under which the present Federal aid road act is operating. The Chamberlain bill also proposes to make provision for the public land states as follows: "In each state in which the precentage of total land area to which the title of the United States is unqualified, exceeds ten per cent of the total area of all lands in the State, the Secretary of Agriculture may reduce the ratio of co-operation required, but not to below one-half that which the total of the patented land and national forest land bears to the total area of all lands in the state." A separate fund is also provided for the National Forest roads and trails.

The advisory highway board appointed by the Secretary of Agriculture, a part of the membership of which is composed of state highway officers, has had a number of informal meetings in Washington for general discussion of highway problems. It is understood that they have been considering the terms and merits of the Chamberlain bill.

The Relation of Radiant Energy to Matter, Space and Time*

BY J. D. ROSS

Supt. of Lighting, Seattle

THE first part of the paper, after a short history of the science of light, is devoted to a series of experiments showing unassailable facts, and the writer has then drawn his own conclusions and presented his own theories on interatomic force. Very long light waves were first investigated with the hope of showing by analogy the mechanism of ordinary visible light and of heat.

Light is here understood to consist of, and include all transverse vibrations in the so-called ether, visible and invisible, and therefore includes electrical waves, ultra violet, X-rays and gamma rays.

The writer has found the field that his experiments have opened up to be so vast that the paper is very long. Its principal features are touched on in the following abstract.

A short history of the science of light is first given to show the conceptions of various scientists.

Very long light waves were first studied. The first experiments were on reflection, the writer believing it absurd to think of a light beam as simply bouncing off the surface of a mirror without some intermediate transformation of energy equivalent to the storing of energy in potential form with subsequent release to the kinetic energy of the reflected beam.

This action would be equivalent to the recoil of a spring. The simple idea of motion of atoms or molecules in this action seems impossible for various reasons. It is also untenable in the kinetic theory of heat and for instance in accounting for the selective absorption, transmission and radiation of heat and light waves where millions of atoms are affected by a simple way.

If we revolutionize our whole idea of matter, carrier of energy and consider it only an obstruction and if we consider the energy in matter as potential or latent while the energy in interspace is the real thing to consider we will get nearer the truth. We will then think of matter as the rocks and logs in a rushing torrent that tosses them from place to place as it sweeps forward.

The reflection of light is one of its most fascinating branches and one that has been left severely alone.

In the past years Sir Isaac Newton and Dr. Einstein have both claimed that light does not travel in waves but is projected through space. They are members of a good-sized school. Others like Faraday and Maxwell cling to the theory of a medium in space, across which waves or strains could travel. Faraday in his marvelous work had that mysterious intuition which American slang call a "hunch" and he was generally correct.

In combating the wave theory of light Newton said,

> To me the fundamental supposition itself seems impossible, namely that the waves or vibrations of any fluid, can, like the rays of light be propagated in straight lines without a continual and very extravagant bending and spreading every way into the quiescent medium where they are terminated by it. I mistake if there be not both experiment and demonstration to the contrary.

This quotation is particularly striking when read in the light of the following experiments.

The situation today is beautifully summed up by G. W. C. Kaye in his book, X-rays, page 248 where he says after a discussion of the pulse theories of Stokes and J. J. Thomson and of Planck's quantum theory,

> The difficulties conspicuous with the X-rays have merged into those which all classes of electromagnetic wave are found to present in greater or less degree and the full secret of the nature of X-rays will doubtless be revealed, when we find the key to the overshadowing problem of the mechanism of radiation in general. We have seen that the problem of the transference of energy by ether waves involves us in the conception of a "quantum" of energy, radiation traveling undissipated through space. The reconciliation of the idea with the older and well founded conception of spreading waves remains. The experimental evidence seems to indicate that both theories are true simultaneously, that radiant energy is both concentrated and indivisible and at the same time spreads and is divisible.
>
> The keynote of the old mechanics is in fact continuity; of the new mechanics, discontinuity. Any hope of a compromise between the two theories appears to involve concessions fatal to ether. We are left confronted with the riddle of modern physics.

In the search for evidence of the theory propounded in this paper, the first law considered was: A magnetic line of force cannot pierce a closed circuit without being absorbed as an electric current,—what then? The induced current will be affected by resistance, inductance and capacity. But resistance causes a loss. What if that resistance be made negligible? Where will the energy go? How will it escape? Here seemed to be the secret of reflection.

The writer attempted to reflect 60-cycle waves in line with these thoughts. There are 60 waves per second and they travel 186,000 miles in that time. They are therefore 3100 miles long.

Hertz used prisms and mirrors 6 ft. 6 in. high for his shortest waves of only a few feet in length. The writer attempted to reflect the power from the closed core of a 60-cycle transformer by using only a heavy aluminum ring as a short-circuited coil of one turn set at 45 deg. This ring weighed four pounds and was 10 in. in diameter with a 6 in. hole so that it could tilt

---

Abstract of a paper to be presented at a meeting of the Seattle Section, A. I. E. E., November 16, 1920.

at any angle on the 2-in. by 2-in. core. A magnetic density of 50,000 to 100,000 lines was used.

The experiment was a perfect success. It spoke volumes in an unmistakable message. "This was the basis of the reflection of light." As Keats said "Then felt I like some watcher of the skies when a new planet swims into his ken."

It meant that a light wave traveled with the electromagnetic line head on, *i. e.* in the direction of propagation of a light wave, and that these waves at least were curved sharply in greater and greater sweeps with the distance and they were not straight, but were nevertheless light waves. They were the waves such as Newton said were needed before he would believe that light was not corpuscular, waves with "a continual and very extravagant bending and spreading every way into the quiescent medium where they are terminated by it," and this was the "experiment and demonstration," not "to the contrary" as he predicted, but confirming the existence of a medium in space more firmly than ever.

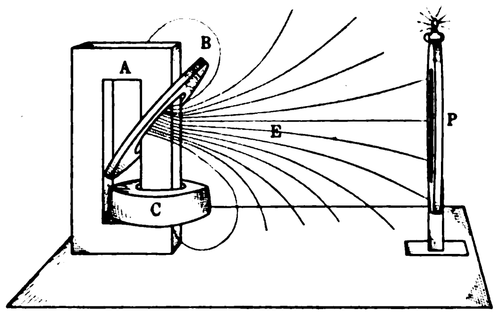


FIG. 1—REFLECTION OF LINES FROM A 60-CYCLE TRANSFORMER

A—Laminated steel core.
B—Ring mirror.
C—Exciting coil.
D—Exploring coil and lamp.
E—Magnetic or light wave.

These waves obeyed Oersted's law, much the same as we use in hydraulics for the flow in pipes, or for any flow or strain. The angles of incidence and reflection of the beam are equal as nearly as is compatible with Oersted's law.

It became plain that light goes from Oersted's law of distribution to the well-known law of inverse squares as the frequency rises as if inertia plays its part and the waves change from currents washing back and forth, to rapid beats on the ether. True vibratory waves are then formed.

The fact that magnetic materials carry long light waves 1000 or 1500 times better than free space pointed to a tremendous resistance to the trasmission of light in free space, just as light is retarded in passing through glass, and it pointed to a higher speed of light than 186,000 miles per second for long waves along iron. The iron acts as a core much as a copper wire acts as guide to an electric wave. It may however be more reasonable to suppose that these waves travel much slower than vibrating visible light, but become faster along iron and thus approach the speed of short rays in space.

Reflection need not take place on matter at all. A pencil of long light waves may strike a plane in free space and reflect on it without the presence of matter provided that such a plane is bounded by a closed circuit. The lower the frequency the more massive must be our mirror. We can reflect magnetic lines out of the core or after they have left the end of a bar magnet just as well with the frame of the mirror after it is removed as we can with the mirror itself providing the frame is metal or lined with metal making a closed circuit. Good conductors must be good reflectors because the efficiency of reflectors depends on electric conductivity.

Conduction of heat now becomes little different from radiant heat except that the ray is retarded as it passes through matter by successive absorptions as electric current and subsequent discharge as the reflected beam, *i. e.* as new lines of force. Good conductors of electricity must also be good conductors of heat, which is the case. Selective absorption and radiation show paths of characteristic length and a structure tending to aggregations larger than the molecule. The violent motion of molecules under heat and the so called Brownean movements of suspended particles are an effect and not the cause of heat or heat itself as we have thought.

Their motion is due to the repulsion of light which in turn is the same as the repulsion of currents out of phase as shown in the well-known repulsion effects of induced currents by Professor Elihu Thomson. In the reflection experiment above described it is difficult to hold the ring mirror in place due to the great repulsion. Heat is not carried by motion of molecules. They need not move at all. It is the alternate unloading of the heat wave or lines of force into an electric current and vice versa until the energy gets away at the surface, *i. e.* it is repeated reflection. Good conductors of electricity must be good conductors of heat.

The molecules are torn asunder if the energy becomes intense and the structure destroyed. In chemical action we must also consider a double breathing action of the induced currents tending to expand each half wave by repulsion since the current on opposite sides of an electric whirl go in opposite directions.

Matter is necessary in all these actions for the same reason that it is needed in an electric wave to act as a core or guide to the wave. The wave, however, is an ether wave. Matter in some way marks the path of the current and allows a slip or motion of the ether.

It became apparent that in the light of our two basic facts, a heavy metal plate brought near an electric current and having its edge parallel with the current would stop the magnetic lines which encircle it symmetrically and reflect them by absorption to electric current, followed by formation of new magnetic lines,

the reflected beam. Since these light waves in this case are circles around the wire, *i. e.*, magnetic lines, we would expect them to curve back to the plate repeatedly until they finally curved over and around its far edge. But here appears an action that Newton describes above as characteristic of a wave,"A continual and very extravagant bending and spreading every way into the quiescent medium where they are terminated by it." The waves become a compromise between an actual wave and a flow resembling the action of water poured on the same plate from the direction of the wire.

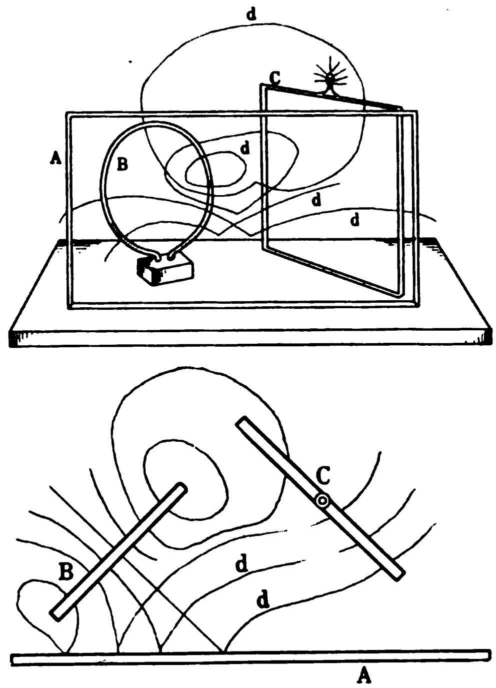

Fig. 2—Elevation and Plan of Reflection of Magnetic Lines(Curved Light) on a Plane in Free Space

A—Boundary of reflecting plane, a closed copper loop.
B—Radiating band oscillator.
C—Exploring band and lamp.
d, d, d,—Some of the curved lines generated by *B*, and reflected by the plane bounded by *A*. These lines are reflected through *C* and light the lamp.

We now see why a great radio wave being curved can encircle a mountain and return to its source, and why the earth being a poor conductor becomes semi-transparent and a poor reflector, and being irregular scatters the wave more than when it passes over water.

If there were holes in the above plate water would pour through, but these light rays cannot go through without violating the very law on which reflection is based, namely, that a line of force cannot pierce a closed circuit. The medium bends and sags as if the hole were a rubber sheet but cannot break. A single bounding closed circuit such as a heavy copper rectangle is as good as a solid plate. These waves act like the flow from a piston working back and forth in a cylinder open at both ends and immersed in water, while shorter visible light acts as if the piston were replaced with a diaphragm vibrating at tremendous speed, too fast for the inertia of the water.

This suggests that a tube would carry our long waves best and prevent them from curling into space and returning. If we try to make a line of force enter the end of a tube we encounter a closed circuit and the line is reflected. We must therefore make such a tube by bending the plate or closed loop spoken of above into the form of a tube with the edges overlapping but insulated. This presents no closed circuit until the wave tries to pierce the tube wall, when it is reflected. As expected there is more frequent reflection due to curved lines and also greater absorption resulting in low efficiency especially if the tube is thin.

A reflecting tube may be made by coiling a heavy sheet of copper around a cylinder making a tight spiral. It should be wound with a sheet of empire cloth to keep any two layers from touching. It should be ¾-in. thick. A laminated magnet may have one end inserted several inches into one end of the tube. The exciting coil should be placed close up to the tube to lessen leakage for we are increasing the reluctance and greater magnetomotive force is required. It is magnetomotive force that drives a light wave through space, and the reluctance or resistance of free space for this wave is over 1000 times that of iron.

The great amperage that such a tube must carry to reflect a 60-cycle wave makes it difficult to construct a tube that will not be disappointing except for plotting this region on various curves. To cast the tube and slot it is also troublesome. Vastly better results may be obtained with the 10-in. tubes described below using shorter waves and requiring very little metal in the tube walls.

Let us now digress by leaving this experiment for a little while, for we are working in the dark with this wave both literally and metaphorically, and we must have a means of easily exploring our magnetic field.

When we reflect the lines of force from a transformer core by an annular mirror we can explore the field outside by a coil and milliammeter. We can visualize our field better by using a coil of 250 or 500 turns of No. 10 wire carrying a 1½-volt flashlight lamp. We can bring this coil within about a foot without burning out the lamp and its varying brilliancy in different locations makes an excellent exploring system.

The writer has for years used a grounded heavy copper sheath between primary and secondary coils for protection on transformers of 60,000 to 125 volts for patrol stations and for insulating transformers used on high-tension telephone lines. This sheath has its edges overlapping and insulated to prevent a closed circuit. The delicate voice impulses pass readily through the metal at right angles with little loss. The power is now in the electrostatic lines, to which all substances may be transparent unless the edges trun back and touch, making the electrostatic line a radius of such a circuit. The writer considers

the electromagnetic wave as formed progressively from the electrostatic wave so that the magnetic line forms mostly outside of this sheath. The writer has arranged to show the development of the electric wave and light wave from a stationary static charge and demonstrate their relation in time and in the three dimensions of space. It may be sufficient in this abstract to say that a light wave of 60 cycles is made up like all others of two components at right angles, the electromagnetic and electrostatic fields. The two as shown by Maxwell's equations are equal, and the unit of the former divided by the unit of the latter is in the nature of a velocity which Maxwell showed to be the speed of light. These two forces and the electric current producing them, or induced by them, have their directions of propagations all at right angles to each other, *i. e.* they represent the three dimensions of space though all three tend to spread out into the other two dimensions. No two can bear a steady relation to each other in time, *i. e.* no two can be steadily coexistent in a cyclic current, but rise and fall at different times.

The light wave does not spring from the conducting wire. No current produces a magnetic line directly. It forms from the electrostatic line after it leaves the wire; an electrostatic line readily passes through a heavy metal plate with only the loss of the electromagnetic field developed in that short distance. An electromagnetic line cannot so pierce a plate; in other words a light wave may slip sidewise through a plate but not head on. We may place a string as the center of a light wave, or better an elastic band, and let it carry a disk with a torsional motion from side to side. The energy is then alternately kinetic and potential. The radius of the disk is the electrostatic line; the elastic band is the magnetic line and direction of propagation of the wave. The rim of the disk tends to be the electric current whenever it meets a conductor. The right and left rotations of the disk give an alternating current.

It is evident that the magnetic line or elastic band and the electric current or rim of the disk do not touch, or originate directly from each other.

It is hard to see how Newton and recently Einstein can be correct in stating that light is corpuscular, as it would spring from the wire radially like the electrostatic lines. The above illustration is very incomplete. The elastic band merely represents a direction. We would have to consider changes in all three forces and think of our disk as a smoke ring expanding and contracting and continually turning inside out but always touching the circumference of the wire. The illustration is given however to better understand the following experiment, which is beautiful to say the least.

A coil carrying a 1½-volt flashlight lamp is moved back and forth along and over the outside of the copper reflecting tube. It lights up and its varying brilliancy is a measure of the absorption of the beam traveling inside. Our disks readily come through the tube and induce a current in the coil, but when our elastic band bends and touches the tube it cannot go through. The disks are the only part that can induce a current. When they cut the tube at right angles they lie in the plane of an electric circuit, but it is not quite closed for the tube is slit down its length, so the tube wall is transparent. Now let the elastic band or magnetic line try to get out through the tube wall. As soon as it bends, the plane of the disks will change, for they are always at right angles to the band. If the band tries to pierce the side of the tube the disks must cross in the plane of the tube wall and the rim will lie wholly in metal, forming a complete circuit. This induces a current which throws out a new magnetic line, the reflected beam. Our exploring coil and lamp are only a mirror of high resistance with correspondingly low efficiency. A heavy short-circuited coil in its place stops the beam and reflects it on itself for the same reason that the beam cannot pierce the tube.

The efficiency of reflection at 60 cycles is of course very poor, but much better than expected. The mirror of course heats up. A short-circuited coil of wire makes a good reflector, but being a short circuit, does not allow of more than a minute's work at a time. A plate of aluminum needs to be about ¼ in. thick at least, and the thickness for other metals is inversely proportional to their conductivity. Thinner plates are more or less transparent. The necessary thickness also depends on the density of the lines of force of the light wave.

The writer therefore changed the design to produce a short efficient wave that would not enter deeply into the mirror. The apparatus consists of a small condenser and short spark gap in series with a 10-in. copper band of flat No. 6 wire, the condenser is supplied with 20,000 volts. The exploring loop is also a 10-in. or 12-in. band carrying a 1½-volt lamp. The mirrors are 10-in. or 12-in. complete bands soldered at the joint. The reflecting tubes are a little smaller and from 4 ft. to 10 ft long. as desired. The radiating band is better taped with one turn of empire cloth, and the end of the reflecting tube is brought near or is fitted inside the band.

The first tube was made by soldering No. 6 flat wire to form a network of 10-in. by 10-in. mesh. The edges were insulated and taped together. The tube was 8 ft. long. A taped band carrying a lamp was fitted tightly on the end of the tube. The lamp burned out, though one on a 12-in. band would not even light. The lines outside bent sharply back under the band and neutralized those inside the tube, the result on the lamp being zero. The 12-in. band was then moved over the tube toward the radiator and concentric with it. The lamp

was now gradually lighted showing a rather steep gradient of the lines to meet the curved lines on the other side of the radiating band.

Another tube was added at the end of the first and a collar with overlapping insulated edges was used to join them. Here we meet with a great surprise. Only when the collar is made of very flexible screen or foil tightly fitted over very thin insulation can any considerable radiation be forced into the second tube. The lines leak out through the thickness of paper. The whole operation reminds the observer very strongly of trying to mend a leaky joint of water pipe under heavy pressure. The writer considers the condition completely analogous.

Joints may be made tight by soldering wires across the joint such as to make it impossible to leak without piercing closed loops. Two wires or bands at the edges are sufficient if insulated and taped close together.

A 5-in. exploring band and lamp inside the tube shows that the field is intense at the intersections of the wires for reasons that are plain if the direction of induced currents is traced out. In passing the 10-in openings the lines sag outside due to their pressure or repulsion until the lamp fails to light.

The presence of a reflecting tube does not produce the effect expected on the assumption that lines tend to contract like an elastic band under strain. The lines on the other side of the radiating band do not change materially when the reflecting tube is introduced an inch away.

Cones similarly made were substituted for the tubes with great success and the lines were concentrated through a small aperture. A trough or half tube was used. It conducted the lines two or three times the normal distance before they escaped over the sides.

It may be argued that some other action, other than reflection, may give these results. To test this the radiating band was set in the center of a table and a square 12-in. by 12-in. receiving band with lamp was placed at right angles to it several inches away so that one of its vertical sides lay in the plane of the radiator. The two were placed far enough apart to prevent the lamp from lighting due to the curved lines passing through its loop. A rectangular closed band of No. 6 wire 12-in by 18-in. was used as a mirror and placed as the hypothenuse of the right angle. This made it at an angle of 45 deg. to the radiator. The lines of force are reflected through the lamp loop and the lamp may easily be burned out.

This experiment again shows four facts without the shadow of a doubt. The direction of propagation of a magnetic line and of light are identical, in other words a magnetic line with its attendant electrostatic field is an ordinary light wave with the magnetic line head on. The angle of incidence and reflection are equal. Reflection requires the conversion of the incident beam to electric current and the conversion of this current back to the reflected light beam. Therefore light travels in circuits tending to close and is not straight.

We have all considered light waves as radiating directly from an oscillator, the magnetic lines forming a series of bands directly across its path. Now we must consider light waves as circles around our wire. The extent to which these giant waves hold their shape can be easily worked out and should be studied. Apparently they lose their symmetry and degenerate more into a flow along the shortest return path, easily going around conducting objects by reflection and easily eddying around behind objects into the unstrained medium.

The analogy between long sound waves and long light waves in this respect is complete, for both cast indistinct shadows.

In a mixed sound beam of high and low pitch the base notes can be heard behind a building when the high notes cannot. The writer considers the medium to be much the same for light as for sound, a divisible material under pressure.

Mirrors may be made of loops, screen, sheet metal, or looking-glass. The surfaces need not be regular or polished. Wet boards, or other objects are also partially opaque and so will reflect very slightly, their action being best of course in the presence of dissolved salts, acids, or alkalis, and when acting on the longest waves.

Shadows are particularly interesting for they cannot be made distinct. The wave will curl through everything but a closed electric circuit. A 6-in. copper plate may be set in front of the radiator as an opaque screen and a lamp on a 5-in. loop can be lighted 3 in. behind its center. Solid plates should be used for screens. A loop allows the other to sag, so far that a concentric smaller loop lights up, close behind it. The electrostatic field must go to the loop to induce a current, and back before reflection can take place. If the loop is too large the first wave will pass before it can act; this is selective transparency, a part only of each wave passing through. By plotting the sag behind a loop we can measure the lateral speed of electrostatic lines. If they are longitudinal thrusts they will travel faster than light.

The action of these waves much resembles the action of the electric current itself, especially when they conduct along an iron core. The inducing of an electric current merely means that a light wave slips sidewise along a wire. It is the first half of the process of reflection. Similiarly if a light wave could slip sidewise in space it would create an electric potential. This is magnetic induction. The wire moves instead of the wave.

A light wave may not be a sine wave; a storage battery may be used to send an intermittent current into a coil of a laminated magnet and produce reflection that will light lamps like an alternating current.

In all experiments on 60 cycles the lamp may be

replaced by a coil and ammeter, or for remote regions, a telephone receiver. Shorter waves may be explored with a thermocouple, a detector, a wire resistance or hot wire ammeter, or a neon tube. The field can be very accurately plotted.

Experiments are being conducted on refraction through various insulating substances, liquid and solid. Refraction is least for long waves and lines would not cross at a focus but would turn back in curves so that refraction is difficult.

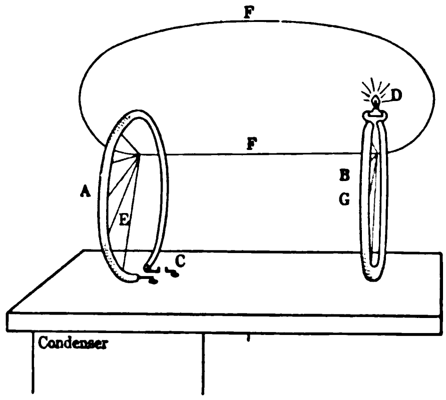

FIG. 3—ELECTROSTATIC LINES MAY PIERCE SOLID METAL

A—Heavy copper tube used as conduit enclosing insulated ring oscillator.
B—Heavy copper tube enclosing insulated exploring coil.
C—Spark gap.
D—1½-volt lamp.
E—Electrostatic lines coming from oscillator and generating electromagnetic line *F*.
G—Electrostatic lines generated by *F* which, after piercing tube *B* generate electric current in exploring coil. Part of *F* is reflected by lamp circuit.

Stationary waves in tubes are also being studied in an attempt to measure the speed of the waves along iron as compared with the same waves in space.

Of course it is understood that a stationary magnetic line from a direct-current magnet cannot be reflected except at the time it pierces a mirror, *i. e.*, while it is varying in intensity. It requires lateral motion of a magnetic line or matter in its neighborhood, to produce the electrostatic field.

The relation of these two fields is further shown by the high-voltage 10-in. band oscillator above described. Both this and its receiving band may be each encased in a heavy copper tube and the lamp still lights by induction through both tubes. See Fig. 3.

SPEED OF PROPAGATION

We have seen that light is retarded in free space and long waves seem to travel faster along iron.

We know that a static electric charge may travel at snail's pace or less along glass or sulphur and can have all speeds up to the speed of light.

These facts suggest experiment to see if the electrostatic field moving at right angles to the electromagnetic line or light ray travels at a higher speed, since it resembles a thrust or longitudinal wave. A loop reflector is interesting in this respect.

Referring to Fig. 4, let *A* represent a fixed band across which is stretched an elastic membrane. The arrow *C* in its flight will move past the ring until its energy is all taken up and becomes potential. It stops entirely for a moment, then moves backward gathering force until it is shot clear of the ring. This is reflection. When the arrow struck the membrane an impulse radiated along the membrane to the ring, and reaching the ring returned to react against the arrow and throw it back. The time intervals of the arrow in moving from the ring center *O* to *D* are nearly the same as the impulse takes to reach the ring *A* and return.

Our ring here represents an electric conductor in which a current is induced. The elastic membrane is the electrostatic field and the arrow is the electromagnetic or moving magnetic line of force or light ray. The only material substance here is the ring *A*.

The magnetic line *C* should travel the distance *O D* while the electrostatic field travels twice the distance *A O* or the diameter of the circle, or more properly a line between the distances *A O E* and *A D E*.

The speed of the arrow, if we neglect the loss of reflection (analogous to ohmic loss), is between its speed at *O* and at *D*, less than the speed of light.

The detail of experiments cannot be given here, but two annular split rings or wire boundaries were used as shields to get a pencil of rays in the center of a closed loop but protect the loop on both sides from actual contact with lines. The two shields were joined by a copper strip making a split cylinder. In this cage the sag of a closed loop was roughly measured with a smaller exploring coil brought up behind it until the lamp began to glow. This action corresponds to bringing the smaller ring and lamp just inside the strained membrane *A D E* in Fig. 4, so that the impulse of the membrane would strike it before it struck ring *A*.

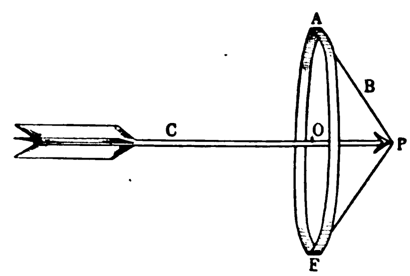

FIG. 4—SAGGING OF REFLECTING PLANES

From these preliminary trials as a forerunner of careful measurements it appears that the speed of the electrostatic lines is not materially different from the speed of light. The lighting of the lamp occurs with the distances *O D*: *A E* in the ratio of about 1 : 2, but better methods may show the two speeds to be identical.

The Absolute Zero

The absolute zero is—273 deg. cent. All heat has then been extracted from matter, and according to modern theory it would be quiescent throughout its mass. Charles' law shows that a gas contracts 1/273 of its 0 deg. cent. volume for every degree it is cooled, so that at absolute zero it would have contracted 273/273 of its volume and vanished. But under the kinetic theory of heat we have thought of molecules striking each other and passing the energy along, so we say that when a gas liquefies or solidifies, it nullifies Charles' law below that point.

The writer since his high school days has doubted this theory, but his only reason was the thought that solidification was only an accident as far as Charles' law is concerned.

More light was thrown on the subject when it was discovered that the electric resistance of the various metals decreases with lowering temperature at a rate that brings all currents to zero at approximately —273 deg. cent., *i. e.* 0 deg. K.

The interest in this discovery was enormously increased when Onnes at the Leiden Laboratory recently tested the electric resistance of a number of metals in liquid helium.

He found that mercury, tin and lead showed a decrease of 0.4 per cent per degree cent. from 0 deg. to a very low temperature. The decrease at a low temperature becomes less rapid until at a "critical temperature" which is 4.2 deg. K. for mercury, 3.8 deg. K. for tin, and 6 deg. K. for lead, the resistance suddenly drops to less than 2×10^{-11} times its 0 deg. cent. value, in range of 0.01 deg. cent. The metals are then called super-conducting. One thousand amperes per sq. mm. fail to sensibly heat small mercury wires and 600 amperes through lead wires give the same result.

At a certain critical current the wire regains its normal resistance. Unlike these metals, gold, platinum, and iron tend to approach a definite resistance down to the lowest temperature yet reached, 3 deg. K.

A current was induced in a coil of wire in liquid helium of 0.4 to 0.6 amperes, and persisted for four days decreasing about 1 per cent per hour. The remarkable lesson from these facts is that some elements near the absolute zero are subject to sudden changes in resistance, and there is a possibility of sudden changes at still lower temperature since various metals show this action at different degrees. A very considerable final change at the absolute zero such as is predicted by resistance curves with decreasing temperature, and by Charles' law is not improbable.

If temperature resistance curves have been correctly projected to a zero point at absolute zero and metals at that point no longer have ohmic resistance, it follows that all the electric current that man could generate could be carried without loss or heating, by a wire the size of a hair, in other words it means that if a wire once reaches absolute zero we could not again warm it by passing a current through it.

The above experiments bring out the startling fact that radiant heat would not warm it either, for at absolute zero the mirrors would have no electrical resistance and it follows that they would be perfect radiators without absorption or loss. If we focused the heat of the sun on them we could not warm them and they would reflect all energy they received.

Again if the writers theory of the conduction of heat be found correct, the conductivity of heat at very low temperature would be the same for various metals as for electric conductivity, and when the tiny electric whirls met no resistance at absolute zero, conductivity of heat would be perfect and none would be retained; all would simply work through and radiate into space. It follows then that matter once chilled to absolute zero cannot be revivified by even a white-hot object touching it.

How then can we again warm material so chilled? Perhaps by impact or friction of some sort. In any case such conclusions point to a total change of conditions at absolute zero and matter ceases to be matter as we understand it. Naturally it is almost impossible to extract the last few degrees of heat, but the total extraction of heat from a quantity of matter would be an achievement well worth tremendous effort. Some of the results near the absolute zero would be amazing. For instance if a small closed core transformer carrying a reflector ring, as its secondary, as illustrated in Fig. 1 were placed in liquid helium the primary would take enormous current and the ring reflector would become more and more efficient as the temperature was lowered, until at absolute zero all the magnetic lines would be reflected from the core into space and the entire energy of the primary coil would be reflected into space as curved light waves.

Let us now consider the latest research into the constitution of matter. The generally accepted theory of the atom is that it is made up of a positive electric charge as nucleus, which has negative electrons or electric charges revolving around or near it. These moving charges are equivalent to electric whirls or circuits.

Lorenz and other physicists consider the negative electrons as satellites in a plane, while some chemists like Dr. Langmuir think of them as revolving around fixed points of a symmetrical figure of three dimensions.

Two forces are in equilibrium and opposing each other. The negative electrons are kept from flying off by the attraction of the positive nucleus, and are kept from falling to that nucleus by some unknown force. The writer believes this force to be heat.

But whatever the form of the atom, if the above theory be considered it follows that when a line of force pierces such an electron orbit, it will be absorbed, then reflected, and the orbit will dilate, since the

charges on opposite sides of the orbit move in opposite directions and parallel currents or charges in opposite directions repel each other. On the other hand, when lines of force or rays of light or heat, which ever name we wish to give them, are gradually withdrawn, *i. e.*, when the substance is gradually cooled, we can think of the atom shrinking and the negative electrons slowly settling down closer and closer to the positive nucleus, perhaps in quantum steps, until at absolute zero the positive and negative parts are together and their static and magnetic fields are closed. They now become dead matter in the sense that a closed magnetized ring shows no magnetic field in the surrounding space, and in the sense that two condenser plates tight against each other send out practically no electrostatic lines into space. If a section be cut out of the ring magnet, or if one condenser plate be lifted at right angles to the other, like the wireless aerial, we at once have a positive and negative electromagnetic and electrostatic influence that makes itself felt throughout the universe.

It is of interest to note that the theory of negative electrons revolving around a positive nucleus is a theory of the constitution of the atom that is often accepted, and it has been suggested that a light ray is emitted when a negative electron moves from one orbit to another. This idea in effect suggests that the diameter of an atom is variable in irregular steps.

The writer's idea that the atoms close at absolute zero is his reason for believing that heat is the force which holds the electrons out from the positive nucleus, since all heat is extracted at absolute zero and a change of matter seems inevitable. Mass seems to be due only to electrostatic and electromagnetic forces, so the neutralizing of these would de-materialize matter and such de-materialized matter could not be detected by the senses or by any known instruments.

It must not be thought that all energy is extracted from such a de-materialized atom for heat is an insignificant portion of the energy of the atom.

The question is, can matter, so neutralized, be the ether of space and if so is the final change at absolute zero a falling away from the complex atom to a simple primary form, as simple as the hydrogen or helium atom, or simpler?

Structure of Space

Scientists are divided as to the structure of space; some believe in a medium, the so-called ether of space, others do not. Neither school has proved its claim, so both are equally entitled to their beliefs. The experiments above described seem to the writer to indicate a medium for the transmission of light consisting of small units or atoms under a pressure beyond our conception, that pressure being due to the average velocity of the ether particles, the ether being somewhat similar in its nature to a gas under pressure.

There may however be a system of mechanics with no analogy within our intelligence, and so perhaps incomprehensible to us.

The idea of an ether under pressure would mean that matter in many cases at least, was an obstruction to, not a container of energy and that the attraction of magnetic poles was due to the convergence of ether streams driving matter forward. This of course has no reference to the internal or inherent energy of matter. It may be objected that this would require an additional dimension or outlet. Whatever the objections raised against the theory, it certainly explains much more than the elastic solid theory.

There is a tremendous resistance in space to the passage of light at least to long waves, a thousand times more than along iron so that the passage of a wave through space may not be as simple as we imagine.

The idea of ether under pressure, makes quite logical the idea of actual flow at very low frequencies, changing to pulses or beats at higher frequencies where inertia comes into play, and finally, very minute waves of atomic size, like X-rays or gamma rays, may easily act on one unit or atom of ether and send it out like a projectile into space, "radiation traveling undissipated." It is then "corpuscular." Magnetic lines in the same direction repel only because they form an area of high pressure and try to relieve that pressure. Magnetic lines tend to contract only to equalize the pressure as the air in front of a fan forms similar pressure gradients or lines of force in filling in behind the fan, and in the same way that wind moves from an area of high pressure to one of low pressure. Since a small mirror will reflect its part of a giant wave it follows that there might easily be a scattering of an electric wave traveling along a wire in the possible local channels in its substance, or the current in a turbulent stream might be diverted into a multitude of eddies. This is ohmic loss. Conducted heat is a multitude of such electric currents emitting and reflecting repeatedly at all angles their characteristic or synchronous waves. These small systems and the main electric wave in our experiment differ only in size, just as our magnetic waves differ from visible light. This explains also selective radiation and absorption. Evidently these small circuits and the waves emitted resist the movement of the main current along a wire until they are eliminated at the absolute zero by some change in structure. On the other hand if the intensity of the electric current or any heat source is increased, some of the paths are broken up into smaller ones and the material becomes luminous. If the operation is increased to its limit probably all matter disintegrates to its primary substances. Heat determines the condition and physical attributes of matter. When heat is withdrawn matter ceases to have physical attributes.

If matter at absolute zero becomes a perfect conconductor of heat and electricity and if matter at absolute zero becomes the ether of space then space should conduct heat and electricity without loss. This is fulfilled in the transmission of radiant heat and in the

streams of electrons that cross from the sun to the earth without loss.

Each time we study matter and energy we find that our many chemical elements simplify to a less number, and our many forces also become fewer. Each time we hold the torch higher and peer further back, into the mystery we find creation coming closer to its origin. Our religion and our reason dictate that it was formed from nothing.

Dr. Einstein speaks of "space relations" as force. All matter is conceded to be stabilized energy. All our forces are merging into different aspects of the same one, but beyond this we have not been able to get any physical conception as to what energy is.

It is a known fact that an electrostatic charge or field in motion produces an electromagnetic line of force and a magnetic line of force moved ever so slightly produces electrostatic lines. These lines on the slightest motion produce an electric potential or current. The three forces represent the three dimensions of space. To that extent they are space relations whatever that means. Otherwise they are apparently compound and interlinked motions of a medium in space. Our modern experiments and theories of matter show it to contain nothing beyond these three forces. All the forces of nature deal with matter, so deal with only these three and it looks as if all forces contained only one or more of them. Cohesion and adhesion are not existent in matter. Tensile strength is the strength of interspace and it is the the interspace that finally breaks.

Again anyone of the three, plus motion, produces both the others. This looks as if they were aspects of the same thing and that the starting point of all creation is simple to an amazing degree. These facts are known but, so far, are little realized, for science has more than trebled her knowledge in the last few years and discoveries have come too fast to allow of realizing their meaning. The conservatism of the world also forbids.

Life is evidently intended to be the formation of indelible concepts of a solidity and reality that, from a scientific standpoint, are not what they seem. Our old theories should all be reviewed.

Ether may still be capable of being reopened as matter by radiation, or some other way. The writer expressed this thought before the Am. Chem. Soc. in 1918 and the Sigma Psi Society in 1919 at Seattle that the star dust of space was an evidence of continual recreation, and re-opening of the ether and the vast nebulae as of space were being continually produced. The foundation of worlds is then possible in new places from material transported without the interference of gravity. This work then becomes cyclic like everything else, only on a more magnificent scale in space and time.

Unfortunately it is difficult to find what if anything happens to the cold worlds of space or whether it is possible for parts of them to reach the absolute zero at any time and go to pieces.

That a nebula is only now drawing up into a world is difficult to reconcile with an infinite past, unless we consider it as recently brought to life and endowed with the force of gravity. The conception of such an ether particle is much like that of Dr. Langmuir's quantel arrived at from another angle.

If all space is filled uniformly, as Bergman's philosophy insists, then we can have a medium, each particle of which may be endowed with motion, the average of all being an unvarying pressure and capable of moving at high speed from an area of high pressure to an area of low pressure, producing by convergence the so-called attraction and repulsion of magnets and the attraction of gravity.

This theory would require that internal energy of a pound avoirdupois of matter after deducting its heat energy would exist in the quantity ether from which it came or to which it returns. The ether of space has been considered to posses mass and inertia. This thought is hard to reconcile but the various phenomena attributed to the ether show at least an equivalent property and therefore some resemblance to matter.

The latent internal energy in a pound of matter cannot be accurately computed and all we can find so far on the subject is the power liberated when radio active elements disintegrate. Radium teaches us most on account of its rapid disintegration. Rutherford estimates a liberation of from 2×10^9 to 5×10^{10} gram-calories from one gram of radium in degenerating to helium and probably to lead. This amounts to from 1,050,000 to 26,350,000 kilowatt-hours per pound avoirdupois. But beside this energy so liberated we still have the disintegration products helium and lead which are also supposed to have further enormous internal energy, for like radium they too are made up of positive end negative electric charges. Since they are not strongly radio active we have no way so far to compute their energy. The loss of weight of radium cannot so far be measured, as available amounts are too small, and the time since the discovery of the metal is too short for any reliable measurement. We cannot even guess if the change of atomic weight is any measure of the energy liberated or if the lead and helium weigh less than the radium from which they degenerate.

On the other hand if a pound avoirdupois of matter were to be accelerated to the speed of light, 186,000 miles per second, it would contain, due to this velocity 564,083,427 kilowatt-hours or 21.4 times the higher figure given by Rutherford as the amount of energy liberated from a pound of radium in changing to helium and lead.

It is evident that if matter vanishes at absolute zero it still holds a vast energy as the ether of space. This energy might be partly in velocity and partly in a form equivalent to mass.

Summary

The writer shows experimentally the following facts:

1. Reflection is not a simple operation. The re-

flected beam is not a continuation of the incident beam, there being an intermediate transformation of energy, light to electric current, and electric current to light.

2. Light, with the exception of very short rays, does not travel in straight lines but travels in closed circuits tending to come back to the starting point.

3. A moving magnetic line of force and light ray are identical and their direction of propagation is the same.

4. Very long light waves obey Oersted's law instead of the law of inverse squares. The shorter the wave, the further it leaves Oersted's law, and the closer it obeys the law of inverse squares, up to the wave lengths somewhat beyond ultra violet; after that, light seems to be corpuscular the rays being so short that they act on single ether particles.

5. The phenomenon of repulsion of light is identical with the repulsion of unlike magnetic poles, and is a difference of phase relation between the light wave and the electric current it induces. It is identical with the repulsion between the primary and secondary currents of a transformer.

6. The kinetic theory of heat is untenable. The so-called Brownean movements of suspended particles prove intense vibration in the particles of matter, but that vibration is the effect, not the cause of heat. It is the effect of the repulsion of light, the repulsion due to phase difference. Conduction of heat is repeated reflection of radiant energy.

7. An electric current is not the direct source of a magnetic line. The electrostatic and electromagnetic fields of a changing electric current are produced progressively, not simultaneously, the electrostatic field being first produced and the electromagnetic field being in turn produced from it.

8. Conversely a magnetic line does not generate an electric current except through the medium of the electrostatic field at right angles to it.

9. Very long light waves may be generated at a point and conducted along magnetic substances as a core or guide, just as an electric current travels along a wire, except that the direction of propagation of an electric current and light wave differ in space by 90 deg. These waves may also be conducted by reflection.

10. Except in cases of selective absorption the efficiency of a reflector is the same as the electric conductivity of the material from which it is made, *i. e.*, the loss in reflecting a beam of light is ohmic loss in the reflector.

From these facts and the facts and theories of eminent scientists the writer deduces the following assumptions:

1. Light meets tremendous opposition in free space. In the case of long light waves this is over 1000 times greater than in iron.

2. Long light waves in iron travel faster than the so-called speed of light.

3. The electrostatic or lateral field of a light wave may be more of a longitudinal impulse, and may be found to travel faster than a light wave in its direction at 90 deg. to the wave.

4. Very long light waves are of the order of displacement currents. As the frequency rises, waves become more and more a vibration rather than a current. X-rays are copuscular.

5. There is an ether of space, a divisible material under enormous pressure, not an elastic solid as generally supposed, though it is highly elastic.

6. Matter disappears at the absolute zero. Charles' law holds at all low temperatures. Heat is the force that holds the negative electrons of an atom away from the positive nucleus. When heat is entirely withdrawn the opposite charges are together, and the electromagnetic and electrostatic fields are closed or nearly closed. These fields give matter its properties.

At the absolute zero matter cannot be again warmed by electric resistance, by conduction of heat or by concentration of heat rays. The complex atoms have dissociated to the simpler or primary form, not amenable to the laws of matter and the electrostatic and electromagnetic fields are closed or nearly so.

7. Matter when it reaches the absolute zero, *i. e.*, when all heat is withdrawn becomes the ether of space. Matter is a special form of the ether.

8. Gravity is a function of the electromagnetic and electrostatic forces and so disappears at the absolute zero when these fields close or become exceedingly small.

9. Matter is being continually formed by the opening up of the fields of the ether particle, thereby forming the atoms of matter. The continual formation of matter is shown in the formation of star dust and nebulae which often consist of the simplest elements.

10. The energy of heat is insignificant compared with the internal energy of matter. The enormous internal energy of matter as exhibited in radio active elements then becomes the energy of the ether and may occupy still less space. Mass changes largely to velocity of the ether particle, this velocity being a function of the speed of light. There is still left something akin to mass and inertia.

11. Matter and the ether can act on or "grip" each other only at high relative velocity. This presupposes ordinary magnetic lines to be moving streams at high velocity.

Ether will not slow up a comet though it consists of the thinnest and finest dust, but moves a conducting wire or a magnet with tremendous force.

12. All matter and energy finally resolve into three forms representing the three dimensions of space, namely electric current, the electrostatic field and the electromagnetic field.

The full paper and detail of apparatus and these and subsequent experiments will shortly appear in book form.

Abstractive and Selective Properties of Radio Antenna Circuits

BY EDWARD BENNETT

Professor of Electrical Engineering, University of Wisconsin

1. *Introductory*: This paper is an analytical study of the power abstractive and selective properties of simple series radio antenna circuits.[1] It does not deal with the properties of coupled circuits, or of amplifying circuits, or of differentially connected circuits which utilize a difference in the direction of propagation of the waves from the correspondent station and the interferent sources to reduce interference. A discussion of the selective properties of the simple series circuit is a necessary, or at least a very helpful, preliminary to the treatment of coupled, amplifying and differentially connected circuits.

The present paper is a continuation of the studies appearing in two former papers: the first paper[2] showing that the radiating and ultimate abstracting powers of a high power extended horizontal network are both independent (within limits) of the mounting heights of the network, and the second paper[3] dealing with the computation of the wasteful resistances of extended antennas. The present paper is devoted to a consideration of the properties of the simple series antenna circuit, with the object of determining the circuit proportions and frequencies which will make the circuit most highly responsive to the correspondent's signal and unresponsive to interferent sources.

2. *Basis of comparison of receiving circuits. Method of treating the detector.* The second paper referred to above concludes as follows: "The relative merit of high and low antennas is determined not alone by the radiating and absorbing efficiencies of the two types but also by considerations having to do with the power generating devices and the selective reception of signals under the conditions of commercial operation. For example: the function of a receiving antenna is not simply to deliver to a detecting device energy abstracted from impinging waves. Its function is to *selectively* abstract energy from the impinging waves and to deliver it to the detecting device. The ultimate comparison of the relative merits of the two antennas for receiving purposes under the conditions to be met in commercial operation must be a comparison of the amounts of energy delivered to the detectors from the desired correspondent when the strengths of the interfering signals or noises have been reduced to the same intensity in the two cases."

We now propose to make a comparison of the relative amounts of energy delivered by a sustained wave correspondent station and by different interferent sources to resistor detectors associated with antennas of various forms when operated at various frequencies. To permit of a general mathematical treatment of the circuits, it is assumed that any detector, no matter how it may draw energy from the oscillating circuit, (whether as an ordinary resistance, as in the Fessenden hot wire barretter; or at a more than proportionally greater rate at the peak of the voltage, as in the audion; or intermittently, as in the Poulsen ticker) may, *in its effect upon the oscillation of the circuit,* be replaced by a resistance connected in series in the circuit. Such an equivalent resistance will be referred to as a *resistor detector*. The resistance assigned to such a detector must be such that the average power expenditure in the resistor is equal to the average power expenditure in the actual detector.

It is further assumed that the power from the correspondent station delivered by a circuit to such a resistor detector, or the energy delivered to the detector in a given interval, is the measure of the merit of the circuit. In other words, the thing necessary to the operation of any detector is the supply of energy to it at a definite rate. If a circuit, or combination of circuits, will supply the necessary energy—after sifting out the energy from the interferent sources—it is always possible by means of a transformer to adapt this energy to the voltage current requirements of any detector.

3. It may be well at this point to note the methods of associating a detector with a circuit and the conditions to be fulfilled under each method in order to make the delivery of power to the detector a maximum. The circuit with which the detector is to be associated may be either the antenna circuit itself, or a secondary or a tertiary circuit. Fig. 1, 2, and 3 illustrates the simplest case, the case in which the detector is associated directly with the antenna. The statement of the conditions to be fulfilled applies only to the reception of undamped waves and for the case in which the time constant of the receiving antenna does not exceed 0.2 of the Morse dot interval.

When receiving undamped waves with a given antenna the power expenditure in a series resistor detector (Fig. 1) is a maximum if the resistance of the detector is made equal to the antenna resistance R_a. (The

1. This study was carried out with the support of the International Radio Telegraph Co. I have embodied in the paper constructive suggestions contributed by H. M. Crothers and L. J. Peters of the University of Wisconsin.

2. "High Versus Low Antennas in Radio Telegraphy and Telephony" by Edward Bennett, *Bulletin* of the University of Wisconsin, number 810, Engineering Series, Vol. 8, Sept. 1916.

3. "Feasibility of the Low Antenna in Radio Telegraphy," by Edward Bennett, *Proc. Inst. Radio Eng.*, Vol. 6, October 1918.

antenna resistance R_a is the sum of the radiation resistance R_r plus the wasteful resistance R_w.) Under these conditions the power expenditure in the detector is $E^2/4\,R_a$ in which E represents the r. m. s. value of the voltage induced in the antenna by the impinging waves.

If the resistor detector, instead of being connected

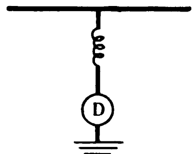

FIG. 1
R_d should equal $(R_w + R_r)$

in series in the circuit, is connected in shunt to the antenna inductance as in Fig. 2 the detector resistance should have the following value in order to lead to the same power absorption.

$$R_d \text{ should equal } \frac{R_c^2}{4\,R_a}$$

in which R_c is the critical resistance $2\sqrt{\frac{L}{C}}$ of the circuit.

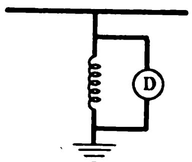

FIG. 2
R_d should equal $\frac{R_c^2}{4\,(R_w + R_r)}$

If the resistance of a given type of detector is (n) times the antenna resistance, it can be connected as in Fig. 3 in the secondary of a transformer. With the transformer connection, the following relations

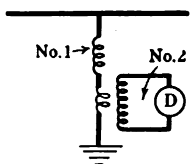

FIG. 3
X_2/X_1 should equal R_2/R_1
X_m " " $\sqrt{X_1 X_2 + R_1 R_2}$

should be satisfied if the power expenditure above noted is to be obtained in the detector.

$$\frac{X_2}{X_1} \text{ should equal } \frac{R_2}{R_1}$$

$$X_m \quad \text{"} \quad \text{"} \quad \sqrt{X_1 X_2 + R_1 R_2}$$

R_2 is the resistance of the secondary, mainly the detector resistance.

R_1 is the antenna resistance R_a

X_2 and X_1 are the net reactances of the secondary and primary circuits. If X_1 is inductive, X_2 must be inductive, if X_1 is condensive X_2 must be made condensive.

X_m is the mutual reactance between primary and secondary circuits.

4. *Classification of correspondent and interferent combinations.* The following is a classification of the correspondent and interferent combinations which are encountered in the operation of radio stations.

TABLE I

CORRESPONDENT AND INTERFERENT COMBINATIONS

I. Correspondent—a sustained wave station.
  1. Interferent—a sustained wave station.
    A. Slightly detuned, say by 1 per cent.
    B. Greatly detuned, say by an octave.
  2. Interferent—a spark station
    A. Of the same frequency
    B. Slightly detuned, 1 per cent
    C. Greatly detuned, an octave.
  3. Interferent—a suddenly applied and long sustained induced voltage, or the sudden release of a bound charge.
  4. Interferent—an induced voltage impulse.

II. Correspondent—a spark station.
  1. Interferent—a sustained wave station.
    A. Tuned to the same frequency.
    B. Slightly detuned, 1 per cent.
    C. Greatly detuned, an octave.
  2. Interferent—a spark station.
    A. Slightly detuned, 1 per cent.
    B. Greatly detuned, an octave.
  3. Interferent—a suddenly applied and long sustained induced voltage, or the sudden release of a bound charge.
  4. Interferent—an induced voltage impulse.

The subsequent discussion will be limited to the case in which the correspondent station is a sustained wave station.

5. *Relative response of simple series antenna circuits to undamped detuned waves; three numerical illustrations.* As a preliminary numerical illustration of the subsequent discussion, let us consider three antenna circuits with the detector represented as an ohmic resistance directly in series in the antenna, as in Fig. 1.

Antenna H is the Darien Naval Station antenna having a height of 146 meters.

Antenna L is an antenna having an extended network 10 meters high and of such an area that it radiates at the same rate as the Darien antenna when operated at the same voltage and frequency. It may be called the 10-meter Darien-equivalent antenna.

Antenna S has an extended network 10 meters high but of 1/20 the area of the 10-meter Darien-equivalent network.

Assume that these three antennas are all made resonant to the same frequency, and are used to receive undamped waves of the same intensity. Let the ratio of the wasteful resistance R_w of the antenna plus its radiation resistance R_r to the radiation resistance

be represented by k. Assume that the detector resistance R_d is made equal to the sum of the wasteful resistance plus the radiation resistance, or is made equal to $k R_r$, thus making the total resistance R_t equal to $2 k R_r$.

$$k \text{ represents } \frac{R_w + R_r}{R_r} \tag{1}$$

$$\left.\begin{array}{l} R_d \text{ assumed equal to } R_w + R_r = k R_r \\ \text{then } R_t = R_w + R_r + R_d = 2 k R_r \end{array}\right\} \tag{2}$$

If the height of the high antenna is (n) times as great as that of the low antenna, and if the area of the large network is (s) times as great as the area of the small, then the constants of the three antennas to the resonant frequency are related in the manner shown in Table II.

TABLE II
RELATIVE CONSTANTS OF HIGH, LOW, AND SMALL ANTENNAS TO THE RESONANT FREQUENCY

Antenna	H	L	S
Height of antenna	$n h_0$	h_0	h_0
Area of antenna	$S a_0$	$S a_0$	a_0
Induced voltage	E_0	E_0 / n	E_0 / n
Capacity	C_0	$n C_0$	$n C_0 / s$
Inductance	L_0	L_0 / n	$s L_0 / n$
Radiation resistance	R_0	R_0 / n^2	R_0 / n^2
Final current	$\frac{E_0}{2 k R_0}$	$\frac{n E_0}{2 k R_0}$	$\frac{n E_0}{2 k R_0}$
Final condenser voltage	$\frac{E_0}{2 k R_0 C \omega}$	$\frac{E_0}{2 k R_0 C \omega}$	$\frac{s E_0}{2 k R_0 C \omega}$
Final stored energy $1/2 L I^2$	$\frac{L_0 E_0^2}{8 k^2 R_0^2}$	$\frac{n L_0 E_0^2}{8 k^2 R_0^2}$	$\frac{s n L_0 E_0^2}{8 k^2 R_0^2}$
Final power to detector ($I^2 R_d$)	$\frac{E_0^2}{4 k R_0}$	$\frac{E_0^2}{4 k R_0}$	$\frac{E_0^2}{4 k R_0}$
Time constant (seconds)	$\frac{L_0}{k R_0}$	$\frac{n L_0}{k R_0}$	$\frac{s n L_0}{k R_0}$

R_d assumed equal to $R_w + R_r = k R_r$

The numerical values of the constants of these three antennas are given in Table III for the following frequencies:

1. A frequency equal to the resonant frequency of the antenna. The resonant frequency is taken as 120,000 cycles per second, corresponding to a wave length of 2500 meters.
2. A frequency 1 per cent higher or lower than the resonant frequency; such a frequency cannot always be advantageously eliminated by heterodyne methods.
3. A frequency which is an octave higher or lower than the resonant frequency. Interferent waves of such a frequency would only be troublesome if from a near-by station.

This table also contains data similar to the above for the case in which the antennas are tuned to be resonant to 30,000 cycles, corresponding to a wave length of 10,000 meters. The table shows also the relative *steady-state* power expenditures in the detectors which result from impinging waves of the same intensity and of the above frequencies. In the lines showing the power expenditure, P_0 and P_1 represent the steady-state power expenditure caused by impinging waves of the resonant frequency in the Darien antenna for the hypothetical case in which the wasteful resistance R_w is negligibly small in comparison with the radiation resistance R_r.

6. *The selective coefficient of a receiving circuit.* Let the steady-state *selective coefficient* S_c of a receiving circuit *against* a specified detuned frequency be defined to mean the ratio between the power delivered to the detector by waves of a frequency such as to make the circuit resonant and the power delivered to the same detector by waves *of the same intensity* but of the specified detuned frequency; the power being determined after the current builds up to the steady-state value. A high selective coefficient against detuned frequencies is highly desirable in radio receiving circuits.

The numerical values of the selective coefficients of the high, low and small antennas to the detuned frequencies specified in Table III are the appropriate ratios of the numbers appearing in the lines entitled "Power expended in the detector." From this table it will be seen that the high selective coefficients are to be obtained by using receiving antennas of small area and low height at low frequencies. It should be noted, however, that to obtain this continued increase of the selective coefficient with the decrease in the dimensions of the antenna and in the operating frequency, the wasteful resistances of the antennas must be kept proportional to the radiation resistance; that is, the wasteful resistances must be made smaller and smaller as the antenna dimensions and the operating frequency are decreased.

7. *Relations between the selective coefficient and the antenna dimensions and operating frequency.* The relations between the value of selective coefficient and antenna dimensions and operating frequency may be readily deduced by tabulating the antenna constants in the sequence shown in Table IV. The relations brought out in Table IV may be summarized thus.

The selective coefficient of a highly *oscillatory* antenna against a frequency which is detuned by a small decimal part (p_d) of the resonant frequency f_r varies:

a. inversely as the square of the antenna height.

b. inversely as the square of the area of the antenna network.

c. inversely as the sixth power of the resonant frequency

d. directly as the square of the decimal part (p_d) by which the interferent frequency is detuned.

e. directly as the square of the utilization efficiency ($1/k$) of the antenna.

$$S_c \text{ varies as } \frac{P_d^2}{a^2\, h^2\, k^2\, f_r^6}$$

This expression may also be derived by the following arguments. In any *highly oscillatory* circuit, the impedance Z to an electromotive force which is detuned by a small decimal part p_d of the resonant frequency, is substantially equal to the net reactance to the dissonant frequency or

On the other hand, the power expended by the resonant electromotive force E in the detector of resistance $k\, R_r$ connected in an antenna having an additional antenna resistance of $k\, R_r$, is,—

$$P_2 = \frac{E^2}{4\, k\, R_r}$$

Therefore the selective coefficient S_c of any highly oscillatory circuit is,

TABLE III

CONSTANTS OF HIGH, LOW, AND SMALL ANTENNAS

	Darien antenna	10-meter Darien equivalent	10-meter 5 per cent area	Darien antenna	10-meter Darien equivalent	10-meter 5 per cent area

Power expended in detector	0.98 P_0/k*	0.23 P_0/k*	0.00019 k P_0	0.0034 k P_1*	1.9 × 10^{-5} k P_1	4.7 10^{-5} k P_1
Constants to a frequency an octave high or low						
Net reactance ohms	198.	13.6	273.	797.	54.2	1090.
Total resistance "	10.7 k	0.05 k	0.05 k	0 67 k	0.0032 k	0.0032 k
Impedance "	198.	13 6	273	797.	54.2	1090.
Power expended in detector	2.9 × 10^{-1} k P_0	1.35 10^{-5} k P_0	3.4 10^{-8} k P_0	7.0 10^{-7} k P_1	3.5 10^{-4} k P_1	8.2 10^{-12} k P_1

P_0 and P_1 represent the power expended in the detector when R_w is zero.

*These figures are correct only for the case in which $k = 2$

$R_d = R_w + R_r = k\, R_r$.

$$Z\ (= X_L - X_c) = 2\, p_d\, X$$

in which, X is the reactance of the circuit inductance (or of the condenser) to the resonant frequency f_r.

Therefore the current I which results from the dissonant electromotive force E is

$$I = \frac{E}{2\, p_d\, X}$$

and the power expended in the detector of resistance $k\, R_r$ by the dissonant electromotive force is

$$P_1 = \frac{E^2\, k\, R_r}{4\, p_d^2\, X^2}$$

$$S_c \left(= \frac{P_2}{P_1} \right) = \left(\frac{p_d\, X}{k\, R_r} \right)^2 \qquad (3)$$

Since the critical resistance R_c of a highly oscillatory circuit is equal to twice the reactance of its inductance (or of its condenser) to the resonant frequency, equation (3) for the selective coefficient may be written in the following form:

$$S_c = \left(\frac{p_d\, R_c}{2\, k\, R_r} \right)^2 \qquad (4)$$

Now the radiation resistance and capacity reactance

of an extended antenna network are given approximately by the following expressions:

$$R_r = \frac{160\,\pi^2 f^2 h^2}{s^2}$$

$$X = \frac{1}{2\,\pi f C} = \frac{1}{2\,\pi f}\ \frac{h}{p_0\,A}$$

in which,

h represents the height of the network in cm.

a represents the area of the network in sq. cm.

p_0 represents the permittivity of air, $= 8.84\ 10^{-14}$

s represents the velocity of light, $= 3.10^{10}$ cm. per sec.

Therefore the equation for the selective coefficient (equation 3) may be written,

$$S_c = \frac{p_d^2}{k^2}\left(\frac{h}{2\,\pi f\,p_0\,a}\right)^2\left(\frac{s^2}{160\,\pi^2 f^2 h^2}\right)^2$$

$$S_c = \frac{9\,p_d^2\,s^6}{64\,\pi^4\,k^2\,h^2\,a^2\,f_r^6} \qquad (5)$$

We proceed to examine the limits within which the equations for the *steady-state* selective coefficient of a circuit will represent the selective properties of the circuit when the electromotive force is impressed, not for an unlimited time, but for a Morse dot interval only.

8. *Relation between the selective coefficient and the time constant of a circuit.* The expression for the time constant T_c of a series antenna circuit may be written in the forms:

$$T_c = \frac{2\,L}{2\,k\,R_r}\ \text{seconds}$$

$$T_c = \frac{3\,s^3}{16\,\pi^3\,k\,a\,h\,f_r^4}\ \text{seconds} \qquad (6)$$

On comparing these expressions for the time constant with equations **3**, **4** and **5** for the selective coefficient, it is seen that the expressions for the steady-state selective coefficient may be written in the following forms:

$$S_c = (2\,\pi\,f_r\,p_d\,T_c)^2 \qquad (7)$$

$$S_c = (2\,\pi\,c_d\,T_c)^2 \qquad (7a)$$

in which

c_d represents the number of cycles per second by which the interferent source is detuned.

TABLE IV

EFFECT OF THE ANTENNA HEIGHT AND AREA AND THE RESONANT FREQUENCY UPON THE SELECTIVE COEFFICIENT OF HIGHLY OSCILLATORY RECEIVING ANTENNAS

The table is based upon the assumption that the net reactance of the circuit to the detuned frequency greatly exceeds the ohmic resistance of the circuit.

	Effect of height		Effect of area		Effect of resonant frequency	
Height	h	$n\,h$	h	h	h	h
Area	a	a	a	$s\,a$	a	a
Frequency	f	f	f	f	f	$b\,f$
Induced voltage	E	$n\,E$	E	E	E	E
Capacity or Inductive reactance	X	$n\,X$	X	X/s	X	X/b
Net reactance under p_d decimal parts detuning	$2\,p_d\,X$	$n\,2\,p_d\,X$	$2\,p_d\,X$	$2\,p_d\,X/s$	$2\,p_d\,X$	$2\,p_d\,X/b$
Total circuit resistance	$2\,k\,R$	$2\,k\,n^2\,R$	$2\,k\,R$	$2\,k\,R$	$2\,k\,R$	$2\,k\,b^2\,R$
Current at detuned frequency	$\frac{E}{2\,p_d\,X}$	$\frac{E}{2p_d\,X}$	$\frac{E}{2\,p_d\,X}$	$\frac{s\,E}{2\,p_d\,X}$	$\frac{E}{2\,p_d\,X}$	$\frac{b\,E}{2\,p_d\,X}$
Current at resonant frequency	$\frac{E}{2\,k\,R}$	$\frac{E}{2\,k\,n\,R}$	$\frac{E}{2\,k\,R}$	$\frac{E}{2\,k\,R}$	$\frac{E}{2\,k\,R}$	$\frac{E}{2\,k\,b^2\,R}$
Power to detector at detuned frequency	$\frac{E^2\,k\,R}{4\,p_d^2\,X^2}$	$\frac{E^2\,k\,n^2\,R}{4p_d^2\,X^2}$	$\frac{E^2\,k\,R}{4\,p_d^2\,X^2}$	$\frac{s^2\,E^2\,k\,R}{4\,p_d^2\,X^2}$	$\frac{E^2\,k\,R}{4\,p_d^2\,X^2}$	$\frac{E^2\,b^4\,k\,R}{4\,p_d^2\,X^2}$
Power to detector at resonant frequency	$\frac{E^2}{4\,k\,R}$	$\frac{E^2}{4\,k\,R}$	$\frac{E^2}{4\,k\,R}$	$\frac{E^2}{4\,k\,R}$	$\frac{E^2}{4\,k\,R}$	$\frac{E^2}{4\,k\,R}$
Power at resonant frequency / Power at detuned frequency	$\frac{p_d^2\,X^2}{k\,R_1^2}$	$\frac{n^2\,p_d^2\,X^2}{k^2\,R^2}$	$\frac{p_d^2\,X^2}{k^2\,R^2}$	$\frac{s^2\,p_d^2\,X^2}{k^2\,R^2}$	$\frac{p_d^2\,X^2}{k^2\,R^2}$	$\frac{b^4\,p_d^2\,X^2}{k^2\,R^2}$

NOTE: In each antenna the antenna resistance ($R_w + R_r$) is assumed to be equal to k times the radiation resistance R_r and the detector resistance is assumed equal to $k\,R_r$.

In other words, an extremely high selective coefficient is to be obtained only by using a long time constant. Now if the time constant of the circuit is made so long that in the interval T_e during which the voltage is impressed (the Morse dot interval in sustained wave reception, and the length of the wave train in spark systems), the current has time to build up to only a small fractional part of its steady-state value, then the energy which is delivered to the detector by the resonant voltage is only a small fractional part of the energy which would be delivered to the detector in an equal interval of time after the steady-state is attained. On the other hand, the initial rate (the rate during the first beat) at which energy is delivered to the detector by the detuned electromotive force is approximately equal to twice the rate at which energy is delivered to the detector by the steady-state detuned current. (See Fig. 5.)

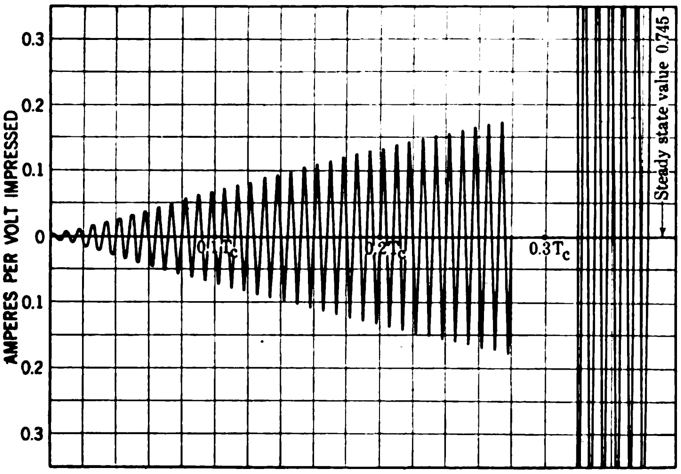

FIG. 4—RISE OF CURRENT IN DARIEN ANTENNA

Impressed frequency = resonant frequency
$R_t = 4\ R_r = 1.34$ ohms
R_c = 1060 ohms
$T_c = 0.0042$ sec. = 126 periods
$E/R = 0.745\ E$

As an illustration of this discussion, the curves showing the manner in which the current builds up in the ten meter Darien-equivalent antenna under resonant and under detuned electromotive forces have been plotted in Figs. 4 and 5. In Fig. 4 the circuit is resonant to the impressed frequency (30,000 cycles), and in Fig. 5 the impressed frequency is 8 per cent higher or lower than the resonant frequency. The circuit constants for these curves are to be found in column 7 of Table III.

Let the time interval during which the electromotive force is impressed in the (antenna) circuit be called the *time interval of excitation*, T_e. In sustained wave systems, the time interval of excitation is the Morse dot interval, (0.05 second at a speed of thirty words per minute). In spark systems, the interval of excitation may be said to be the effective length, (which we do not at present attempt to define) of the wave train. An inspection of Figs. 4 and 5 indicates that if the time constant of an antenna is longer than one tenth of the interval of excitation, the expressions for the selective coefficient (equations 3, 4, 5 and 6) which have been derived for the steady-state conditions fail to represent the relative amounts of energy delivered to the detector at the detuned and resonant frequencies.

We are now in a position to correct an erroneous conclusion to which equation (**5**) is likely to lead.

$$S_c = \frac{9\ p_d^2\ s^6}{64\ \pi^4\ k^2\ a^2\ h^2\ f_r^6} \tag{5}$$

This expression for the selective coefficient would indicate that to obtain a high selective coefficient the operating frequency should be low and the dimensions of the antenna small. While this conclusion would be correct for a radio transmission system operating with an uninterrupted flow of power, it is grossly erroneous for a make and break communication system. In a dot and dash communication system it is not permissible to decrease the dimensions and the frequency indefinitely; because with this decrease, the time constant of the circuit increases, and a condition may very readily be reached in which the time constant of the circuit far exceeds the Morse dot interval. Under this condition, the current at the resonant frequency has only time to build up to a small fractional part of the full or steady-state value, and equation (**5**) fails to express the *Morse-dot-interval-*selective-coefficient. Accordingly, the conclusions drawn from equation (**5**) should be discarded; the steady state selective coefficient should be expressed in terms of the resonant frequency and the time constant, as in equation (**7**), and the indications of this equation followed. This equation indicates that to obtain a high selective coefficient, the resonant frequency should be high and the time constant as long as possible, subject to the limitations which we proceed to develop in Sections 8, 9 and 16.

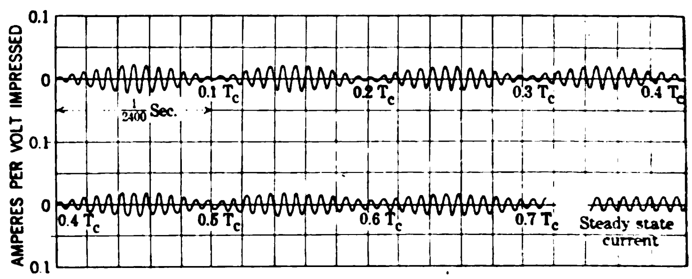

FIG. 5—RISE OF CURRENT IN DARIEN ANTENNA

Impressed frequency = $(1 + 0.08)$ resonant frequency
Resonant frequency = 30,000
$R_t = 4\ R_r = 1.34$ ohms
R_c = 1060 ohms
X = 84.6 ohms
Beats per sec. = 2400
$T_c = 0.0042$ sec. = 126 periods = 10 beats
$E/Z = 0.0118\ E$

9. *The Limit Placed on the Time Constant by the Necessity for Intervals of Silence.* The following consideration precludes the use, in a sustained wave system, of a receiving circuit whose time constant is much longer than 0.2 of the Morse *space interval.* The oscillating current in the receiving antenna circuit does not cease at the end of the Morse dot interval when the induced voltage ceases, but, because of the energy which has been stored, the current continues to flow with gradually diminishing amplitude. At the end of the space between the dots and dashes, the oscillatory current is not necessarily zero; but if the time constant of the receiving circuit is equal to the Morse space interval, the current is still equal to 36.8 per cent of its value at the end of the previous dot or dash. That is, if the time constant of the circuit is as long as the Morse space interval, the current in the receiving circuit would never cease but would fluctuate over a range of about 2.7 to 1. Under these conditions, the supply of power to the detector would fluctuate in the ratio of 7.3 to 1, and the note in the telephone would not be a series of dots and dashes but a continuous note of varying intensity. Let us assume that to provide for an interval of silence during the space between Morse dots and dashes, the time constant of the receiving circuit should be so short that the current in the receiving circuit will die down to one per cent of its initial value. This is equivalent to saying that the length of the Morse space interval should be 4.6 times as great as the time constant of the circuit, or that the time constant should not exceed 21.6 per cent of the Morse space interval. Since the Morse dot and Morse space intervals are equal, the time constant of the receiving circuit in sustained wave systems should not exceed 0.2 of the interval of excitation — the Morse dot interval. As the space or the dot interval at thirty words per minute is 0.05 second, the time constant of the receiving circuit should not exceed 0.01 second.

Since in a spark system it is not necessary to provide for intervals of silence (zero energy delivery) between sparks, but simply to make the time constant so short that the energy received from each wave train is delivered to the telephone receiver in distinct pulses, it is not necessary to reduce the time constant to 0.2 of the interval between periods of excitation. The time constant may be allowed to equal 40 per cent of the time interval between wave trains. In rapidly damped spark systems, the space interval between wave trains may equal 90 per cent or more of the interval between sparks. Under these conditions the time constant of the circuit should not exceed 0.4 of the interval between sparks, or at 1000 sparks per second should not exceed 0.0004 second. In such a rapidly damped spark system, *if* the effective length of the wave train is 0.1 of the interval between sparks, it follows that the time constant of the circuit may be four times as long as the interval of excitation.

10. *The Selective Coefficient for the Interval of Excitation.* Let the *selective coefficient* (of an antenna circuit) *for the interval of excitation,* T_e, against a specified detuned frequency be defined to signify the ratio between the energy delivered to the detector by an impressed alternating electromotive force of a frequency such as to make the circuit resonant and the energy delivered to the same detector by an impressed electromotive force of the same value but of the detuned frequency, both electromotive forces being impressed for the same interval of time, T_e.

Perhaps the most satisfactory method of determining the conditions under which, and the extent to which, the selective coefficient as above defined differs from the steady-state selective coefficient, is to plot the curves which will show the effect of the length of the circuit time constant upon the ratio between the energy delivered to the circuits by an electromotive force impressed for an interval T_e and the energy which would be expended in the circuits in the interval of time T_e by the steady-state current corresponding to the impressed electromotive force. Ratio curves of this kind have been plotted in Fig. 6, using as abscissas the ratios of the time constants of the circuits to the time interval of excitation. All of these curves are plotted for the case in which an alternating electromotive force of constant value is impressed for a definite interval T_e in a circuit which is resonant to the impressed frequency. At the end of the interval T_e, the impressed electromotive force ceases and the oscillation, which has been building up, then dies down as the energy stored in the circuit during the interval T_e is gradually dissipated. If the detector resistance is proportioned as in equation (2), one half of the total energy delivered to the antenna circuit is delivered to the detector and the other half is partly expended in the wasteful resistance and partly re-radiated.

In Fig. 6, curve A shows the ratio between the value which the current has attained at the end of the interval of excitation T_e and the ultimate or steady-state value of the current under the same electromotive force if long sustained. Curve B shows the ratio between the power expenditure in the circuit resistance at the end of the interval T_e and the power expenditure which would occur in the resistance under the steady-state current. For example, if the time constant of the circuit is equal to 0.2 of the interval of excitation, the current at the end of the interval of excitation has attained 0.993 of the steady-state value and the power expenditure in the resistance and hence the power delivery to the detector has attained to 0.986 of the steady-state value. The equation of curve A is

$$i/I = 1 - \epsilon^{-T_e/T_c} \tag{8}$$

Curve C shows the ratio of the energy actually expended in the circuit resistance in the interval T_e,

while the electromotive force is still impressed in the circuit, to the energy which would be expended in the interval T_e by the steady-state current corresponding to the impressed electromotive force. The equation of this curve is,—

$$\frac{\int_0^{T_e} i^2 R\, d t}{I^2 R T_e} = 1 - \frac{1.5\, T_c}{T_e} + \frac{2\, T_c}{T_e}\, \epsilon^{-T_e/T_c} - \frac{T_c}{2\, T_e}\, \epsilon^{-2T_e/T_c} \quad (9)$$

$$= 1 - \frac{1.5\, T_c}{T_e} \quad \text{if } \frac{T_c}{T_e} < 0.5 \quad (9a)$$

$$= \frac{1}{3}\left(\frac{T_e}{T_c}\right)^2 \quad \text{if } \frac{T_c}{T_e} > 5. \quad (9b)$$

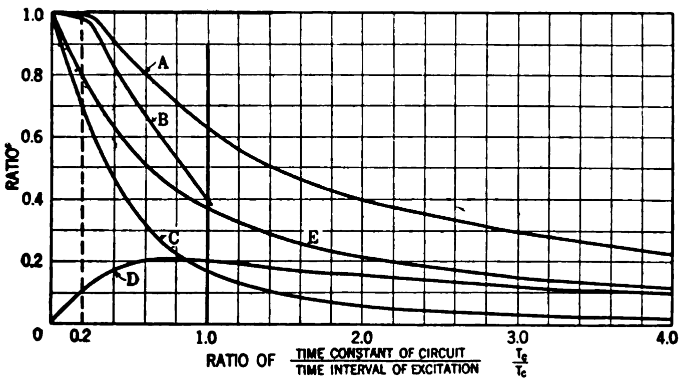

FIG. 6—CURRENT AND ENERGY RATIOS IN A RESONANT CIRCUIT

T_e represents interval of excitation

I " value of steady state current

A shows $\frac{\text{current at end of } T_e}{I}$

B " $\frac{i^2 R \text{ at end of } T_e}{I^2 R}$

C " $\frac{\int_0^{T_e} i^2 R\, d t}{I^2 R T_e}$

D " $\frac{\text{Energy stored at end of } T_e}{I^2 R T_e}$

E " $\frac{\text{Total energy delivered during } T_e}{I^2 R T_e}$

Curve D shows the ratio between the energy *stored* in the circuit at the end of the interval T_e, at which instant the impressed electromotive force ceases, and the energy which would have been expended in the circuit in the interval T_e, by the steady-state current. The equation of this curve is,—

$$\frac{\text{Energy, stored at end of } T_e}{I^2 R T_e} = \frac{T_c}{2\, T_e} \cdot (1 - 2\, \epsilon^{-T_e/T_c} + \epsilon^{-2T_e/T_c}) \quad (10)$$

$$= \frac{T_c}{2\, T_e} \quad \text{if } \frac{T_c}{T_e} < 0.2 \quad (10a)$$

$$= \frac{T_e}{2\, T_c}\left(1 - \frac{T_e}{T_c}\right) \quad \text{if } \frac{T_c}{T_e} > 5 \quad (10b)$$

The total energy which will eventually be expended in the resistances of the circuit as the result of the impressing of the resonant electromotive force for the interval T_e is the sum of the energy expended in the circuit resistances during the interval T_e (as shown by Curve C) and the energy stored at the end of the interval T_e (as shown by curve D). Curve E shows the ratio of this sum to the energy which would have been expended in the interval T_e by the steady-state current. The equation of Curve E is,—

$$\frac{\text{Total energy delivered to circuit}}{I^2 R T_e} = 1 + \frac{T_c}{T_e}\, (\epsilon^{-T_e/T_c} - 1) \quad (11)$$

$$= 1 - \frac{T_c}{T_e} \quad \text{if } \frac{T_c}{T_e} < 0.2 \quad (11a)$$

$$= \frac{T_e}{2\, T_c}\left(1 - \frac{1}{3}\, \frac{T_e}{T_c}\right) \quad \text{if } \frac{T_c}{T_e} > 5 \quad (11b)$$

The ratio of the total energy delivered to the circuit by a *slightly detuned* electromotive force which is impressed for a time interval T_e which is short in comparison with the time constant of the circuit, to the energy which would be *expended* in the circuit in the interval T_e by the steady-state detuned current varies greatly with the point at which the impressed voltage ceases. (See Fig. 5.) For example, if the detuned voltage is interrupted at the first current node, the ratio of the energy delivered to the circuit to the energy which would be expended in the circuit by the steady-state detuned current is substantially 2 to 1. While if the voltage is interrupted at the first antinode of the current and if the time constant is long in comparison with the interval of excitation, the ratio becomes substantially $\left(2 + \frac{2\, T_c}{T_e}\right)$ to 1.

Hence, we may draw the following conclusions relative to the energy delivered to a circuit by a detuned voltage which is impressed for an interval T_e. First: If the time constant of the circuit is less than 0.2 of the interval of excitation, the ratio between the total energy delivered to the circuit by the detuned electromotive force and the energy which would be expended in the circuit in the interval T_e by the steady-state detuned current corresponding to the detuned voltage may be taken as roughly 1 to 1. Second: If $T_c > 5\, T_e$, the ratio will lie between 2 and

$\left(2 + \frac{2\,T_c}{T_e}\right)$ to 1, depending on the point of the beat at which the impressed voltage ceases. For the unfavorable cases the ratio may be written as roughly

$$\frac{2\,T_c}{T_e}.$$

From the data in the above paragraph and that to be obtained from Curve E of Fig. 6, we may now draw conclusions as to the conditions under which, and the extent to which, the selective coefficient for the interval of excitation will differ from the steady-state-selective-coefficient. If the time constant of the circuit is less than one tenth of the interval of excitation, the selective coefficient for the interval of excitation may be taken as approximately equal to the steady-state-selective-coefficient. An inspection of Fig. 5 and Curve E of Fig. 6 shows that if the time constant of the circuit has the greatest length allowable in sustained wave systems, namely a length equal to 0.2 of the interval of excitation, the excitation-interval-selective-coefficient will be somewhat less than 0.8 of the steady-state-selective-coefficient. If the time constant of the circuit were increased until it equaled in length the interval of excitation, the excitation-interval-selective-coefficient would not exceed 0.2 of the steady-state-selective-coefficient. That is, while an increase in the time constant from $0.2\,T_e$ to T_e, or an increase of 5 to 1 in the time constant, will increase the steady-state-selective-co-efficient in the ratio of 25 to 1, it increases the excitation-interval-selective-coefficient in the ratio of less than 5 to 1.

After the time constant of the circuit has been made as long as the interval of excitation, a further increase in the length of the time constant produces only a moderate increase in the value of the excitation-interval-selective-coefficient. If the time constant is 5 or more times as long as the interval of excitation, the excitation-interval-selective-coefficient is equal to $1/4\,(T_e/T_c)^2$ of the steady-state-selective-coefficient.

$$S_c = \frac{1}{4}\left(\frac{T_e}{T_c}\right)^2 (2\,\pi\,f_r\,P_d\,T_c)^2 \text{ if } T_c > 5\,T_e$$

$$S_c = \frac{1}{4}\,(2\,\pi\,f_r\,P_d\,T_e)^2 \qquad \text{if } T_c > 5\,T_e \quad \textbf{(12)}$$

The conclusions are:

In sustained wave systems the time constant should not be longer than 0.2 of the interval of excitation.

If $T_c = .2\,T_e$

Excitation-interval

$$S_c = 0.8 \text{ (Steady-state } S_c\text{) roughly}$$
$$= 0.8\,(2\,\pi\,f_r\,p_d\,T_c)^2 \quad \text{“} \quad \textbf{(13)}$$
$$= 0.032\,(2\,\pi\,f_r\,p_d\,T_e)^2 \quad \text{“} \quad \textbf{(13a)}$$

In rapidly damped spark systems (in which T_c may be greater than $0.2\,T_e$) the excitation-interval-selective-coefficient is only moderately increased by making T_c greater than T_e.

If $T_c = T_e$

Excitation-interval

$$S_c = .2\,(2\,\pi\,f_r\,p_d\,T_c)^2 \text{ roughly} \quad \textbf{(14)}$$
$$= .2\,(2\,\pi\,f_r\,p_d\,T_e)^2 \quad \text{“} \quad \textbf{(14a)}$$

11. *Feasibility of obtaining tuning inductances with time constants of* 0.04 *seconds or longer.* The time constant (defined as equal to L/R) of the average inductance found in electrical laboratories and in radio receiving sets is of the order of 0.0001 to 0.001 second. Accordingly, the question arises as to the feasibility of obtaining special tuning inductances whose resistances will be low enough to permit of making the time constant of the receiving circuit as long as 0.01 seconds.

In considering this question, let us suppose that substantially all of the inductance of the antenna receiving circuit must be provided for in the loading and tuning coil. Suppose further that of the total wasteful resistance, one-half may be allowed in the tuning coil. If the further assumption is made that the total wasteful resistance is not to exceed the radiation resistance, then the time constant of the tuning inductance (defined as L/R) is equal to $L \div 1/2\,R_r = 2\,L/R_r$. But the time constant of the oscillatory circuit itself (defined as $2\,L/R$) is $2\,L \div 4\,R_r = L/2R_r$. Therefore under the assumed conditions, the time constant of the tuning inductance (L/R) must be four times as great as that of the receiving circuit, or the time constant of the tuning coil must be at least 0.04 seconds.

Calculations indicate that it may be feasible to construct tuning inductances having time constants as long as 0.04 second at the lower frequencies (15,000 cycles).

12. *The combination of antenna height and area and resonant frequency which will give the highest selective coefficient for a given time constant.* From equation (7) it is seen that a high selective coefficient may be obtained by using a long time constant and a high frequency. It has been shown that other considerations prohibit the use of a time constant longer than 0.01 second. From equation (6) it is seen that the time constant of 0.01 second may be obtained either at a high or a low frequency. For example, if a given resonant frequency is used in antenna A, and if in antenna N it is desired to use a frequency (n) times as great, for the purpose of obtaining a selective coefficient n^2 times that of A, the time constant of N may be made the same as that of A by making the product of $a \times h$ (area $\times$ height) for antenna N $(1/n)^4$, times as great as the ($a\,h$) product of antenna A. That is, if the time constant is to be retained unchanged, then as the resonant or operating frequency is increased, lower heights or lower areas must be used. If the frequency is doubled, ($a\,h$) must be made 1/16 as great.

It should be noted that while equation (7) is not perfectly general but applies only to highly oscillatory circuits, yet this fact does not set an upper limit to the frequency at which equation (7) may be used. This may be seen from the expression for the ratio of the critical resistance of a circuit to its actual resistance, namely:—

$$\frac{R_c}{R} = 2\,\pi\,f_r\,T_e \qquad (15)$$

That is, if two circuits have the same time constant, the circuit having the higher resonant or natural frequency is the more highly oscillatory circuit.

It follows, then, that the upper limit to the frequency which should be used will be set by considerations other than those arising from the selective properties of the receiving circuit. The limit will be set by considerations such as—the greater attenuation with distance suffered by the higher frequencies, or the difficulty of obtaining satisfactory sustained wave generators for the higher frequencies, or by the smaller power abstracting efficiency of the antennas at the higher frequencies.

From the equations (6) and (7) may be plotted the two curves shown in Fig. 7. Curve ($a\ h$) shows the $a\ h$) product which should be used with any frequency in order to obtain a time constant of .01 sec. The equation of this curve is

$$a\,h = \frac{3\,s^3}{16\,\pi^3\,k\,T_c\,f_r^{\,4}} \qquad (16)$$

Assuming k to equal 2, (or $R_t = R_r + R_w + R_d = 4\,R_r$) and substituting $T_c = .01$, this equation becomes,—

$$a\,h = \frac{8.15\ 10^{30}}{f_r^{\,4}}\ \text{cu. cm.}$$

Curve S_e of Fig. 7 shows the selective coefficient to a frequency detuned by 1 per cent, when the antenna is proportioned to have a time constant of 0.01 second. The equation of the curve is

$$S_e = (2\,\pi\,f_r\,p_d\,T_c)^2 \qquad (7)$$

It should be noted that while the selective coefficient varies directly as the square of the resonant frequency, the power which may be abstracted by two antennas from impinging waves of a given in-

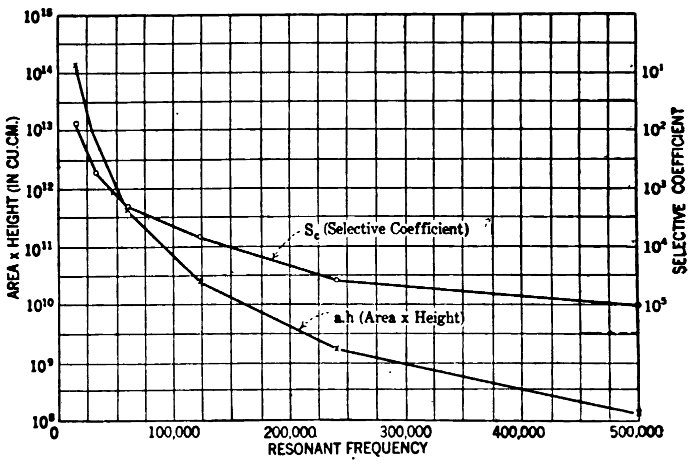

Fig. 7—Resonant Frequency Versus Dimensions and Selective Coefficient of an Extended Antenna Having a Time Constant of 0.01 Second

Interferent station detuned 1 per cent.
Note: The spotted points alone are exact.

tensity but of different frequencies varies inversely as the square of the frequencies. In other words, the effectiveness of a receiving antenna as an abstracter of energy in a power transmission system varies inversely as the square of the frequency or directly as the square of the wave length. The demonstration of this proposition is given in the next section.

(To be Continued)

PORTABLE REFLECTOMETER

Some time ago there was described a new type of reflectometer, suitable for measuring the reflection of light from walls, ceilings and other objects, which had been developed at the Bureau of Standards. Incidentally, measurements made with this instrument showed that there had been serious errors in the values previously accepted for the reflection factors of most materials. The development of this instrument and the publication of the values obtained with it stimulated considerable interest in this subject and a number of somewhat similar reflectometers have since been made up by other experimenters. All of the results obtained have corroborated those obtained at the Bureau of Standards.

The instrument then described depended upon computations which were somewhat complex and considerable precautions were necessary in its use in order to obtain correct values. In order to obviate these difficulties, a different type of instrument has been developed which depends on the same fundamental principles as the original one but is more simple in operation. The new instrument was described before the Convention of the Illuminating Engineering Society last month and the description will be published soon in the transactions of that Society as well as in the scientific papers of the Bureau. The description of the original instrument has already been published as Scientific Paper No. 391 and also in the *Journal of the Optical Society of America*, Volume 4, No. 1, January, 1920.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

A. I E. E. PUBLICATION POLICY

At a conference held October 6 by the Publication and Finance Committees of the Institute certain changes in the Institute's policy regarding the monthly JOURNAL and annual TRANSACTIONS were recommended, as embodied in the following resolutions:

VOTED to recommend to the Board of Directors that commencing with the volume of Institute TRANSACTIONS covering the year 1921, the practice of furnishing a copy of the TRANSACTIONS to each member of the Institute be discontinued, and that copies be furnished to all members who subscribe in advance at a price to be determined later, possibly 5. per year; the edition to be determined by the advance subscriptions received, with a reasonable allowance for stock to meet future demands.

Voted that commencing with the January 1921 meetings of the Institute a resume of the discussion at each meeting be printed in the JOURNAL from month to month, so that members who do not obtain the TRANSACTIONS will have this discussion in their JOURNAL.

These recommendations were considered by the Board of Directors at its meeting held in Philadelphia, October 8, at which time the recommendations were approved in principle and the Board directed that a statement regarding the matter be published for the information of the membership.

The purpose of the proposed change is the elimination of the enormous waste, which has been discussed by Institute members for the past twenty years, caused by the duplication of expense in printing twice, practically all the papers presented at Institute meetings, once in the monthly JOURNAL and again in the annual TRANSACTIONS and furnishing copies of both publications to all members.

The immediate occasion for the action may be traced directly to the great increase in the cost of carrying on the various Institute activities, particularly the increased costs of paper, printing, and binding, which have increased more than 100 per cent in five years. For example, the annual TRANSACTIONS for the year 1916 actually cost $1.92 per copy, whereas a close estimate of the cost of printing the 1920 TRANSACTIONS is $3.89 per copy; the amount of material being practically the same in both volumes, and the 1920 edition being considerably increased over the 1916, which ordinarily would result in a decrease in the cost per copy instead of an increase of 103 per cent.

The cost of carrying on practically all the other activities of the Institute has also increased, although not to the same degree as indicated above. It is obvious, therefore, that it is impossible to continue the Institute activities on the old basis without an increase in revenue. The two committees referred to and the Board of Directors have therefore decided that instead of recommending an immediate increase in dues or a decrease in activities, that the policy which is in effect in many other technical societies of making an additional charge for the annual bound volume to be established; thus in effect increasing the dues, but only for those members who desire the annual TRANSACTIONS in addition to the monthly JOURNAL.

It will be noted that the change will not apply to the 1919 and 1920 TRANSACTIONS. The former volume has been unavoidably delayed due to the congestion in the printing industry since the strike which began in the Fall of 1919. It has now been completed, however, and distribution was commenced early in October and will be completed during the early part of November. The 1920 volume will also be delayed as the available funds are not sufficient to provide for the completion of the volume in the immediate future.

A. I. E. E. MEETING IN CHICAGO

On Friday, November 12, 1920, the American Institute of Electrical Engineers will hold its 365th meeting under the auspices, jointly, of the Chicago Section and the Protective Devices Committee. The Electrical Section of the Western Society of Engineers will participate.

The technical session at which four papers will be presented on the subject of "Lightning Protection," will be held at 7:30 p. m. at City Club, 315 Plymouth Court. This session will be preceded by an informal reception at 5:15 p. m. and an informal dinner ($2.50 per plate), also at the Club rooms, at 5:45 p. m. The rooms of the Western Society of Engineers, 1735 Monadnock Block, have been designated as Institute headquarters and the Board of Directors and various scheduled committees will hold their meetings there during the afternoon.

PROGRAM

3:00 p. m.—Board of Directors, Western Society of Engineers' Rooms, 1735 Monadnock Block.
5:15 p. m.—Informal Reception, City Club, 315 Plymouth Court.
5:45 p. m.—Dinner, City Club.
7:30 p. m.—Technical Session, City Club,

1. Lightning Arrester Spark Gaps—II. By C. T. Allcutt, of the Westinghouse Electric & Mfg. C.
2. Life and Performance Tests of *O F* Lightning Arresters. By N. A. Lougee, of the General Electric Co.
3. Studies in Lightning Protection on 4000-Volt Circuits—II. By D. W. Roper, of the Commonwealth Edison Co.
4. Electrostatic Condensers. By V. E. Goodwin, of the General Electric Co.

FUTURE A. I. E. E. MEETINGS

At its meeting in Philadelphia, October 8th, the meetings and Papers Committee arranged for this season's Institute meetings as follows:

November Meeting, Chicago.
January Meeting, Cleveland.
February, Midwinter Convention, New York.
March Meeting, New York.
April Meeting, Pittsburgh.
May, Annual Meeting, New York.
June, Annual Convention, Salt Lake City.

THE PHILADELPHIA MEETING

The 364th meeting of the A. I. E. E. was held in Philadelphia, Pa., October 8, 1920, at the Bellevue-Stratford Hotel. The registered attendance was 198. The meeting consisted of a technical session in the afternoon and a celebration of the centenary of the discoveries of Oersted, Ampere, Arago and Davy in the evening. An informal dinner was served in the ballroom of the hotel at 6 p. m., after which President Berresford made a brief address in regard to the policies and activities of the Institute.

Technical Session

The afternoon session was called to order by President Berresford, and the first paper, *Economic Study of Secondary Distribution*, by P. O. Reyneau and H. R. Seelye, was abstracted by Mr. Reyneau. This was followed by the presentation of the paper, *Electrical Demand Measurements*, by P. A. Borden, which was read by the author.

A discussion of the two papers followed which was participated in by W. I. Slichter, D. W. Roper, Paul M. Lincoln, C. I. Hall and W. H. Pratt, with closure by the authors.

Evening Session

The evening session was devoted to the celebration of the early electrical discoveries, of Ampere, Arago, Davy and Oersted, the speakers being Dr. Elihu Thomson and Dr. M. I. Pupin. These addresses will be published in an early issue of the Journal. Replicas of the apparatus used by the pioneer discoverers were prepared and demonstrated by Prof. Harold Pender during the session.

A. I. E. E. DIRECTORS' MEETING
OCTOBER 8, 1920

The regular monthly meeting of the Board of Directers of the American Institute of Electrical Engineers was held at the Bellevue-Stratford Hotel, Philadelphia, on Friday, October 8, 1920, at 10:30 a. m.

There were present: President A. W. Berresford, Milwaukee; Past President C. A. Adams, New York; Vice-Presidents, Charles S. Ruffner, New York, L. T. Robinson, Schenectady, E. H. Martindale, Cleveland; Managers W. A. Hall, Atlantic, Mass.. W. A. Del Mar, W. I. Slichter, E. B. Craft, New York, F. D. Newbury, Pittsburgh, H. B. Smith, Worcester, J. F. Lincoln, Cleveland; Treasurer George A. Hamilton, Elizabeth, N. J.; Secretary F. L. Hutchinson, New York.

A report was presented of a meeting of the Board of Examiners held September 27, 1920; and the actions taken on applications at that meeting were approved. Upon recommendation of the Board of Examiners the following action was taken upon pending applications: 22 Students were ordered enrolled; 157 applicants were elected to the grade of Associate; 10 applicants were elected to the grade of Member; 3 applicants elected to the grade of Fellow; 37 applicants were transferred to the grade of member; 3 applicants were transferred to the grade of Fellow.

The action of the Finance Committee in approving monthly bills amounting to $16,153.03 was confirmed.

Upon recommendation of the Finance Committee, a budget covering the activities of the Institute for the appropriation year commencing October 1, 1920, was approved.

The Meetings and Papers Committee reported upon plans in progress for the following meetings: Chicago, November 12; Cleveland, January (date to be decided later); New York, Midwinter Convention, February 23-25; New York, March 11; Pittsburgh, April 8.

Mr. Bancroft Gherardi was appointed to succeed the late Dr. Samuel Sheldon as one of the Institute's representatives on the Board of Trustees of the United Engineering Society.

The following committee appointments made by the President were announced: Law Committee—H. H. Barnes, Jr., Chairman, succeeding Dr. Sheldon; Special Committee on Geographical Divisions and Election Procedure—F. L. Hutchinson, succeeding Dr. Sheldon; Library Committee—W. I. Slichter, to succeed Dr. Sheldon as Chairman, and E. B. Craft as member.

The Committee on Geographical Divisions and Election Procedure presented a progress report, outlining tentatively a division of the membership into ten geographical districts and transmitting suggested changes in the by-laws.

It was voted to hold the next meeting of the Board of Directors in Chicago on the date of the Institute meeting, Friday, November 12.

The Standards Committee submitted revised standardization rules which the Board directed to be printed and published as "Standards of the American Institute of Electrical Engineers".

A petition from the Utah Section for an extension of territory was granted.

A memorial minute was adopted in recognition of the eminent services of Dr. Samuel Sheldon, Past-President of the Institute, who died in Middlebury, Vermont, September 4, 1920, and whose services to the Institute and the engineering profession generally were outlined in the obituary notice published in the October issue of the Journal.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matter may be found in this and future issues of the Journal under suitable headings.

MEMORIAL EXERCISES TO DR. SAMUEL SHELDON

Memorial exercises to the late Dr. Samuel Sheldon, Past-President of the Institute, and Professor of Electrical Engineering and Physics at the Polytechnic Institute of Brooklyn, will be held in the Auditorium of the Engineering Societies Building, 33 West 39th Street, New York, on Wednesday evening, November 17, 1920 at 8:30 o'clock. President Arthur W. Berresford will preside and addresses on Dr. Sheldon's life and work will be delivered by his close professional friends. The committee which is planning these exercises is headed by Mr. T. Commerford Martin and includes the following professional associates of Dr. Sheldon: Messrs. Edward D. Adams, Alfred D. Flinn, William N. Dickinson, Bancroft Gherardi, Erich Hausmann, C. O. Mailloux, Calvin W. Rice, Charles A. Terry and Calvert Townley. Representatives of the Corporation, Faculty, Alumni and Students of the Polytechnic Institute are cooperating with the foregoing committee. Ladies are invited.

1921 ANNUAL CONVENTION— SALT LAKE CITY

At a meeting of the Board of Directors of the A. I. E. E. held in Philadelphia, October 8, it was decided to hold the 1921 Annual Convention jointly with the Pacific Coast Convention, at Salt Lake City, Utah, during the week beginning Monday, June 20,

The movement to hold the convention at Salt Lake City started at the Pacific Coast Convention held in Portland, Oregon, July 21-24; at the convention session which was devoted to a discussion of Institute activities a resolution was unanimously adopted requesting the Board of Directors to consider holding the 1921 Annual Convention and the Pacific Coast Convention jointly, in Salt Lake City. Later this action was heartily endorsed by the Utah Section of the Institute and other organizations in Salt Lake City.

The principal argument in favor of combining the two conventions, as advanced at the Portland convention, was the desirability of bringing the eastern and western members of the Institute together occasionally for an interchange of ideas, in-

stead of holding two conventions each year, namely, the Annual in the eastern portion of the country, attended by very few of the far western members, and the Pacific Coast Convention, attended by only a few eastern members. The records show that no Annual Convention of the Institute has ever been held west of Omaha, and none west of the Mississippi River since the St. Louis Convention in 1904.

The Directors also had before them a cordial invitation from the Toronto Section of the Institute to hold the 1921 Annual Convention in the City of Quebec. The locations of the Annual Conventions for the past several years—practically all in the New England and Middle States—strongly supported the argument in favor of a western location for next year's meeting; and while appreciating the fact that the attendance from the members in the East will probably not be great, the Board decided to accede to the wishes of the membership located in the Pacific Coast and Rocky Mountain States as unanimously expressed at the Pacific Coast Convention in Portland, and otherwise by resolutions and other communications.

NATIONAL STANDARDIZING BODY ORGANIZED IN AUSTRIA

There has been formed in Austria a national engineering standardizing body. It is called the "Normenausschuss der Osterreichischen Industrie" and is organized under the auspices of the "Hauptverband der Industrie Deutschosterreichs." The Secretary is Dr. Jaro Tomaides.

This is the tenth national standardizing body to be formed, the others being in Belgium, Canada, France, Germany, Great Britain, Holland, Sweden, Switzerland and the United States. With the exception of the British Engineering Standards Association, whose work dates from 1901, they have all been formed since the beginning of the European war.

NATIONAL RESEARCH COUNCIL

TO STUDY ELECTRICAL INSULATION PROBLEMS

The Division of Engineering of the National Research Council has entered into an extensive campaign to investigate the principles of insulation, a matter which is of vital importance to the electrical trade and to its consumers. A meeting of the Division's Insulation Committee was held recently at the laboratories of the Western Electric Company at 463 West Street. It was attended by nearly two score of the most prominent engineers in the country. The Chief Engineer of the Western Electric Company, Doctor F. B. Jewett who is chairman of the committee presided.

The Engineering Division for sometime past has been endeavoring to formulate a practical plan whereby cooperation between the universities, the industries and the National Research Council might be accomplished in attacking the problems involved in fundamental research upon insulating materials. The basic properties of insulating materials are not well understood. Just what are the things that make an insulating material serve its function of insulating things electrically are not known. In order to arrive at an understanding of why an insulator insulates, because of the tremendous magnitude of the problems involved, cooperative research seems necessary.

A preliminary meeting of this committee was held a year ago. At that time no definite plans were formulated that seemed feasible as methods of attack. At this meeting, however, it was decided that the first step is the gathering together of all the published and known scientific material relating to insulation. This is a tremendous undertaking, and the committee decided that a permanent salaried secretary should be engaged to carry on the compilation of the material which has already been published and to maintain continuity in the records and activities of the Committee. The committee also decided that it would attack the technical problems by providing some research men in the universities with funds and materials supplied by the industries, under the guidance of the National Research Council.

The scarcity of skilled and trained research men, who are capable of attacking these recondite insulation problems, is a matter of much concern to the Insulation Committee. An effort will be made to discover among the post-graduate students and the faculties of the universities, men who are able to do this work. The benefits to the electrical industry, if these questions are given satisfactory answer, will in all probability be so great that a measure of them in financial terms at this time would be extremely difficult. In fact, if made in terms of the vision of these far-seeing men, they would seem extravagant and altogether unbelievable.

The committee consists of 37 representatives from the electrical industries, the national engineering societies, the national scientific societies, the national manufacturing organizations and the universities and colleges of the country. Among those who attended the meeting were: Mr. C. E. Skinner, Westinghouse Electric & Manufacturing Co., Dr. Irving Langmuir, General Electric Co., Mr. Percy H. Thomas, Consulting Electrical Engineer, New York, Mr. William A. Del Mar, New York, Mr. D. W. Roper, Commonwealth Edison Co., Chicago, Ill., Dr. Clayton H. Sharp, Electrical Testing Laboratories, New York, Dr. John Johnston, Yale University, Professor Frederick Bedell, Cornell University, Professor A. E. Kennelly, Massachusetts Institute of Technology, Professor K. T. Compton, Princeton University, Mr. Edward D. Adams, Engineering Foundation, New York, Dr. Carl Hering, Consulting Engineer, Philadelphia, Pa., Mr. John M. Weiss, The Barrett Company, New York, Dr. Richard C. Tolman, Chemical Division, National Research Council, Washington, D. C., Dr. F. B. Silsbee, Bureau of Standards, Washington, D. C. and a number of others.

PROGRESS ON THE SAFETY CODE PROGRAM

Considerable progress has been made on the comprehensive program of safety codes being undertaken by a large number of organizations under the auspices and rules of procedure of the American Engineering Standards Committee. Following this regular procedure, each code is being formulated by a sectional committee, broadly representative of the interests concerned, and composed primarily of representatives designated by the various bodies interested in the particular code. The sectional committee is organized by one or more bodies designated for the purpose by the American Engineering Standards Committee and known as sponsors.

Sponsorships for the additional safety codes have been arranged as follows:

Construction Work. National Safety Council.

Electrical Fire Code. National Fire Protection Association.

Electrical Safety Code. Bureau of Standards.

Floor Openings, Railways and Toe Boards. National Association of Mutual Casualty Companies.

Lighting Code. Illuminating Engineering Society.

Lightning Protection. American Institute of Electrical Engineers and the Bureau of Standards.

Machine Tools. National Machine Tool Builders Association and the National Workmen's Compensation Service Bureau.

Mechanical Transmission of Power. National Workmen's Compensation Service Bureau, the International Association of the Industrial Accident Boards and Commissions, and the American Society of Mechanical Engineers.

Sanitation Code, Industrial. U. S. Public Health Service.

Stairways, Fire Escapes and Other Exits. National Fire Protection Association.

Textiles. National Safety Council and the National Association of Mutual Casualty Companies.

The following sponsorships have previously been announced:

Abrasive Wheels. The Grinding Wheel Manufacturers of the United States and Canada, and the International Association of Industrial Accident Boards and Commissions.

Foundries. American Foundrymen's Association and the National Founders' Association.

Gas Safety Code. Bureau of Standards and the American Gas Association.

Head and Eye Protection. Bureau of Standards.

Paper and Pulp Mills. National Safety Council.

Power Presses. National Safety Council.

Pressure Vessels, Non-fired. American Society of Mechanical Engineers.

Refrigeration, Mechanical. American Society of Refrigerating Engineers.

Woodworking Machinery. International Association of Industrial Accident Boards and Commissions and the National Workmen's Compensation Service Bureau.

The *Head and Eye Protection Code* has been completed, and the sponsor, the Bureau of Standards, has submitted the Code to the Main Committee for approval.

STANDARDIZATION OF ELEVATORS

Upon request of the American Institute of Architects and the Elevator Manufacturers' Association of the U. S., a conference of the various bodies interested in the question of the standardization of levators was called by the American Engineering Standards Committee to decide whether such standardization work should be undertaken, and if so, what the scope of the work should be. The conference was held in New York on September 21st, and was attended by representatives of the following organizations:

American Institute of Architects.
American Institute of Consulting Engineers.
American Institute of Electrical Engineers.
American Society of Mechanical Engineers.
American Society of Safety Engineers.
Bureau of Buildings (Manhattan).
Bureau of Standards.
Electric Power Club.
Elevator Manufacturers' Association of New York.
Elevator Manufacturers' Association of the U. S.
National Association of Building Owners and Managers.
National Fire Protection Association.
Supervising Architect's Office, U. S. Treasury Department.

After a full discussion, including such matters as platform sizes, speeds, accelerations, capacities, methods of test, pit and overhead clearances, well dimensions and hatchways, and safety provisions and appliances, the following resolution was unanimously voted:

RESOLVED: that this Conference fully recognizes the need and the desirability of standardizing such features of both passenger and material-handling elevators as capacities, platform sizes, and methods of test.

The relation of the standardization of the fundamental features of elevator to the elevator safety code now being formulated by the American Society of Mechanical Engineers, was fully considered and a committee was appointed to confer with the committee of the Society which is in charge of the code and arrange for cooperation.

A committee was appointed consisting of one representative from each body represented at the Conference to formulate plans for the organization of the work and to report its recommendations to the American Engineering Standards Committee.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

NEW YORK CITY AUTHORIZES INCREASE IN COMPENSATION OF ENGINEERING EMPLOYEES

Under a recent general readjustment of the salaries of municipal employees in the City of New York the compensation for all positions carrying a salary of less than $7500 per annum has been increased. In the case of salaries of less than $1500 the increase is at the rate of 22 per cent with a minimum of $200. In the case of salaries ranging from $1500 to $2500 per annum the increase is 20 per cent. To salaries upwards of $2500 per annum $500 has been added but salaries plus increases have been limited to a maximum of $7500.

The effect of these increases upon the compensation of the engineering force of the city as organized near the close of last year is shown in the following table, which also gives a comparison with the average compensation for the same positions as fixed before the shrinkage in the value of the dollar became pronounced. All of the positions are classified on the basis recommended by Engineering Council's Committee on Classification and Compensation.

Comparing the present average compensation with the compensation schedule proposed by the Committee, it will be seen that the average pay of Junior Aids and Junior Assistant Engineers under this scale is substantially greater than that tentatively recommended; that the average compensation for Aid is practically the same as that proposed by the Committee; that the average compensation for Senior Aid and Assistant Engineer is very close to the Committee's minimum; and that for the grades Senior Assistant Engineer, Engineer and Chief Engineer the average salary, after the allowed increases have been added and notwithstanding the appreciable betterment in the lower grades is still approximately $650 to $1,500 per annum below the minimum compensation proposed by the Committee.

Position	Number of Employees	Average Salary July 1, 1915	Average Salary After Aug. 20, 1920	Per cent increase
Chief Engineer (including Deputy Chief Engineer)	20	$7,270	$7,450	2
Engineer	50	3,850	4,470	16
Senior Assistant Engineer	86	2,850	3,420	20
Assistant Engineer	171	2,180	2,760	27
Junior Assistant Engineer	56	1,630	2,370	45
Senior Aid (Chief Instrumentman and Chief Draftsman)	64	1,700	2,440	44
Aid (Instrumentman and Draftsman)	285	1,500	2,180	45
Junior Aid (Junior Draftsman and Rodman)	150	1,030	1,720	67

FEDERATED AMERICAN ENGINEERING SOCIETIES

A. I. E. E. REPRESENTATIVES ON AMERICAN ENGINEERING COUNCIL

At the meeting of the Board of Directors of the A. I. E. E. held in Philadelphia, October 8, the following twelve members were appointed as the official representatives of the Institute upon the Am. Engineering Council, which is the governing body of the Federated American Engineering Societies, for the term beginning January 1, 1921, and also to represent the Institute at the organization meeting to be held in Washington, November 18-19, 1920:

Comfort A. Adams, Cambridge, Mass.
A. W. Berresford, Milwaukee, Wis.
H. W. Buck, New York, N. Y.
F. L. Hutchinson, New York, N. Y.
W. A. Layman, St. Louis, Mo.
William McClellan, Philadelphia, Pa.
L. F. Morehouse, New York, N. Y.
L. T. Robinson, Schenectady, N. Y.
Charles S. Ruffner, New York, N. Y.
Charles F. Scott, New Haven, Conn.
L. B. Stillwell, New York, N. Y.
Calvert Townley, New York, N. Y.

ADDITIONAL SOCIETY ACTIONS

The Joint Conference Committee takes pleasure in announcing five additional members of The Federated American Engineering Soceities:

Engineering Association of Nashville. On June 7, 1920 the Engineering Association of Nashville voted to become a Charter-Member of The Federated American Engineering Societies.

American Institute of Chemical Engineers. At its meeting of June 29, 1920, the American Institute of Chemical Engineers voted to join The Federated American Engineering Societies.

Engineering Societies of Buffalo. At the meeting of September 21, 1920, the Engineering Society of Buffalo voted, unanimously, that the Society become a Charter-Member of the Federated American Engineering Societies.

American Institute of Mining and Metallurgical Engineers. At its meeting of September 24, 1920, the Board of Direction of the American Institute of Mining and Metallurgical Engineers voted to become a Charter-Member of The Federated American Engineering Societies.

Society of Industrial Engineers. The Board of Directors of the Society of Industrial Engineers have voted to become a Charter-Member of The Federated American Engineering Societies.

CURRENT ENGINEERING TOPICS

MEETING OF BOARD OF SURVEYS AND MAPS

The new board of Surveys and Maps met with its advisory council on September 14th to receive reports of its committees and to appoint permanent members to the regular standing committees from the advisory council.

Owing to the fact that the time since the last meeting had been largely taken up by the vacation period in Government departments, only reports from the committees on Information, Technical Standards and Topographic Maps were ready for presentation.

The committee on information reported the results of its questionnaires sent to all Government map-making Bureaus which indicated that the Information Office should for the present carry on the work of indexing map data since it was feared that large amount of additional clerical work would be involved because of the change to the Harriman system at the present time. It urged the map-making Bureaus represented on the Board to furnish the Information Office with new data of maps as soon as these data could be prepared. A draft of a proposed popular bulletin on the Use of Mean Sea Level Datum for Spirit Level Valuation was submitted with the recommendation that it be prepared for publication. It was also announced that the Food Administration had presented the Information Office with about 100 copies of maps of countries of Europe and Asia.

In the report of the committee on Technical Standards the results of the committee's questionnaire were reviewed, it being pointed out that there was a sharply divided practise in this matter at the present time. Four of the Bureaus reporting employ the metric system, while eight use the English system; and it was unanimously recommended by the committee that the English system be adopted as standard practise. By English measurement is meant the scales upon which one inch on the maps bears an integral relation to feet or miles on the ground, as for example, 1000 feet to 1 inch, 2 miles to 1 inch, etc. By the metric measurement is meant the practise of employing "ratio" scales evenly divisible into one million such as 1:62500, 1:250,000, etcetera. The chairman of the advisory council has stated that when this comes before his council for recommendation a general questionnaire will be sent to as many interested engineers as possible, so that general engineering opinion may be obtained.

The committee on Topographic Maps made some specific recommendations which if followed out will be of value to hydraulic and drainage engineers and other technical users of maps.

The next regular public meeting will be held on the second Tuesday in November at ten o'clock in the Department of the Interior Building.

ACCOMPLISHMENTS UNDER THE FEDERAL WATER POWER ACT

When the Federal Water Power Act was approved on June 10th it concluded twelve years of effort for effective water power legislation. In accordance with the provision of the Act, the Secretary of War, Secretary of the Interior and the Secretary of Agriculture became a Commission to administer the Act. This Commission was not able to accomplish effective work for nearly a month after it was organized because its members were unable to arrange a common meeting time. At their first meeting, however, the Secretary of War was appointed chairman and Mr. O. C. Merrill, then chief engineer of the Forest Service, was appointed executive secretary. This put the Commission on a working basis and it immediately organized under Mr. Merrill's direction to take care of the applications for power permits which were already being received.

The work of the Commission was divided into engineering, accounting, statistical, regulatory, licensing, legal, and operation. The engineering division is regarded as the most important as it will make general investigations of the electric power industry, power sites, costs and developments. It will among other things report results of its examinations to Congress preparatory to construction work of the United States; will examine and revise plans for development of streams upon which applications for licenses are made; will consider construction plans

proposed by licensee; will when necessary make physical valuation of properties in rate-making proceedings; and when already existing plants are brought under the Act will fix the necessary stipulations as to maintenance, development and operation.

Up to the present time the following personnel have been assigned to the Commission: Lieut. Col. William Kelley, engineer officer; R. R. Rendell, Asst. engineer officer; Major L. W. Call, law officer and F. W. Griffith, chief clerk. With this small personnel the Commission has adopted a set of comprehensive regulations covering the procedure in connection with the securing of licenses and permits, and is handling applications at such a rate which if maintained will place under consideration before January 1st, 4,000,000 horse power.

While the regulations were being promulgated special hearings were held. Outside interests were invited to bring their recommendations before the Commission and a number of important changes resulted in the accepted principles. These included such questions as rental charges, amortization reserves, depreciation reserves, allocation of earnings and specifications covering the construction and maintenance of project works. In connection with these regulations the Water Conservation Committee of Engineering Council rendered a valuable assistance in response to specific inquiries from the Commission. These inquiries covered the subject of rental charges for water power licenses, including charges covering cost of Federal administration, use of Government lands and property, tribal lands within Indian reservations, the basis of expropriation above a specific rate of return, readjustment of charges, benefits from headwater improvement, allocation of earnings, depreciation and amortization. This committee of Engineering Council is still at the service of the Commission and is going deeply into the questions involved.

The regulations which were prepared at the September 3rd meeting were distributed about September 20th. Because of the wide variation in the applications which had been submitted to the Commission, they are all being returned to the applicants with a request that they be made to conform with the rules and regulations. This process will probably take considerable time because there are already over 60 applications, some of which involve a number of power sites. Up to October 1st four applications had been advertised.

The most important regulations so far promulgated are those numbered 9 and 10 dealing with permits and licenses respectively. They follow in complete form. Other regulations cover:

1. Definition of Terms.
2. Applications—General Requirements.
3. Applications for Preliminary Permits.
4. Applications for Licenses—Major Projects.
5. Applications for Licenses—Minor Projects.
6. Applications for Licenses—Major Projects Already Constructed.
7. Declarations of Intention.
8. Priorities and Preferences.
9. Permits.

a. Except as hereinafter provided, preliminary permits may be issued on the application of citizens, associations, corporations, States or municipalities desirous of obtaining licenses for the construction, maintenance or operation of dams, water conduits, reservoirs, power houses, transmission lines, or other project works necessary or convenient for the development and improvement of navigation, and for the development, transmission and utilization of power across, along, from, or in any of the navigable waters of the United States, or upon any part of the public lands and reservations of the United States (including the Territories), or for the purpose of utilizing the surplus water or water power from any Government dam.

b. Permits will be issued only for the purpose of enabling applicants to maintain their priorities while securing the data required for an application for license and will be for such periods, not exceeding a total of three years, as in the judgment of the Commission will be necessary for studying the proper location and design of the project; for making examinations, surveys, maps, plants specifications and estimates; for conducting stream measurements; for sinking test pits or making borings to determine foundations for dams or other structures; for securing a market for the power to be developed; for making financial arrangements; or for any other purpose necessary or desirable in the preparation of application for license.

c. Permits will not be issued for projects already constructed; for transmission lines alone; for projects of a power capacity of less than 100 horse power; for projects which, in the judgment of the Commission, do not come within the scope of its authority under the Act, or should be undertaken by the United States itself, or do not propose adequate schemes of development, or would unreasonably interfere with projects under permit, license or other authority theretofore granted; or for projects for which date sufficient for filing application for license are already available. Permit affecting any reservation will be issued only after a finding by the Commission that the proposed use will not interfere or be inconsistent with the purpose for which such reservation was created or acquired. Permits will not be issued until after the expiration of the publication period prescribed by the Act.

d. In acting upon applications for preliminary permits, and in determining preferences therefor, the Commission may in its discretion upon the request of any applicant or upon its own motion, hold hearing, order testimony to be taken by deposition, summon witnesses, or require the production of documentary evidence.

e. No charges will be made for permits, but permittees will be required as a condition of maintenance of priority, to perform such work and to make such studies and investigations, and such reports thereon, as in the judgment of the Commission may be necessary or desirable to enable both the applicant and the Commission to determine the feasibility, and the character and extent of development, which is proposed or which should be undertaken, which requirements will be expressed in the permit.

f. Upon a satisfactory showing of reasons therefore the Commission may authorize permittees to perform such construction work as may be necessary to maintain water rights under State Law, or as may be desirable in preparation for the construction of project works; but the granting of such authority shall not be deemed to have created any equities or to have established any rights beyond what would have been created or established had such authority not been given.

h. Each preliminary permit shall set forth the conditions under which priority shall be maintained and a license issued, and shall also set forth the essential terms and conditions of such license.

10. Licenses.

a. Except as hereinafter provided, licenses may be issued either in accordance with the provisions of preliminary permits or upon direct application therefor by citizens, associations, corporations, States or municipalities, for the purpose of constructing, operating, and maintaining dams, water conduits, reservoirs, power houses, transmission, and utilization of power across, along, from or in any of the navigable waters of the United States, or upon any part of the public lands and reservations of the United States (including the Territories), or for the purpose of utilizing the surplus water or water power from any Government dam.

b. Licenses will be issued for such periods, not exceeding fifty (50) years, as in the judgment of the Commission, will in each individual case, allow for the satisfactory development and operation of the project and protect the public interest, and shall remain in full force and effect for such periods unless surrendered or terminated as provided in these regulations or revoked as provided in the Act.

c. Licenses will not be issued for projects which, in the judgment of the Commission, do not come within the scope of its authority under the Act, or should be undertaken by the United States itself or do not propose adequate schemes of development, or lack satisfactory showing of financial ability, or would unreasonably interfere with projects under permit license, or other authority theretobefore granted, or would be opposed to the public interest. No license affecting the navigable capacity of any navigable waters of the United States will be issued until the plans of the dam or other structures affecting navigation have been approved by the Chief of Engineers and the Secretary of War. Licenses within any reservation will be issued only after a finding by the Commission that the license will not interfere or be inconsistent with the purposes for which such reservation was created or acquired. Licenses will not be issued until after the expiration of the publication period prescribed by the Act.

d. Licenses may be altered only upon mutual agreement between the licensee and the Commission. Any such alteration shall be made a part of the license and a substitute for the provision altered, but no such alteration shall operate to alter or amend or in any way whatsoever be a waiver of any other part, condition, or provision of the license.

e. Licenses may be surrendered only upon mutual agreement between the licensee and the commission and upon the fulfillment by the licensee of all obligations under the license, with respect to payment or otherwise, existing at the time of such agreement, and, if the project works authorized under the license are constructed in whole or in part, upon such conditions with respect to the disposition of such works as may be determined by the Commission.

f. Licenses may be terminated by written order of the Commission after such reasonable notice, not exceeding ninety (90) days, as the Commission may grant, if there is failure to commence actual construction of the project works within the time prescribed in the license, or as extended by the Commission. Under similar conditions and upon like

notice the authority granted under a license may be terminated with respect to any project works or separable part thereof covered by the license, if there is failure to begin construction of such project works or part thereof within the time prescribed in the license or as extended by the Commission; but no part of the project works shall be deemed separable for the purposes of this regulation unless so specified in the license.

g. Licenses may be revoked only through proceedings in equity instituted in a district court of the United States for a district in which some part of the project is situated, and in the manner provided in the Act.

(a) In case construction of the project works covered by the license, or of any specified part thereof, has been begun but not completed within the time prescribed in the license, or as extended by the Commission; or

(b) In case the terms of the license are violated by the licensee.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (SEPT. 1-30, 1920).

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

ADVERTISING THE TECHNICAL PRODUCT.

By Clifford Alexander Sloan and James David Mooney. N. Y. and Lond., McGraw-Hill Book Co., Inc.; 1920. 365 pp., illus., 9 x 6 in., cloth, $5.

This book,—the work of two men experienced in advertising technical products, is a discussion of the more important factors of the problem. The subjects discussed are the economic elements of such advertising, the instruments available for it, the preparation of technical advertisements and advertising organizations. An interesting collection of actual advertisements, with critical comments, and a brief bibliography are included in the book.

FUEL OIL IN INDUSTRY.

By Stephen O. Andros. Chic., The Shaw Publishing Company, 1920. 214 pp., illus., tables, 9 x 6 in., cloth, $3.75.

The volume opens with a discussion of the physical and chemical properties of fuel oil, the principles of its combustion, a comparison of coal and oil as fuels and a description of "colloidal" fuel. This is followed by chapters on the storage and distribution of oil, methods of heating, straining and pumping, on the arrangement of boiler furnaces and on types of burners. The remaining portion of the book describes the applications of fuel oil in steamships, locomotives, iron and steel manufactures, heat treating, central stations, the sugar, glass and ceramic industries, and in heating buildings. The treatment is concise and practical rather than theoretical.

HANDBOOK FOR HEATING AND VENTILATING ENGINEERS.

By James D. Hoffman, assisted by Benedict F. Raber. Fourth edition, N. Y. & Lond., McGraw-Hill Book Co., 1920. 478 pp., illus., tables, 7 x 4 in., flexible cloth, $4.50.

Has Supplement: A Course of Instruction for Technical Schools with Questions, Problems and References. To be used in connection with the Handbook for Heating and Ventilating Engineers—Hoffman; 51 pp., 7 x 4 in., paper.

This volume is intended to fill the need of those engaged in the design and installation of heating and ventilating apparatus for a pocket-book covering the entire subject in simple form and containing the tables commonly used. The present edition has been entirely rewritten and reset, and considerably enlarged, to bring it into accord with present practise.

HYDRAULIC TABLES.

The elements of gaging and the friction of water flowing in pipes, aqueducts, sewers, etc.; flow of water over sharp-edged and irregular weirs and the quantity discharged. By Gardner S. Williams and Allen Hazen. Third edition, revised N. Y., John Wiley and Sons, Inc.; Lond., Chapman and Hall, Ltd., 1920. 115 pp., illus., plates, tables, 9 x 6 in., cloth, $2.

The third edition of these well-known tables has been carefully corrected and revised in minor points, and a new chapter has been added, in which the additional data that have accumulated during the fifteen years since these tables first appeared are examined to ascertain whether changes or adjustments in the formula are needed.

WINGS OF WAR.

An Account of the Important Contribution of the United States to Aircraft Invention, Engineering, Development and Production during the World War. By Theodore Macfarlane Knappen, with an introduction by Rear-Admiral D. W. Taylor. N. Y. & Lond., G. P. Putnam's Sons, 1920. 289 pp., plates, 8 x 6 in., cloth, $2.50.

The story of the United States army aircraft production program is essentially one of confident hopes, bitter disappointments, failures and successes such as inevitably attend the creation from nothing of an immense industrial organization. Until now, the history of this undertaking is chiefly found in the voluminous reports of investigating committees, which over-emphasize the failures and undervalue the successes. The present book is an attempt to supply a less one-sided account of the army air effort, one which will give a readable report of the problem, the methods used for its solution and the net results obtained.

THE OWNERSHIP AND VALUATION OF MINERAL PROPERTY.

Being an Elementary Treatise on the Nature of Mineral Interests and Royalties, and the Correct Method of Valuing such Property for the Purposes of Sale, Probate, and Rating and Taxation, together with a Statement of the Law relating to Rating and Taxation. By Sir R. A. S. Redmayne and Gilbert Stone. Lond. & N. Y., Longmans, Green and Co., 1920. 256 pp., 9 x 6 in., cloth, $4.50.

The primary object of this book is to assist the mining expert who desires to have available a statement of the interests involved and the mode of valuing those interests in the mining industry generally. The work consequently contains, in addition to chapters on royalties and valuation, a general explanation of the law relating to mining interests, wayleaves and subsidence, and also the law relating to the rating and taxation of mineral properties.

PERSONAL

G. S. McKee has been appointed Manager of Production of the Canton, Ohio plant of the Timken Roller Bearing Company.

J. C. Stevens and R. E. Koon have announced their new consolidation under the firm name, Stevens and Koon, Consulting Engineers, with offices in the Spaulding Building, Portland, Oregon.

F. M. Bond, who for the past six months has been Manager of the Corticelli Silk Mills (Nonotuck Silk Company) at Leeds and Haydenville, Mass., has been appointed General Manager in charge of all of the mills of the company, with headquarters at Florence, Mass.

L. F. Wood, who for the past year and a half has been acting as instructor of technical graduates, in the Chicago Central Station Institute, educational bureau of the Commonwealth Edison Company, has accepted an associate professorship in the department of Electrical Engineering, Iowa State College, Ames, Iowa.

Ernest H. Billipp has been commissioned to visit South America to make a preliminary investigation for starting a new industry there. His work will include both making arrangements for obtaining a government concession, and solving the engineering problems encountered. He is expected to remain as consulting engineer after the project is under way.

H. W. Hough, for the past ten years Chief Electrical and Research Engineer for the Cleveland Electric Illuminating Co., has joined the staff of the Daniel M. Luehrs Co., Industrial Consulting and Construction Engineers, Cleveland, Ohio. Mr. Hough is an engineer of recognized standing in the central station industry, with experience both in the design and in the solution of the many industrial problems which are incident to the supply of light and power; and he has been closely associated with prominent engineers throughout the country in his work on various committees of state and national engineering societies.

OBITUARY

Richard Lamb, an Associate of the Institute since 1895 and a Member since 1913, died on October 18, 1920. Mr. Lamb was born in Norfolk, Va., in 1859. He received his early education at several schools in Virginia, and in 1883 finished the course at Brown University, Providence, R. I. From that time on he was engaged in active engineering work, for the most part in designing and building various plants, being appointed as Chief Engineer by such companies as the Brooklyn Dock and Terminal Co., the Chauncey Realty Co., and the Virginia Copper Co., Ltd. Later he went into business as Consulting Electrical and Civil Engineer with offices in New York City. Besides being a Member of the A. I. E. E., Mr. Lamb was a Member of the A. S. C. E. and the A. I. M. E.

Phillip Ewing Hart, Chief Electrical Engineer, Burma Mines, Ltd., was instantly killed by an accident on August 10, 1920, at Namtu, North Shan States, Burma, British India. Mr. Hart's home was at Mulgrave House, Sutton, Surrey, England, where he was born in 1878. His schooling included the Mechanical and Electrical Engineering courses at London University, after which he did engineering work for various companies in both America and England. When the war broke out he was in South America, engaged on an engineering project there as Resident Engineer; but he left this work to return to England and join the army as a private, later receiving a commission. He was in active service with the artillery for over two years, when he obtained a transfer to the Royal Engineers, still remaining in active service as forward roads officer, and receiving the commission of captain. He was awarded the Military Cross in 1918. Mr. Hart was a Member of the A. I. M. E. and an Associate of the A. I. E. E.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Lynn.—August 30, 1920. Annual business meeting, and election of officers as follows: Chairman, L. C. Loewenstein; Vice-Chairman, F. J. Rudd; Secretary-Treasurer, D. F. Smalley.

Providence.—October 8, 1920. Providence Engineering Society's Rooms. Election of officers as follows: Chairman, Walter C. Slade; Vice-Chairman, Nicholas Stahl; Secretary-Treasurer, Frederick N. Tompkins. Mr. G. H. Roosevelt, of the Railway & Traction Department of the General Electric Company presented a paper prepared by himself and Mr. C. M. Gilt on "Automatic Systems for Lighting and Railway Service." This paper was illustrated by lantern slides. Mr. R. J. Wensley, Switchboard Engineering Division, Westinghouse Elec. & Mfg. Co., also presented a paper, illustrated by lantern slides, on "Industrial Automatic Substations". Attendance 60.

St. Louis.—September 30, 1920. Dinner meeting, American Annex Hotel. Resolution passed favoring representation of engineering bodies of St. Louis in the Federated American Engineering Societies. President A. W. Berresford was the speaker of the evening and delivered an informal talk on Institute affairs. Attendance 109.

Seattle.—September 21, 1920. Banquet Room, Hotel Butler. Annual dinner and get-together meeting. Informal talks were given by Dr. C. E. Magnusson, a Vice-President of the Institute, and Willis T. Batcheller, the Section's delegate to the Annual Convention at White Sulphur Springs, W. Va. Attendance 50.

Worcester.—October 8, 1920. E. E. Bldg., Worcester Polytechnic Institute. Speaker: Mr. S. T. Dodd, of Schenectady, N. Y. Subject: "The Electrification of the Chicago, Milwaukee & St. Paul." Attendance 130.

PAST BRANCH MEETINGS

Brooklyn Polytechnic Institute.—October 4, 1920. Election of officers as follows: Chairman, Arthur H. Wehle; Vice-Chairman, John Gluck; Secretary, A. Marvin Liebowitz; Treasurer, William F. Strobel. Attendance 30.

Bucknell University.—Electrical Laboratory, October 4, 1920. Short talks were given by the President and Professors Irland and Hall concerning the branch, its advantages and the prospects for the coming year. Details of the Electrical Laboratory were then explained to the new men. Attendance 38.

University of California.—September 22, 1920. Speaker Mr. Nadon, of the Westinghouse Company. Subject: "Motion Picture Apparatus and Storage Batteries." Attendance 21.

October 6, 1920. Speaker: Mr. H. S. Dusenbery. Subject: "Electrical Stage Effects, Magic and Illusions." Attendance 85.

University of Missouri.—September 20, 1920. Engineering Building. Speaker: Professor A. C. Lanier. Subject: "The History and Work of the A. I. E. E." Attendance 100.

North Carolina State College.— September 28, 1920. Professor Browne and Capt. Cox of the electrical engineering department, were present and gave a demonstration of wireless telephony and telegraphy. Attendance 48.

Ohio Northern University.—September 15, 1920. Dukes Memorial. Business meeting. Informal talks by Professor Molitor of the Electrical Department, and Professor Brakes of the Mechanical Department. Attendance 16.

September 22, 1920. Dukes Memorial. Subjects: "The Engineer and The Society" by W. L. Lynde, and "Electric Locomotive" by Paul Rice, data taken from the April JOURNAL written by N. W. Storer. Attendance 36.

October 6, 1920. Dukes Memorial. Speaker: Professor C. C. Carpenter. Subject "The Modern Applications of Electricity." Attendance 25.

Purdue University.—September 21, 1920. Electrical Building. Business meeting followed by talks: "Benefits Derived from Student Membership of A. I. E. E.," by Professor A. N. Topping; "Importance of Becoming a Student Member of A. I. E. E.," by Professor D. D. Ewing; "Engineering Societies," by Dean Potter; "The Field of Electric Railways" by C. J. Harding. The remainder of the evening was spent in a social gathering. Attendance 280.

West Virginia University.—October 4, 1920. Mechanical Hall. Election of officers as follows: Chairman, Max Wilcoxen; Vice-Chairman, J. M. Frum; Secretary, Hudson Chandler; Treasurer, A. C. Price. A short lecture was given by Professor A. H. Forman. Attendance 13.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—James F. Elliott, Electric Controller & Manufacturing Co., Oliver Bldg., Pittsburgh, Pa.
2.—O. H. Horner, c/o Black & Veatch, 507 Interstate Bldg., Kansas ty, Mo.
3.—Wilfred Langille, Marion Station, Public Service Electric Co., Jersey City, N. J.
4.—H. S. Logan, 214 15th Street, Seattle, Wash.
5.—Alex. E. E. Mayo, Carnegie Institute of Technology, Pittsburgh, Pa.
6.—Leonard Morey, 1067 East 152nd Street, Cleveland, Ohio.
7.—P. J. Reese, 7th & Main Street, Royal Oak, Mich.
8.—L. F. Stoeltzing, 591 24th Street, Oakland, Cal.
9.—Richard G. Thomson, Alliance Power Co., Edmonton, Alberta, Can.
10.—J. Andre Wells, Western Electric Co., 463 West Street, New York, N. Y.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

MEN AVAILABLE

ELECTRICAL ENGINEER, 32, experience in line, substation and central station and industrial power work. Desires position with a public utility leading to executive responsibility or with a company holding or developing public utilities. E-2371.

TECHNICAL GRADUATE, 33, married, 8 years operating and supervising large and small coal carburated water gas properties, manager gas utility, community 7000, one year tool designing, automobile plant and one year purchasing and costs, auto trailer industry. Desires position with a future. Available on short notice. E-2372.

TECHNICAL GRADUATE, B. S. degree in Electrical Engineering. Three years experience as a draftsman, one year of which has been substation design. Would like position as Junior Engineer, but could consider position as draftsman if there is an opportunity to advance. Location N. Y. C. E-2373.

TECHNICAL GRADUATE, 34, married, Protestant. 18 years experience, machine shop, maintenance, drafting, designing, industrial substation layouts, conduits wiring diagrams, investigation reports on power plants, refrigeration plant improvements. Desire to connect with growing industrial organization. Prefer Newark, N. J., Conn. or Mass. E-2374.

GRADUATE ENGINEER, electrical, married. Six years experience with consulting engineer, and public utilities on utility problems (*i. e.* design and layout of distribution systems, appraisals, rate studies, etc.). Desires position with manufacturing company or consulting engineers on public utility industrial or sales engineering work. Vicinity of Cleveland, Toledo or Columbus preferred. E-2375.

GENERAL MANAGER, Public Utility Company, 18 years construction, operation, and development of small properties. Thoroughly versed in rate making and handling of municipal and public matters. Desires connection with consulting firm or larger utility. Age 39, married, present salary $4200. E-2376.

TECHNICAL GRADUATE, 24, 4½ years intimate acquaintance with power and substation equipment. Would like responsible position with some engineering concern vicinity Greater New York. Salary about $2500. Available immediately. E-2377.

ENGINEERING EXECUTIVE, 36, technical graduate. Experience in administration as well as in electrical, mechanical and industrial engineering lines. Now holding responsible position in production department of large manufacturing company. Will consider change for advancement. Salary dependent on opportunity to show results. E-2378.

COMMERCIAL ENGINEER, desires to make change. Graduate of University. Seven years electrical and mechanical experience and two years commercial experience in domestic and export transactions. Have worked for only the highest grade concerns. Wish to get into work which will give an opportunity to share in ownership or profits and management, having selected the experience so far obtained with this in view. E-2379.

GRADUATE ELECTRICAL ENGINEER, B. S. and E. E. degrees. Desires position with progressive firm as plant engineer. Twelve years experience in operation and testing of steam power plants, combustion and flue gas analysis, motor applications and wiring, heating and construction of factory buildings. Can furnish very best of references. E-2380.

ELECTRICAL ENGINEER, on construction or valuation work. Six years of railway, telephone, power, and distribution experience. Age 28. Salary expected $225 month. E-2381.

ELECTRICAL MECHANICAL ENGINEER, B. S. and E. E. Degrees. Ten years experience including railway electrifications, transmission systems, design and construction; central station construction and operation. Power application to industrial plants; electrical precipitation of smoke and

fume in industrial plant. Age 33, married. References. Salary $300. E-2382.

GRADUATE ELECTRICAL ENGINEER, (1909) married, age 31, desires position of greater responsibility in consulting and engineering. Has had factory and office experience, also erection, repair and executive experience with large industrial corporation. Capable of handling construction, erection and operation work. Salary $3000. Available at once. E-2383.

GENERAL SUPERINTENDENT, 10 years experience in charge of light and power work with large organization in East. Now employed but desires change. Married, age 33. Minimum salary $5000. E-2384.

ELECTRICAL ENGINEER, age 37, desires connection with industrial company, central station or manufacturing company. Technical graduate; eight years Westinghouse Service Department road and office duties. Five years factory test central station and large power and substation construction and maintenance. Location not a serious consideration. Prefer Middle or Southwest. E-2385.

POWER PLANT ENGINEER, design, construction, operation, technical graduate, 10 years' practical experience. Position desired in which thorough knowledge of power plant requirements will be useful. Also familiar with high tension lines and stations. Wish connection with sufficient prospects to warrant permanent location. 32, married; now with large engineering firm; wish to return to more specialized work. Available 30 days. E-2386.

ELECTRICAL ENGINEER, technical graduate. Broad engineering experience. Desires position with power company, consulting engineer, or construction company. Ten years' experience in power plant and substation work. Well versed in all subjects pertaining to the application of electricity for power purposes. Location Ohio or vicinity. Salary $3000. E-2387.

ELECTRICAL MECHANICAL ENGINEER, 24, technical graduate. Desires position with engineering construction and development firm, where opportunity for executive position in future is good. Foreign or domestic service. 1 year civil engineering, 4 years installation, manufacture and maintenance, 1 year assistant research engineer and inspector; present time power plant engineer. Available on short notice. E-2388.

ELECTRICAL ENGINEER, age 29, married. Desires position with firm handling or making industrial and power station equipment. Six years experience in purchasing, selling and handling of electrical equipment, also steam turbine and generator equipment. Salary $3000 per year. E-2389.

PUBLICITY & ADVERTISING EXECUTIVE, technical journalist. Formerly Assistant Editor of the largest Electrical publication in America and now Assistant Advertising Manager of one of the biggest electrical industries in U. S. Desires connection in similar capacity where initiative and executive ability assure position with unlimited future. Salary to start $2500. New York or vicinity. E-2390.

ENGINEER AND CERTIFIED PUBLIC ACCOUNTANT for assistant to high class business executive or connection with analytical organization. Exceptional experience in industrial analysis, factory cost accounting and system work, income tax procedure, engineering valuations, appraisals, investigations and reports. $7500 per year, minimum consideration. E-2391.

ELECTRICAL ENGINEER, desires business, engineering or sales position with growing concern. Experienced in manufacture test and correspondence and sale of electrical equipment. One year's active service as engineering and Radio officer in Air Service. Age 30, single. Available on short notice. E-2392.

ELECTRICAL ENGINEER, technical graduate with two years of varied test and development experience with large electrical power apparatus manufacturing concern, and one and one half years experience as chief tester with a small motor manufacturing concern, desires position with an industrial or power company. E-2393.

SALES MANAGER, or district manager, 40, married. E. E. degree. Sales and executive experience. $5000. E-2394.

ELECTRICAL ENGINEER, age 24, Graduate M. I. T. 1918. Desires change offering position with broader opportunities. Two years office and field work with large power corporation. Married. Salary $2500. Northern New York or New England States preferred. E-2395.

MANAGER AND ENGINEER, electric light and ice properties, age 40. Fifteen years experience construction, operation and managing small public service properties. At present with company operating properties in Texas. Wish to connect with larger company anywhere in the Southwest. E-2396.

ELECTRICAL ENGINEER, experienced in electrical installation and maintenance, including interlocking. No high-tension work. Eleven years experience in power, light, cranes, rotary convertors, pumps, engines, automatic control apparatus and circuit breakers. Available at short notice. E-2397.

GRADUATE ELECTRICAL ENGINEER, (M. E. E.) age 33, married. Nine years with present employer. Present work oversight of substation operation and care for large public utility. Familiar with line construction, maintenance, power and industrial plant design and construction. Wish to locate with consulting or contracting engineer, New York or New England with view to future financial interest. E-2398.

ELECTRICAL ENGINEER, 27, married, technical graduate, General Electric Test, experienced in design and distribution. At present assistant designing engineer with large company. Wish mid-western states location, with growing manufacturing concern. Initial salary $200 per month. E-2399.

SALES MANAGER, for manufacturing company desired by electrical engineer, 30, having nine years' broad business and engineering experience, possessing real sales and organizing ability and a forceful but pleasing personality. Salary $5000. plus small commission. Location preferred N. Y. C. E-2400.

TECHNICAL GRADUATE, age 28, desires position with chance for advancement. Not particular as to locality. Have had one year experience in transformer test of Westinghouse Electric and Mfg. Co. Two and one half years as Chief Electrician and in U. S. Navy. Available November 15, 1920. E-2401.

ELECTRICAL ENGINEER, 29, married, technical graduate 1915. At present Asst. Prof. Electrical Engineering. Desires commercial position in Middle West. Ability, capacity and willing worker. Broad engineering and business training. Future possibilities first, salary secondary. Available on reasonable notice. E-2402.

CONSTRUCTION ENGINEER, age 40, married, desire change to active construction work. Twenty years experience on central station and industrial work. At present designing automatic substation, 12000 kv-a., 33000 volts. Has had supervision of some of the largest electrical work in New England. Location New England or New York. Salary $3000. E-2403.

TELEPHONE TRANSMISSION INSPECTOR and Circuit Expert, one year college training, desires position with the Bell Telephone Company where initiative and ability are considered an asset. Age 28, good personality, married. Ten years' practical experience, highest references, salary $200. per month. E-2404.

YOUNG ELECTRICAL ENGINEER (1919) age 23, Spanish native tongue, with some technical and commercial experience, desires a position in Philadelphia. Willing to start at the bottom where there are good prospects of advancement. E-2405.

ELECTRICAL ENGINEER, 39, married, technically educated, eleven years broad experience on design construction and testing of power houses, substations and transmission lines. Desires opportunity for broader business training and development. E-2406.

GRADUATE ELECTRICAL ENGINEER. Twelve years experience designing, constructing, operating and appraising electrical properties, industrial plants, public utilities, etc. Position desired with progressive firm in North Central states capable of paying $3000 and up per year. Available after December 1st. E-2407.

PUBLIC UTILITY OPERATING MANAGER, Fellow A. I. E. E. desires engagement. Broad experience construction, operation and management light and power, railways and gas properties, steam and hydroelectric, large and medium size and high-tension transmission. Experienced with large organizations. Fine record public relations. American, perfect knowledge Spanish. E-2408.

OPPORTUNITIES

ELECTRICAL ENGINEER, one year out of college for sales work in New England. Sales experience not absolutely essential, but engineer of sales type, and who at the same time is capable from engineering standpoint. Work at present would consist chiefly of introducing line of electrical instruments. Man from Boston or vicinity preferred. Z-2310.

ELECTRICAL ENGINEERING GRADUATE to act as an engineering assistant in connection with preparation of estimates and proposals for service extensions to transmission and distribution system. Applicant can be a recent graduate or one with a few years' experience. Location Pa. Z-2307.

EDITOR, experience in power plant work. Application by letter only. Two men needed. Location N. Y. C. Z-2306.

SALESMAN AND EXECUTIVE to handle automobile department of an electrical concern, selling electric cars, industrial trucks and operate battery service station. Good position with great chance for development is open to the right man. Location N. Y. Z-2303.

EXPERIENCED GLASS MAN to take entire charge of Glass Works, both hand and machine bottles. Must understand machines making glass and the production end. Give full details of experience, age, salary expected and reference, in first letter. If not an A No. 1 glass man, do not answer this ad. Location Va. Z-2286.

LUBRICATING ENGINEER. Must be good citizen, know how to write the English language and have sufficient personality and address to talk with the Chief Engineers, Oilers and Presidents of the larger companies. Will be put into the grease plant for a few days. Then will compile from files every bit of information in regard to different industries. When information is compiled will be sent back on the road to two or three of the largest manufacturers of paper machinery to find out all he can in regard to lubrication and its bearing on paper machinery. Will call on two or three of the paper mills, at all times picking important ones so that the information will, first of all, be authentic and in the next place so that his call for help will serve as an introduction for this company, paving the way for future relations. When paper industry is completed it will be put into the hands of our salesmen and he will move on to the next industry. "What we are getting is, first of all, exact information; second, entree into plants where a salesman might need much longer time to get in; third, training for a real sales engineer because, when this man gets through with the principal industries, he will probably be better trained than almost any man in this country." Z-2274.

GRADUATE ELECTRICAL ENGINEER, preferably with some experience to prepare estimates for the expansion of the sub-station, and distribution system for new business and the preparation of proposals for contracts. Location Penna. Z-2275.

MECHANICAL ENGINEER familiar with design and operation of all forms of drying machinery and japanning ovens. Should have some intimate contact with this class of machinery, and especially in the construction of same. Location N. Y. City. Z-2276.

YOUNG ELECTRICAL ENGINEER with five or more years practical experience. Capable of working up proposals for equipment necessary for industrial plants of various kinds. Work is fairly broad, as business is transacted in foreign countries, buying the machinery and equipment here and shipping abroad, where we have our engineering staff who attend to erecting. Opportunity with great possibilities for the right man. Location New York City. Z-2277.

DRAFTSMAN with experience in electrical equipment for steel mills. Should also have power plant experience. Graduate Electrical Engineer desired. Location N. Y. City. Z-2268.

ELECTRICAL ENGINEER for power plant testing. Must have two years experience. Position permanent. Location New York City. Z-2262.

CHIEF ELECTRICIAN. Work consists of single and polyphase meter testing, motor testing, switchboard wiring, light and power wiring. General maintenance. Location Rhode Island. Z-2263.

MANAGER of Electric Department of Public Utilities. Location N. Y. Sate. Z-2241.

GRADUATE ELECTRICAL ENGINEER for power plant testing. Location Brooklyn, N. Y. Z-2244.

EXPERIENCED TRANSFORMER ENGINEER, one having experience on large power transformers. State in detail class of work previous experience has covered, and where at present employed. Location Canada. Z-2251.

ELECTRICAL ENGINEER. Young man, single, with good mechanical engineering knowledge. Chief duties would be electrical inspection of plant in the Nitrate Works. Good all-round man who would be able also to sell machinery when encountering any obsolete plant in Nitrate Works. Would also be needed at times in the absence of the Manager to take charge of office. Three years contract, passage and general living expenses paid. Location South America. Z-2231.

FOREMAN of electrical, mechanical instrument laboratory. Must be technical graduate or have had experience to substitute for such training. Also three section leaders with similar experience. Americans only. Four men needed. Location New Jersey. Z-2234.

RECENT GRADUATE, Electrical Engineer and Mechanical Engineer for development work on transmission and distribution for central station work in New York City. Z-2209.

MECHANICAL ELECTRICAL DRAFTSMAN with electric locomotive and multiple unit control car experience, as well as wiring and lighting equipment for steam cars. Location New York City. Z-2212.

MECHANICAL ENGINEER OR ELECTRICAL ENGINEER for sales work with battery company. Recent graduate will be considered. Location New York City. Z-2213.

ELECTRICAL ENGINEER for development of automatic regulating apparatus. Experience with voltage, current, speed regulation and water-wheel governors desirable. State age, experience and salary, and when available. Location Pa. Z-2216.

INSTRUCTORS in Electrical Engineering, two, will be appointed in February. Men with an unusually thorough grasp of fundamental electrical theory and a few years experience in engineering or teaching field are desired, although experience is not necessary. Appointees may pursue post graduate work. Location Wisconsin. Z-2220.

SALESMAN, preferably graduate Electrical Engineer with good sales experience but any engineer with broad sales experience will be considered. Company manufactures wires and cables. Location New York City. Z-2205.

DESIGNER for feed water heaters. Must have had experience in this line of work. Location Chicago, Ill. Z-2196.

MESSENGER for engineering company to look after office, etc. Should have high school education. Location New York City. Z-2203.

Long established technical school teaching courses in telegraphy and telephony, desires, for permanent position, a man capable of handling correspondence, and assisting in the preparation of textbooks on these subjects. Apply by letter, stating theoretical and practical training and salary expected. Z-2192.

TECHNICAL GRADUATE with 3 or 4 years experience, familiar with the design of electrical lay-out covering central station designing, underground duct lines, bus structures, conduit schedules, wiring diagrams and switchboard work. Location Mass. Z-2181.

MECHANICAL ENGINEER OR DESIGNER, air compressor expert, experienced in handling general experimental work independently; one able to figure cost and production. State fully experience, references and initial salary. Location New York City. Z-2185.

PHYSICIST who has had doctor's degree from two to five years. Experienced in general and electron physics. High grade man wanted. Location New Jersey. Z-2167.

ELECTRICAL ENGINEER for physical testing of lamp materials and general test on lamps. Must be able to take charge of laboratory. Graduate with two years experience. High grade man wanted. Location New Jersey. Z-2168.

RADIO AND RECTIFIERS TUBE ENGINEERS. Should be physicist on Electrical Engineering. Two men needed. One for radio tubes and one for rectifiers. Location New Jersey. Z-2169.

ORGANIC CHEMIST to have charge of chemical laboratory. Must be able to direct work and should have at least three years experience. In connection with experiment laboratory of U. S. Army, Air Service, Balloon & Airship Branch. Location Nebraska. Z-2175.

ENGINEER to look after mechanical end of power plant in China. Plant is about completed and will consist of two 2000 kw. Curtis Turbines. General Electric alternators 3000 volts, I and P Boilers (two batteries of 750 h.p.) Murphy stokers, superheaters, etc. Must have practical experience. Quarters will be furnished single man and $60. per month will be allowed married men for quarters. Location China. Z-2178.

PRODUCTION ENGINEER capable of superintending the construction and production of battery charging equipment, both for direct and alternating current. Must be familiar with rheostat, motor generator and switchboard design and capable of bringing the quality of our equipment up to the highest possible standard. Location Ohio. Z-1998.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED OCTOBER 8, 1920

ADAMS, REGINALD DOBSON, Electrical Engineer, Riccarton Borough Council, Riccarton, N. Z.
ALEXANDER, LOWELL M., Instructor in Physics, University of Cincinnati, Cincinnati, Ohio.
ALEXANDER, ROLAND B., Electrical Engineer, B. F. Goodrich Co., 206 W. Chestnut St., Akron, Ohio.
ALT, MILO S., Maintenance of Railway Converters& Substations, Iowa Railway & Light Co., Cedar Rapids, Iowa.
AMES, NORMAN B., Electrical Designer, The B. F. Goodrich Rubber Co., Akron, Ohio.
AMMANN, PHILIP G., Noma Motor Corp., 155 Avenue D, New York, N. Y.; res North Hackensack, N. J.
ANDREWS, BERTRAND HARDING, Supt. Hamilton Borough Council, Electric Power Station, Frankton Junction, Hamilton, N. Z.
ANTON, GEORGE, Electrician, Walker Electric & Plumbing Co., Lanett, Ala.
ARNOLD, HUGH T., Electrical Machine Designer, The Metropolitan Vickers Electrical Co., Trafford Park, Manchester, England.
AUSTIN, EUGENE H., Asst. Elec. Engineer, Lehigh Valley Coal Co., Wilkes Barre; res., 36 Wesley St., Forty Fort, Pa.
BARLOW, GODFREY F., Automatic Telegraph Supervisor, Great Northwestern Telegraph Co.; res., 212 Lee Avenue, Toronto, Ont.
BAUER, ERNST, Engineer, Electric Laboratory, U. S. Light & Heating Corp., Niagara Falls, N. Y.
BEAUDRY J. ARMAND, Engineer & Designer, Beland Electric Mfg. Co., 34 Southbridge St., Worcester, Mass.
BECKENBACH, FRANCIS H., Construction Dept., General Electric Co., Schenectady, N. Y.
BELFILS, GEORGES F., Asst. Chief Engineer, Societe Alsacienne de Constructions Mecaniques, Belfort, France.
BENNIS, STEPHEN, Cadet Engineer, New York Edison Co., Irving Place & 15th St.; res., 306 East 156th St., New York, N. Y.
BICKERSTAFF ERNEST, Distribution Foreman, Lake Coleridge Electric Supply, Public Works Dept., Addington, Christchurch, N. Z.
BRIGGS, ARTHUR P., Chief Engineer & Works Manager, Fabrica Tejidos Obregon, Barranquilla, Colombia, S. A.
BROWN, MICHAEL J., Engineering Dept., New York Edison Co., 15th St. & Irving Place, New York, N. Y.
BROWNSTEAD, JOHN P., Chief Engineer, Ashland Water Works, Ashland, Ky.

ASSOCIATE RE-ELECTED OCTOBER 8, 1920

CHESTERMAN, FRANCIS J., Chief Engineer, The Bell Telephone Company of Pennsylvania, 1631 Arch St., Philadelphia, Pa.

MEMBERS ELECTED OCTOBER 8, 1920

ADAMS, WILLIAM B., Chief Electrical Engineer, Central Power Dept., Rio Tinto Co., Huelva, Spain.
BERTRAND, PHILIP A., Secretary & General Manager, Grays Harbor Railway & Light Co.; res., 604 Essex Ave., Aberdeen, Wash.
DAVIS, ALTON F., Sales Manager, The Lincoln Electric Co., Cleveland, Ohio.
INGLEBY, HENRY S., Commercial & General Manager, Ingleby & Co., Ltd., 1 Albion St., Leeds, England.
MILLER, W. WEBSTER, Engineer, The Cutler-Hammer Mfg. Co.; res., 537 Tinton Ave., New York, N. Y.
MITCHELL, ROBERT B., Engineer & Manager, Glasgow Corporation Electricity Department, 75 Waterloo St., Glasgow, Scotland.
PLIMPTON, BENTLEY A., Sales Manager, The Locke Insulator Mfg. Co., Victor, N. Y.
POWEL, CHARLES A., General Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh; res., 634 So. Linden Ave., Pittsburgh, Pa.
WAGNER, GERALD J., Director of Public Service, City Hall, Grand Rapids, Mich.

MEMBER RE-ELECTED OCTOBER 8, 1920

LEWINSON, LEONARD J., Engineer of Lamp Tests, Electrical Testing Laboratories, 80th St. & East End Ave., New York, N. Y.

FELLOWS ELECTED OCTOBER 8, 1920

COLLIER, WILLIAM R., General Sales Manager, Georgia Railway & Power Co., Atlanta, Ga.
MITSUDA, RYOTARO, Doctor of Engineering, Electrotechnical Laboratory, Ministry of Communications, Tokyo, Japan.
SCHULZ, THOMAS NORBERG, Director of Electricity Works, Kristiania, Norway.

TRANSFERRED TO GRADE OF MEMBER OCTOBER 8, 1920

ANDERSON, STEWART W., Adjunct Prof. of Elec. Engg., Virginia Military Institute, Lexington, Va.
ANDREWS, SAMUEL, W., Asst. Plant Engr., Niagara Power Development, Hydro-electric Power Commission, Niagara Falls, Ont.
BAIRD, HOBART B., Electrical Engineer, United Gas & Electric Engineering Corp., New York, N. Y.
BALDWIN, JOHN R., Electrical Engineer, Republic Flow Meters Co., Chicago, Ill.
BLALOCK, GROVER C., Instructor in Electrical Engineering, Purdue University, Lafayette, Ind.
BOYAJIAN, ARAM, Development & Research Engineer, General Electric Co., Pittsfield, Mass.
CODE, ELDEN S., Sales Engineer & Switchboard Designer, Westinghouse Elec. & Mfg. Co., Seattle, Wash.
COSTELLO, W. H., Sales Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
DUSTIN, FRED G., President, Standard Electric Service Co.' Minneapolis, Minn.
FAWCETT, CHARLES DEVAN, Asst. Prof. of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa.
FAWELL, THOMAS A., Chief Draftsman, Anderson, Meyer & Co. Ltd., Shanghai, China.
FRIDAY, ELLSWORTH C., District Manager, Corliss Carbon Company, Chicago, Ill
GODDARD, RALPH W., Dean of Engineering, Professor of Electrical Engineering, New Mexico College of Agriculture & Mechanic Arts, State College, N. M.
GOETZENBERGER, RALPH L., Major, Ordnance Dept., U. S. Army, Frankford Arsenal, Philadelphia, Pa.
HAIL, JOSEPH C., Electrical -Engineer-in-Charge, Dept. of Electricity, City of Chicago Chicago, Ill.
KNOST, CHAS. P., Salesman, Westinghouse Elec. & Mfg. Co., New Orleans, La.
LUND, CHARLES A. Distribution Engineer, Tacoma Light Dept., Tacoma, Wash.
MCBRIAN, EDWARD W., Mechanical Engineer, Fox Bros. & Co., New York, N. Y.
MCGRATH, WILLIAM H., Vice-President, Puget Sound Power & Light Co., Seattle, Wash.
MATTHEWS, HOWARD D., Prof. of Elec. Machine Design, School of Engineering of Milwaukee, Milwaukee, Wis.
MULLEN, CLYDE A., Engineer of Tests, The Ohio Service Company, Coshocton, O.
NEWTON, JOHN M., Chief Engineer, The Roland T. Oakes Company, Holyoke, Mass.
O'CONNELL, WILLIAM T., Estimator & Designer, Elec. Div., Panama Canal, Balboa Heights, C. Z.
OSTER, EUGENE, Electrical & Mechanical Director, The Ault & Wiborg Co., Cincinnati, Ohio.
OWENS, JAMES W., Welding Aid & Asst. Shop Supt., U. S. Navy Yard, Norfolk, Va.
PARKER, SAMUEL R., Engineer of Plant, Saskatchewan Government Telephones, Regina, Sask.
RICH, EDWARD P., Consulting Engineer, Chicago, Ill.
ROWE, E. C., Chief Draftsman, Commonwealth Edison Company, Chicago, Ill.
SEARS, GEORGE C., Supt., White River Division, Puget Sound Power & Light Co., Dieringer, Wash.
SHOEMAKER, JOSEPH J., Supt. of Public Utilities, Town of Sibley, Sibley, Ia.
TOLMAN, CLARENCE M., Moose Mountain Ltd., Sellwood, Ont.
TRAVER, O. C., Supervising Designing Engineer, Switchboard Dept., General Electric Co., Schenectady, N. Y.
WEGG, DAVID S., JR., Sales Engineer, Allis-Chalmers Mfg. Co., Chicago, Ill.
WENTWORTH, HERBERT H., Industrial & Railway Motor Engg. Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
WILKINSON, C. T., Engineer & Manager, Milliken Manufacturing Syndicate, London, England.
WILSON, N. P., District Service Manager, Westinghouse Elec. & Mfg. Co., Seattle, Wash.
WOODCOCK, LANCELOT R., Resident Engineer, Riegos y Fuerza del Ebro, Barcelona, Spain.

TRANSFERRED TO GRADE OF FELLOW OCTOBER 8, 1920

GRAHAM, EARL A., General Manager & Chief Engineer, Compania Panamena de Fuerza y Luz, Ancon, Canal Zone.
LUNDY, AYRES D., Member of Firm, Sargent & Lundy, Chicago, Ill.
STEVENS, WILLIAM C., Sales Manager, The Cutler-Hammer Mfg. Co., Milwaukee, Wis.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held September 27, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary

To grade of Fellow

BIRD, WILLIAM L., Manager, Secretary, Director, Kaministiquia Power Co., Fort William, Ont.
BRANDON, EDGAR T. J., Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.
MOREHOUSE, LYMAN F., Equipment Development Engineer, American Telephone & Telegraph Co., New York, N. Y.
WYNNE, FRANCIS E., Manager, Railway Equipment Engineering Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

To grade of Member

BENJAMIN, REUBEN B., President, Benjamin Electric Mfg. Co., Chicago, Ill.
BILLIP, ERNEST H., Partner with J. J. Naugle, New York, N. Y.
BOVEE, BENEDICT A., Professor of Experimental Electrical Engineering, School of Engineering, Milwaukee, Wis.
BRADEN, NORMAN S., Vice-President, Canadian Westinghouse Co. Ltd., Hamilton, Canada
BUCHANAN, EDWARD V., General Manager, Public Utilities Commission, London, Ontario
CARLSON, FREDERICK W., Supt. of Electrical Dept., Davison Chemical Co., Curtis Bay, Md.
ELLIOTT, LOUIS, Steam Plant Engineer, Electric Bond & Share Co., New York, N. Y.
FLANDERS, CHARLES K., Captain, Signal Corps, U. S. A., New York, N. Y.
GIBBS, GEORGE S., Sales Engineer, Representative, Westinghouse Elec. & Mfg. Co., Boston, Mass.
HERTNER, JOHN H., President, Hertner Electric Co., Cleveland, O.
NEILD, JAMES F., Supt. of Substations, Toronto Railway Co., Toronto, Ont.
ROBERTS, EDWARD A., Engineer, John A. Beeler, New York, N. Y.

SCHWARZE, FRED, Electrical Engineer, Pfister & Vogel Leather Co., Milwaukee, Wis.
SHUCK, GORDON R., Instructor in Electrical Engineering, University of Washington, Seattle, Wash.
UPSON, WALTER L., Professor Electrical Engineering, Washington University, St. Louis, Mo.
WOOLHISER, H. L., Business Manager, Village of Winnetka, Winnetka, Ill.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before November 30, 1920.

Adair, Samuel E., New York, N. Y.
Allen, Roy N., (Member), Seattle, Wash.
Ames, Robert P., St. Louis, Mo.
Archiable, George W., Cincinnati, Ohio
Arnold, William E., Southbridge, Mass.
Avery, William Y., (Member), Bayonne, N. J.
Ayliffe, Harold E., St. Louis, Mo.

STUDENTS ENROLLED OCTOBER 8, 1920

11684 Theel, William F., School of Engineering of Milwaukee
11685 Missey, Frank J., School of Engineering of Milwaukee
11686 Evans, Herbert P., School of Engineering of Milwaukee
11687 Petersen, Folmer H., School of Engineering of Milwaukee
11688 Webb, Edmond F., School of Engineering of Milwaukee
11689 Seaman, Ellsworth F., School of Engineering of Milwauke
11690 Ryan, John Price, New York Electrical School
11691 Walker Erwin Vincent, Purdue University
11692 Conger, John A., University of Washington
11693 Ignarra, Otto de Barros, Ohio Northern University
11694 Schlottere, Edmund Lehr, Penn State College
11695 Rauhe, Clinton H., New York Electrical School
11696 Mulvany, Herbert C., University of California
11697 Cates, William K., University of California
11698 Pollinghorn, Frank A., University of California
11699 Travis, Beverly A., University of Washington
11700 Kendall, Ralph M., Maine University
11701 McGee, Walter R., Pennsylvania State College
11702 Harper, Solomon, Syracuse University
11703 McNamara, Francis T., Sheffield Scientific School
11704 Lohmann, Pierce F., Pennsylvania State College
11705 Fitzgerald, Philip J., New York Electrical School

OFFICERS OF A. I. E. E. 1920-1921

President
A. W. Berresford

Junior Past-Presidents

Comfort A. Adams	Calvert Townley

Vice-Presidents

Charles S. Ruffner	C. E. Magnusson
Charles Robbins	E. H. Martindale
L. T. Robinson	C. S. McDowell

Managers

Walter A. Hall	Walter I. Slichter
William A. Del Mar	G. Faccioli
Wilfred Sykes	Frank D. Newbury
L. E. Imlay	Harold B. Smith
F. F. Fowle	James F. Lincoln
L. F. Morehouse	E. B. Craft

Treasurer	**Secretary**
George A. Hamilton	F. L. Hutchinson

A. I. E. E. COMMITTEES

(A complete list of the personnel of Institute committees will be found in the October issue of the Journal and will be published again in the January issue.)

GENERAL STANDING COMMITTEES AND CHAIRMEN

Executive, A. W. Berresford
Finance, Charles Robbins
Meetings and Papers, W. I. Slichter
Publication, N. A. Carle
Coordination of Institute Activities, L. T. Robinson
Board of Examiners, Clayton H. Sharp
Sections, John B. Fisken
Student Branches, C. Francis Harding
Membership, E. H. Martindale
Public Policy, H. W. Buck
Law, H. H. Barnes, Jr.
Headquarters, Wm. A. Del Mar
Safety Codes, Farley Osgood
Code of Principles of Professional Conduct, George F. Sever
U. S. National Committee of I. E. C., C. O. Mailloux
Standards, Dugald C. Jackson
Edison Medal, Comfort A. Adams

SPECIAL COMMITTEES AND CHAIRMEN

Geographical Divisions and Election Procedure, H. H. Barnes, Jr.
Super-Power System, W. S. Murray

TECHNICAL COMMITTEES AND CHAIRMEN

Economics of Electric Service, Philip Torchio
Educational, C. E. Magnusson
Electrical Machinery, B. A. Behrend
Electrochemistry and Electrometallurgy, F. A. J. FitzGerald
Electrophysics, F. W. Peek, Jr.
Industrial and Domestic Power, A. G. Pierce
Instruments and Measurements, F. V. Magalhaes
Iron and Steel Industry, W. F. James
Lighting and Illumination, C. E. Clewell
Marine, Arthur Parker
Mines, Graham Bright,
Power Stations, H. P. Liversidge
Protective Devices, D. W. Roper
Telegraphy and Telephony, Donald McNicol
Traction and Transportation, Charles S. Ruffner
Transmission and Distribution, E. B. Meyer

A. I. E. E. REPRESENTATION

(The Institute is represented on the following bodies; the names of the representatives will be found in the October 1920 issue of the Journal and will be published again in the January issue.)

Council of the American Association for the Advancement of Science
American Bureau of Welding
American Committee on Electrolysis
American Engineering Standards Committee
American Engineering Council of the Federated American Engineering Societies
American Year Book Advisory Board
Board of Trustees, United Engineering Society
Engineering Council
Engineering Foundation Board
Franco-American Engineering Committee
John Fritz Medal Board of Award
Joint Committee on Engineering Education
Joint Committee on Standard Thread for Insulators and Insulator Pins
Library Board of United Engineering Society
Electrical Committee of National Fire Protection Association
National Joint Committee on Overhead and Underground Line Construction
Engineering Division, National Research Council
Naval Consulting Board
Special Joint Committee on Determination of Power Factor in Polyphase Circuits
U. S. National Committee of the International Illumination Commission
Commission of Washington Award

A. I. E. E. SECTIONS AND BRANCHES

A complete list of the 37 Sections and 64 Branches of the Institute, with the names of the chairmen and secretaries, will be found in the October 1920 issue of the Journal and will be published again in the January issue.

JOURNAL

OF THE

American Institute of Electrical Engineers

PUBLISHED MONTHLY BY THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS
33 West 39th Street, New York.

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other Countries. Single copies $1.00.

Entered as matter of the second class at the Post Office, New York, N. Y., May 10, 1905, under the Act of Congress, March 3, 1879.
Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized on August 3, 1918.

Vol. XXXIX DECEMBER, 1920 Number 12

The Epoch-Making Discoveries of the Years 1819 and 1820*

BY ELIHU THOMSON

General Electric Co., Lynn, Mass.

IT is fitting that in Philadelphia we should celebrate the centenary of the great discoveries in electromagnetism. It was here that Franklin's investigations in electricity were made, culminating in the kite experiment. It was here that he and a few confreres founded the American Philosophical Society which became a national institution for the spread of that spirit of science and philosophy characteristic of Franklin. It was here not many years ago that under its auspices a very notable commemoration of the centenary of Franklin's work was held. Not far from here in Princeton the pioneer work of Henry in electromagnetism, induction of currents, and oscillations was done nearly a century ago. Not far to the south from here the first Morse telegraph line was established in 1844. In Philadelphia, Robert Hare in the early years of last century did his work with voltaic batteries. Here Bell first exhibited his speaking telephone at the Centennial Exhibition of 1876, calling such witnesses as Sir William Thomson (Lord Kelvin) to hear it speak. Not far from here, in the Laboratory of Edison in Menlo Park, the incandescent lamp was born in 1879. Here again in commemoration of Franklin was established the Franklin Institute, the influence of which has been so marked a factor in science and the mechanic arts everywhere. Under its auspices the first investigation of the electrical properties of the dynamo was made in 1877, and the first Electrical Exhibition held in America in 1884, the Paris Exposition of 1881 being the only forerunner. It is a pleasure to note at this time the possibility of great and increasing lustre to its future in the electrical field has come by a large bequest from one whom the present speaker knew well in his old Philadelphia days, Mr. Henry Bartol. I am reminded that the first meeting of the American Institute of Electrical Engineers was held at Philadelphia. And now, to speak very briefly of more intimate but infinitely less important matters, may the speaker modestly add that here over fifty-five years ago he built his first electrical machine, voltaic piles, batteries, electromagnets and telegraph, acquiring through them in his early years an insight into the science of electricity as it then existed. It was here that he taught science for ten years in the old Central High School at Broad & Green streets and that during this period in 1875 there was made, incidentally, the first wireless transmission, using induction coil, spark gap, ground and radiating conductor, briefly described in the *Franklin Institute Journal* of the time, and recently related more in detail by Professor M. B. Snyder of the school. It was here in Philadelphia that the speaker did his first electrical engineering, and definitely chose that professional career which has kept him alive and busy ever since.

There are times when an epoch-making discovery gives rise to a new science or art, or opens up entirely new fields for experimental research. When this has occurred before our time we can at best visualize the antecedent conditions imperfectly. The background of such a discovery as was made in 1819 by Hans Christian Oersted of Copenhagen, and announced in July 1820, is scarcely reproducible now. We shall not attempt to do so. Simple as was the experiment of Oersted, the fundamental character of his results was instantly recognized by his contemporary leaders in science, such as Ampere, Arago, Biot, Davy and Faraday who repeated the experiments, and served to stimulate them to an intensity of research work which at once brought wonderful additions to human knowledge.

Oersted, a Dane, born in 1777, was educated at the University of Copenhagen, and in 1806 occupied the chair of Physics there. Though he had already done important work, he was immortalized by his being the first to discover and investigate the effects of a current in a conductor upon a magnetized needle. It was, or at least may now seem to us, a most simple discovery, the outcome of experiments of equal simplicity. Nevertheless, subsequent events soon proved it to be the foundation stone upon which now rests the great science of electromagnetism. Oersted found

*Address delivered at the Philadelphia Meeting of the A. I. E. E., October 8, 1920.

that a wire conveying the current of a voltaic battery, such wire being called by him a "conjunctive wire," affected a freely pivoted magnetic needle in such a manner that the needle tended to set itself at right angles to the wire. The deflection was shown to be definite as to direction, depending on the direction of the current in the wire, the position of the poles of the needle and the relation of positions of the wire and the needle. It was recognized, also, that if the magnet were fixed in position and the conjunctive wire free to move, corresponding movements of the wire would take place. This discovery was given out in a brief work in Latin, the title of which was, in substance, "Experiments Concerning the Effect of Electric Conflict on the Magnetic Needle."

Oersted had apparently convinced himself long before of there being a necessary connection between electricity and magnetism and had held, perhaps more pertinaciously than others, to this view. In recognition of the great scientific value of his discovery the prize of the French Institute was awarded to him. This had already been given to Davy for his electrochemical discoveries, such as that of the separation of the alkali metals, sodium and potassium, from their compounds. Oersted also received the Copley medal of the Royal Society of London, and was honored by the distinction of Knighthood. Dying in 1851 at seventy-four, he had lived to see great progress in electromagnetism and to witness some of its early applications to the needs of mankind, such as the telegraph.

The following translation of Oersted's description appears in Barlow's "Magnetic Attractions," a book published in 1824. After assuming current passing in the conjunctive wire—

Let the straight part of this wire be placed horizontally above the magnetic needle properly suspended and parallel to it. If necessary, the uniting wire is bent so as to assume a proper position for the experiment. Things being in this state the needle will be moved, and the end of it next the negative side of the battery will go westward.

If the distance of the uniting wire does not exceed three-quarters of an inch from the needle the declination of the needle makes an angle of 45 deg. If the distance is increased, the angle diminishes proportionally. The declination likewise varies with the power of the battery.

The uniting wire may change its place, either towards the east or west, provided it continues parallel to the needle, without any other change of the effect than in respect to its quantity. Hence the effect cannot be ascribed to attraction; for the same pole of the magnetic needle which approaches the uniting wire, while placed on its east side, ought to recede from it when placed on the west side, if these declinations depended on attractions and repulsions. The uniting conductor may consist of several wires or metallic ribbons connected together. The nature of the metal does not alter the effect, but merely the quantity. Wires of platinum, gold, silver, brass, iron, ribbons of lead, and tin, a mass of mercury were employed with equal success. The conductor does not lose its effect, though interrupted by water, unless the interruption amounts to several inches in length.

The effect of the uniting wire passes to the needle through glass, metals, wood, resin, stoneware, stones, for it is not taken away by interposing plates of glass, metal or wood. Even glass, metal and wood interposed at once do not destroy, and indeed scarcely diminish the effect. The disk of the electrophorus, plates of porphyry, a stoneware vessel even filled with water were interposed with the same result. We found the effects unchanged when the needle was included in a brass box filled with water. It is needless to observe that the transmission of effects through all these matters has never before been observed in electricity and galvanism. If the uniting wire be placed under the magnetic needle, all the effects are the same as when it is above the needle, only they are in opposite directions; for the pole of the magnetic needle next to the battery declines to the east.

That these facts may be more easily retained, we may use this formula: the pole above which the negative electricity enters is turned to the west; under which to the east.

If the uniting wire be so turned in a horizontal plane as to form a gradually increasing angle with the magnetic meridian, the declination of the needle increases, if the motion of the wire be toward the place of the disturbed needle; but it diminishes if the wire moves further from that place.

When the uniting wire is situated in the same horizontal plane in which the needle moves, and parallel to it, no declination is produced either to the east or to the west; but an inclination takes place, so that the pole next which the negative electricity enters the wire is depressed when the wire is situated on the west side, and elevated when situated on the east side.

If the uniting wire be placed perpendicularly to the plane of the magnetic meridian, whether above or below it, the needle remains at rest, unless it be very near the pole; in that case the pole is elevated when the entrance is from the west side of the wire and depressed when from the east side.

When the uniting wire is placed perpendicularly opposite to the pole of the magnetic needle and the upper extremity of the wire receives the negative electricity, the pole is moved toward the east; but when the wire is opposite to a point between the pole and the middle of the needle the pole is moved towards the west. When the upper end of the wire receives positive electricity, the phenomena are reversed.

If the uniting wire be bent so as to form two legs parallel to each other, it repels or attracts the magnetic poles according to the different conditions of the case. Suppose the wire placed opposite to either pole of the needle, so that the plane of the parallel legs is perpendicular to the magnetic meridian, and let the eastern leg be united with the negative end, the western leg with the positive end of the battery, and in that case the nearest pole will be repelled either to the east or west, according to the position of the plane of the leg. The eastmost leg being united with the positive and westwards with the negative side of the battery, the nearest pole will be attracted. When the plane of the legs is placed perpendicular to the place between the pole and the middle of the needle, the same effects occur, but reversed.

A brass needle suspended like a magnetic needle, is not moved by the effect of the uniting wire. Needles of glass and of gumlac remain likewise quiescent.

On first thought it may seem singular that as many as twenty years elapsed after the Galvani and Volta discoveries, before such a simple experiment as that of Oersted was tried. The only hint or suggestion of prior observation appears in the statement that about 1802 Romagnasi of Trent (a town in the Austrian Tyrol) had noticed an effect on a compass needle in the neighborhood of a voltaic pile. Evidently, however the observation if made was very imperfect, as it led to no consistent recorded result. In this connection we must consider that the early years of the last century were disturbed by wars stirring the whole of Europe, and

further that the available voltaic currents must then have been relatively weak owing to the small area of battery plates used and to a high resistance of electrolyte. Strong acid could not be availed of as the zinc elements were not amalgamated, a procedure which was later almost universal. Again, the negative element was usually copper, giving against zinc a low voltage and subject to rapid polarization. There was, therefore, in the years before Oersted, little probability of such large currents being available or usual as would be needed when a single wire was used for the deflecting agency. This was, of course, before the principle of coiling the conductor to increase its effect was known. Dr. Robert Hare, the inventor of the oxyhydrogen or compound blowpipe, first appreciated, apparently in 1816, the need of increasing the surface of the zinc and copper to obtain, as it was afterward called, "large quantity." The blowpipe in his hands had become the most convenient source of heat of high temperature known to man, and the known heating effects of electric currents naturally led Hare to investigate means of intensifying them. He produced two forms of apparatus which were known as the Hare Calorimotor and the Hare Deflagrator. In the prior "trough" battery the plates were small, rarely more than four inches square, with one side only active. Hare rolled his zinc and copper sheets into interlaced spirals, spaced apart by wooden separators, so that not only large plates could be used, but both sides of the plates were active. Another form giving a similar result was embodied in the "deflagrator" which was used to deflagrate strips of thin metal in the same manner as the blowing of a modern safety fuse. In early youth it was the privilege of the writer to see examples of the apparatus of Hare which were preserved at the University of Pennsylvania then located in Philadelphia on the west side of Tenth St., between Chestnut and Market streets. Hare had been Professor of Chemistry there during the early years of the past century. The Hare apparatus is mentioned here because of a passage occurring in a work on Heat and Electricity printed in 1830. Its author, Thomas Thomson, M. D., was very eminent in the science of his time. The passage reads as follows: "The apparatus employed by Oersted, and of the efficacy of which he speaks in high terms, approached very nearly to this last one of Hare." This passage occurs just following a description of the "deflagrator". The statement seems to imply that Oersted early appreciated the value in a voltaic battery of large active surface, or as we should now say "low internal resistance." May it not be that this condition was the secret of his experimental success? Even in Franklin's time it had been observed that electric discharges had some obscure action on the magnetic needle, for sometimes compasses were demagnetized wholly or in part, or even reversed, when in proximity to a lightning stroke. Beccaria, the Italian contemporary of Franklin, tried many experiments with magnetized needles and heavy Leyden jar condenser discharges sent through them, but did not succeed in establishing any magnetic effect as due to the discharges. Such effects as he did obtain are readily interpretable at this time as the natural result of a vigorous shaking up, mechanical, or thermal, while the needle was in a magnetic field, such for example as that of the earth. Subsequently to Oersted's discovery, however, condenser discharges sent through a helix or spiral surrounding the needle were found to produce decided magnetic effects thereon.

The news of Oersted's discovery reached Paris, as it appears, through Arago, who had witnessed the experiments in Geneva on September 11, 1820, and on September 18th Andre Marie Ampère presented a paper to the Paris Academy of Sciences, remarkable for its originality and for the variety and accuracy of the experimental results recorded. In it he dealt with the interactions and repulsions of wires conveying currents and the magnetic effects of helices of wire, showing these latter to be possessed of magnetic poles. The fact that Ampère's paper appeared only a week after Oersted's discovery had become known to him, gives to it a unique place in the history of science. It was the production of a mind of the first order working at high pressure. Ampère was born at Lyons in 1775. As a child his precocity was most unusual. His tendency was toward mathematics, though his reading during youth brought to him a wide range of information in many branches of knowledge. The death of his father on the scaffold as a victim of political conditions almost wrecked his young life. Owing later to fortunate environment at a critical time, he gradually recovered, and in 1809, at thirty-four, was made Professor of Analysis at the Paris Polytechnic. The Oersted announcement evidently stirred him deeply and he went immediately to work with wonderful zeal and sagacity, to unravel the mysterious relationship between magnetism and currents, suggested only in part by Oersted's experiment. In his hands the fundamental character of these relationships became plain, and their future possibilities clear. It is recorded that he even suggested at the time the plan of a telegraph of simple form. As a side light, it appears that Ampère's discovery of the fact that parallel currents in the same direction in wires cause attraction, and when in the opposite direction repulsion, seems to have puzzled some of the philosophers of the time, for it was known of course that similar electricities repel and dissimilar attract. Why should not, therefore, similar currents repel and unlike attract, when in fact the exact opposite was the case? Ingenious, though altogether fallacious was an explanation first put forward and credited to Oersted. He was apparently driven to imagining that the current in wires did not go straight along the axis, but was conducted in a helical course in them always the same for the same direction of current. This was a pure invention without facts

to support it. But upon it he founded a theory of attraction and repulsion of parallel wires involving the old time attraction of unlike and repulsion of like electricities. In reality this theory bore with it its own refutation, as a few test experiments might easily have shown. In fact Barlow in England pointed out some of the contradictions involved in these ideas which had been elaborated by Ampère. In relation to this fanciful theory I find in the old book, before referred to as published in 1830, the following naive allusion—"This way of accounting for the phenomena of electromagnetism was first employed by Oersted. It was afterward used by others, particularly by Dr. Wollaston and M. Ampère with much felicity." The present writer does not vouch for the correctness of these statements. As soon, however, as the effects of currents in establishing magnetic circuits around them was worked out, the true cause of the attractions and repulsions of parallel wires became clear, and the fanciful notion of spiral courses for currents inside a conductor was abandoned. Such a notion has of course no relation to the later theory of Ampère for accounting for magnetism in iron or permanent magnets, in which he assumes each magnetic element to consist of a closed circuit with a current always circulating therein, a theory which to this day has not been displaced, but rather refined and strengthened by its further extension by Ewing and by the electron theory. It was in fact Ampère who referred all magnetism to electricity or electric currents, now interpreted as movement of electrons. The need of Ampère's clarification is perhaps made more evident from the following quotation, if it be a fact, "Oersted originally believed that the negative electricity propelled the north pole of the magnet, but had no effect on the south: while positive electricity propelled the south and had no effect on the north pole." The writer has not verified this statement as expressing the original ideas of Oersted, but if they at any time represented his view they must soon have been dispelled. They would be, perhaps, a sort of survival of older notions, at least in part, since before the "conjunctive wire" was used fruitless efforts had been made to connect magnetism and electricity while using batteries on open circuit. Ampère formulated a simple rule known as Ampère's rule, for determining the direction of deflection of a magnet or the direction of development of magnetism by a wire conveying current. It may be stated (bearing in mind that the direction of current, we assume, positive to negative, is merely a convention) about as follows: Conceive oneself lying or swimming in the current in such a way that the current enters by the feet and leaves by the head as we face the needle. Then the action will be that the north pole of the needle will turn to one's left. The writer must confess that when he first learned this rule it seemed rather clumsy to him, perhaps more so because he was sometimes treated to the ludicrous spectacle of an obese professor trying to twist himself with respect to an immovable wire circuit into curious attitudes so as to lie or swim in the current, and so note the direction of magnetism produced. Other ways of remembering the relation given by Ampère's rule have been devised, but perhaps none excel in ease and simplicity of application, a simple gesture of the hand, which has been used by the writer for about fifty years. The hand is held out with the index finger pointed away. If the hand be now given a swing or turn in righthanded direction, still keeping the forefinger directed as at first, such swing, turn, or rotation representing direction of current in a circuit, the north magnetic pole will be directed away as the forefinger points. Reversing the gesture, turning or swinging the hand counterclockwise makes the north pole take direction toward the wrist or forearm, or what is the same thing the extended forefinger represents the direction of south polarity. As the swing or slight rotation given the hand from the wrist and elbow represents all directions of current, above, below, and to the right or left of the magnetic axis considered, it is easy to select any element of current course matching actual conditions. Moreover, the same gesture (for it is simply a gesture, not a rule) applies equally to the relations of magnetic field developed around the course of a current, for if current passes in a wire in the direction of the point of the index finger, the magnetic circuit around it will have north polarity directed righthandedly, and lefthandedly or counterclockwise if the current has opposite direction; as from the tip of the index finger inward toward the wrist. In any case it is only necessary to make the simple gesture, which requires no especial mental effort. This soon becomes a matter of habit; a mistake being practically impossible.

According to de la Rive, Traite d'Electricite, Vol. 1, it was Arago who was first to show that a wire of copper or other metal acquired, when traversed by a strong current, the property of attracting and retaining around it, under the form of a cylindrical envelope, a quantity of iron filings; the filings falling off immediately when the current ceased to flow, and being reattracted on the restoration of the current. This experiment, prior to all those of Ampère, is the first which established in a striking manner that electric current impressed on conductors when it is transmitted by them, properties fully analogous to those of magnets, and not alone to magnetic bodies; in other terms, that it magnetizes them and does not simply render them susceptible of being magnetized. In fact, the iron filings are magnetized by the current as they would be by a magnet, and are in consequence attracted by the wire which transmits the current. This foregoing statement is substantially that of the account given by de la Rive, translated. Ampère and Davy are also credited with having made the

same observation, but if de la Rive is right, it was first made by Arago. But the statement is wrong; the wire is not made a magnet in the usual sense; the filings merely effect a better closure of the magnetic field lines around the wire than air does.

In this filings experiment was the first striking exemplification of the phenomenon of temporary magnetism in iron, so fundamental to the unlimited variety of electromagnets and mechanisms founded thereon; the basic principle of the Morse telegraph and most other signaling or electric recording systems and essential to the greater machinery of electrical engineering, developed for the most part in the latter half of the past century. Davy is credited with furnishing the proof that steel could be magnetized even at a considerable distance from the battery wire.

Arago went further and made his conducting wire into a spiral, and then succeeded in magnetizing steel needles placed in the axis thereof. In his pioneer experiments the spiral was wound open around a glass tube as a support, the wire itself being presumably bare. In Sillimans' Principle of Physics, (a well-known and much used text-book from its first edition in 1858, for perhaps thirty years thereafter) in describing the above experiment, there is the following statement: "If the helix is wound on a tube of glass, paper or wood, these substances offer no resistance to the passage of the power; but if a tube of copper or other metal were employed, the magnetizing power of the current on the enclosed bar would be destroyed." Such a statement means either that the metal tube short-circuited the bare wire of the helix or that currents of extremely brief duration, such as condenser discharges are concerned, or it is wrong as a statement of fact. It was indeed soon found that even "if common electricity be made to pass along the spiral conducting wire, the needle is equally converted into a magnet." Common electricity was evidently the frictional or static electricity thus distinguished from the then newer or less common voltaic current, later called dynamic electricity. The principle of coiling or increasing the turns on the original rectangular circuits of Oersted and Ampere was soon appreciated; even for deflection of needles. A hank of insulated wire wound around the hand or upon a rectangular block of wood as a mould and tied by string to preserve its form, was used to surround the needle; such a coil being the prototype of the taped coil of today. It seems to have taken some time to develop the coil consisting of a spool or bobbin wound closely with insulated wire. Schweigger used the rectangular coil of many turns in his "electric multiplier"; the term "multiplier" being extant for at least fifty years as applied to galvanometers with such coils.

The floating battery of de la Rive with either its "conjunctive wire", or with a spiral connecting the poles, was an exceedingly neat arrangement for showing the mutual action of currents and magnets, or the effects of wires conveying currents on others more or less parallel thereto. It seems to have been a very early modification of Oersted's and Ampere's apparatus. It avoided the problem of pivots conveying current, such as by mercury cups surrounding them. Ampere had considered a spiral conveying current as an actual magnet or as very similar thereto. It was soon found that iron or steel bars were drawn into the axis of spirals—the solenoid of today—and it is curious to note that Faraday disputed Ampere's conclusion by showing that a hollow magnet would only attract a needle by its outer surface and edges.

Arago's famous disk experiment, involving the discovery that a moving conducting disk of non-magnetic metal such as copper possessed an effect in the nature of a drag on a poised magnetic needle near it, was made about 1824. It was found also that if the needle was spun around over a conducting disk or plate, it was rapidly slowed or damped. These experiments were carried on by using a great variety of materials for the disk and wide variations in the magnitude of the effects were observed. Precautions were taken to eliminate any effects due to air currents. It was found that disks of the best conducting metal such as copper were the most effective. Here we have, then the prototype of eddy current dampers in magnetic fields. Curious hypotheses were advanced to account for the effects, such as the assumption of special forms of magnetism generated by revolution. In reality, had the secret of the action of the Arago disk been found, the generation of currents in a conductor moving in a magnetic field would have been discovered, and Faraday's discovery of that great principle in 1831 would have been anticipated by a number of years.

The full name of Arago was Francois Jean Dominique Arago, and he was a scientist of varied activities.

There is no space here to refer to his career except in the briefest possible way. Born in 1786 at Estagel near Perpignan, France, he displayed in his early years great aptitude for learning, and at eighteen became secretary to the Observatory of Paris, which brought him into contact with the famous La Place, and he was collaborator with Biot. He served in the determination of the meter as the unit of length; in measuring the ten-millionth of a quadrant of the earth's meridian. This task, involving travel into lands of turmoil, brought great dangers, imprisonment, escape in disguise, capture by the Spanish and prison again. Even after release he remained a long time in quarantine, on account of disease conditions. Given the post of astronomer in the Royal Observatory in Paris by Napoleon, in 1816, he started the famous Journal *Annales de Physique et de Chimie*. As Secretary of the Paris Academy of Science, Chief Director of the Observatory and as Member of the Chamber of Deputies, his life was a very full one, and its responsibilities heavy. He was associated with Fresnel in giving form to the undulatory theory of light proposing to test the theory by studying retardation in refractive media.

In fact his work on polarization of light, invention of the polariscope, and other researches rank scarcely less highly than his work in electromagnetism, with which we are here chiefly concerned.

The later discoveries by Faraday and his brilliant researches on electromagnetic rotations, and especially his discovery in 1831 of induction of currents by magnetism refined the early theories and added greatly to the development of electromagnetic science. Somewhat crude as the earlier ideas were, the clarification given them by Faraday, Maxwell, Kelvin and many others had the most profound effect on its future. As a direct outcome of Oersted's observations, mention may be made of the discovery in 1823 by Seebeck of thermoelectric currents in a closed circuit. He used a rectangle in a vertical plane surrounding a pivoted magnetic needle. The base of this closed circuit, so arranged, was a bar of antimony, while the ends and upper side were of copper. By heating one of the junctions of the antimony bar with the copper, deflection of the needle showed the presence of a current in the closed loop around the needle. This was followed by examination of the effects of junctions of different metals and conductors heated to various temperatures and led to the well-known table of thermoelectric powers. The thermo pile of Melloni, so delicate as a heat detector, was an outcome, and was used by him in his beautiful researches in diathermancy.

Having in the foregoing traced briefly the work of the pioneers in laying the foundation of the science a century ago, it is perhaps unnecessary to remind electricians and engineers of the great scientific advances and the important applications which soon followed. Some of them became familiar studies of the electrical student fifty years ago. This progress has continued and apparently at an increasing rate ever since.

To the consciousness of the writer the period of a hundred years seems continually to dwindle. He is reminded of the fact that his own life's span has covered more than two-thirds of a century. Looked at in this way, the Oersted, Ampere and Arago experiments do not seem to have been made, after all, so very long ago. Outside of forms of electromagnetic telegraph, the years following 1820 saw but few other applications of importance; but there were many examples of electromagnetic apparatus used for instruction in schools. The little book, now rare, entitled "Davis' Manual of Magnetism" was and is interesting as a catalogue, with brief descriptions, of such apparatus, some of which is doubtless still extant in the older collections. The first edition was publised in Boston in 1842, and the author, Daniel Davis, Jr., called himself "Magnetical Instrument Maker."

It may be interesting to quote the preface of this pioneer book as follows:

"Magnetism and electricity have become related sciences within so short a period, and their growth has been so rapid, that many important facts which have been observed have not yet been collected in any scientific treatise and the amount of unwritten knowledge has been constantly increasing. . . . . It will be found that many of the observations recorded here and many of the instruments described are new."

This statement was true enough, and for that reason, though it is a primitive production, the book has become almost a classic.

How many, or rather how few of us are left of those who as boys experimented with the sulphate of copper battery as their source of current, with flat spirals such as Henry employed, or with such apparatus as Oersted, Ampere and Arago used. We find in this little book of Davis' Henry's electromagnet, de la Rives floating battery, Faraday's revolving circuits and magnets, Barlow's spur wheel, Page's revolving ring, his revolving magnet and revolving multiplier, and other examples of the simplest type of electric motors with commutator and brushes called "pole changers," and even apparatus with both commutator, revolving brushes, and slip rings, so that both elements of the motor might revolve oppositely. There were bell engines, so-called, and reciprocating engines, elementary motors driven by thermoelectric currents, or by batteries revolving, all involving the simple principles of interaction of circuits and magnets, permanent or temporary. These and other simple forms of apparatus, besides the older devices for "static" electricity, were the things electrical with which the youngster with an electrical bent became familiar, either in his reading, or better, by the fascination of experiment with them. Such equipment characterized the infant years of the science; now grown to a giant with no limit to future growth.

It was natural that the first great practical application of electromagnetic principles should be found in the telegraph.

Attempts have been made as early as 1774 to telegraph by the electricity of frictional machines, which even as late as 1850 was called "machine electricity" or "common electricity from machines." Even in 1816 Ronalds in England was attempting to signal through long circuits by Leyden jar discharges. After the discovery of the voltaic pile in 1800 there was a better prospect of success, and Sömmering in 1808 proposed a system of 35 wires at the ends of which were gold strips in water, upon which strips gas appeared on the passage of current, which appearance constituted the signal received. There was a wire so arranged for each letter or character transmitted. It was Ampere, who, just after Oersted's discovery, proposed to substitute in Sömmering's system deflected needles for the voltmeter receivers. Then followed Schilling in Russia in 1832; Gauss and Weber at Gottingen in 1833, and finally Cooke and Wheatstone in England and Steinheil in Munich in 1837, to whom perhaps more than to any others the development of the needle telegraph for practical work was really due.

The Morse type of telegraph was early distinguished as the electromagnetic telegraph, or one based on the use of electromagnets. Barlow in England seems to

have made an early suggestion of the kind, but it was not until 1830, upon the construction of the first powerful electromagnets by Joseph Henry of Princeton, New Jersey, that such a form became possible. In his first paper on the results of his experiments, Henry proposes to apply them to the telegraph. Samuel F. B. Morse conceived of such a telegraph in 1832, and with the assistance of Vail worked it out practically; and publicly exhibited the Morse system working over a circuit of a third of a mile in 1837, but after that it was nearly seven long years before Congress for consideration, when at last a modest grant was made to establish the famous Baltimore-Washington line first put into operation in 1844.

In the subsequent numerous developments of systems of signaling from the simple call bell to the fire alarm and printing telegraph, the electromagnet holds undisputed sway. In annunciators of many types it is found, as often with polarized cores in relays and in telephone receivers and the like; indispensable in wireless transmission as in transmission by wires. The extreme sensibility of the telephone receiver, coupled with the wonderful delicacy of the ear, makes it most effective for the detection of minute electrical disturbances. With modern themionic amplifiers the possible extension in range of telephonic transmission by wireless waves seems to be without limit.

It is not necessary here to allude to the great developments in the field of electricity and electromagnetism as exemplified in generation and transmission of electrical energy. They have covered the past half century, but the foundation principles belong to those early years of upward of a century ago. Do we cause movement of iron masses by a current coil? It is the experiment of Oersted. Do we cause movement of coils, one with relation to another, as in our motors? It is the experiment of Ampère. Do we generate currents in a conducting mass in a magnetic field? It is the experiment of the Arago disk. When we measure current or energy by galvanometer, voltmeter, electrodynamometer, or wattmeter we have the work of Oersted, Ampère, Arago and Davy illustrated. But these early discoveries had a deeper significance still. They showed that electric currents and magnetism are inseparable—inseparable in practise, inseparable in theory. Moving charges are, as shown by Rowland, the equivalent of currents; and now we are assured that moving charges and currents are moving electrons. Hence moving electrons are magnetic. Like charges or electrons repel each other, but like charges moving in the same general direction attract, for they are the equivalent of parallel currents in the same direction. They repel one another electrostatically and attract one another magnetically. Conversely, oppositely moving charges or electrons should repel, and also continue to repel electrostatically. We are now certainly down to the fundamentals. No vacuum, however perfect, lessens or stops the development of the electric field in it, nor prevents the existence of the magnetic field. Space itself is electromagnetic, using the term in its broadest sense. Like electrons moving in the same direction in such space must attract one another and at some speed the static repulsion of the like charges will be balanced by this attraction. The higher the speed, the closer is the approach, until the repulsion balances the attraction. And just here is the key to the phenomenon of nature. Space, whether empty or full of ether, is fundamentally electromagnetic and perhaps only that. Energy and mass, interchangeable terms and due to relative movements of electrons are electromagnetic and only that. Matter in all its forms, systems of electrons in motion, is an electromagnetic organism. Alive or dead it is electromagnetic and nothing else. All properties of matter, all forms of energy are electromagnetic and electrostatic. If ether exists it is purely and solely electric and magnetic, without mechanical properties, for such properties depend on motion of electrons. Ether as a medium, then, not being mechanical, can neither be in rest nor in motion; it can only be the theatre of electrostatic and magnetic conditions, whatever that may be. The term "space" is as good a one as "ether." These statements may be very sweeping, but do not the recent notions of relativity of Einstein carry us even farther? Space is empty, but has a warp in it; it is curved and of four dimensions, one being time, in which the gravitational field of the sun, or for that matter even the smallest speck of matter or energy is largely a local warping. Are electric and magnetic fields but other kinds of warping in this space, which though empty is full of electric, magnetic, and gravitational fields? Whatever all this may mean, we must remember that scientific theories can never change the facts; they are not creeds, they are means of pointing the way to further additions to our knowledge—to be modified, changed or abandoned according to their usefulness in leading to further knowledge or discovery. The facts of science are its bed-rock foundation, unchanged and unchanging. The discovery, then, of the relation between electricity and magnetism was in reality the discovery of a fundamental fact or principle lying at the foundation of the universe itself; the soul of energy, as also of matter, of electric waves from zero periodicity up to the most penetrating rays of the radium emanations. It is eminently fitting, then, that we celebrate the hundredth anniversary of discoveries, the fruits of which have been of stupendous influence and value, and at the same time carry us to the very foundations of existence; but we meet also to do honor to the great men who first brought those discoveries to light.

The coming century will doubtless have its wonders to unfold, but it is fairly safe to predict that they can hardly exceed in fundamental bearing those revealed to us in the past hundred years.

Oersted's and Ampère's Discoveries

BY M. I. PUPIN

Professor of Electro-Mechanics, Columbia University.

THE names of Oersted and Ampère always recall to my mind the names of several other great men of science who with Oersted and Ampère form a group of intellectual giants. Their pioneer discoveries produced the science of physics and engineering of today. The names of the members of this immortal group are: Copernicus, Kepler, Galileo, Newton, Oersted, Ampère, Faraday and Maxwell. Their discoveries follow each other in evolutionary sequence during an interval of over four centuries, and each one of these discoveries is a link in the chain of evolution of our physical concepts concerning the most fundamental physical phenomena, the phenomena of motion of matter and of electricity. I trust, therefore, that I will be pardoned when on this occasion, the Centennial Celebration of Oersted's and Ampère's discoveries, I indulge in a brief review of the discoveries of the other great scientists who with Oersted and Ampère share in the glory of creating the modern science of dynamics, including electrodynamics.

Prior to Copernicus the science of statics flourished. The interest of the inquiring mind was centered in the study of the conditions of equilibrium, the conditions of rest. The philosophy of Ptolomeus taught man that the earth was at rest and that the universe revolved around it. But a few years after Columbus announced his discovery of a new continent, Copernicus, a great Slavonic astronomer, announced his discovery of a new universe, the universe, namely, in which the planets revolve in circles around the sun, the central body. The earth was no longer a body at rest, a sort of sleepy hollow in the center of a busy universe; it became a most active celestial body, rotating about a fixed axis and moving with enormous velocities in its great orbit around the sun. This great revelation gave a powerful impulse to the inquiring mind of man to turn its attention to the science of motion. A hundred years later, at the time when the Pilgrim fathers landed at Plymouth Rock, Kepler, a great Austrian astronomer, amended the teachings of Copernicus by constructing from Tyho Brahe's astronomical observations his three laws of planetary motions. The Copernican system no longer appeared then as a mere geometrical scheme to describe approximately celestial motions, but it forced the suggestion upon the human mind that there must be a dynamical background to the planetary motions, and, of course, to all motions of matter. Kepler and his contemporaries, although aware of the existence of this dynamical background, could not answer the questions, why the planets move around the sun in elliptical orbits, the sun occupying one of the foci of these orbits? Why the radius vector from a planet to the sun sweeps over equal areas in equal times? And, finally, why the squares of the planetary periods of revolution around the sun are in the same ratio to each other as the cubes of their mean distances from the sun? Galileo, a contemporary of Kepler, was the first to recognize that an answer to these questions cannot be given until we find a correct answer to the older question, the question, namely, why bodies fall to the earth. "Horror vacui" was given as the cause by the scholastics of the Middle Ages. That explanation was just as trivial to Galileo as Aristotle's statement, that bodies fall to the earth because they seek their proper place. Galileo had perfected the telescope and by its aid he discovered the satellites of Jupiter. One cannot help thinking that the orbital motions of these satellites as they appeared to Galileo must have reminded him of the oscillations of Benvennto Cellini's beautiful bronze lamp in the Cathedral of Pisa, which he observed when still a mere youth, and that these periodic motions are closely connected to the motions of a falling body. His experiments with bodies falling from the leaning tower of Pisa shed light upon these problems which stirred Galileo's imagination and they began to clear up the mystery which prevented man from seeing the simple relation which exists between force and the motion produced by it. We may say that Galileo was the first to detect by these experiments at Pisa the existence of a new quantity, namely the momentum of moving mass and the law that the time rate of variation of this momentum is equal to the moving force. No mortal man ever began to clear up a deeper mystery and Lagrange is right when he says that none of Galileo's wonderful discoveries in astronomy displayed Galileo's genius so strikingly as his discovery of the remarkably simple law of motion of a falling body. The world was ready then to catch a glimpse of the true meaning of the dynamical background of Kepler's laws of planetary motion, but nevertheless it took a century before Newton raised upon the foundation prepared by Kepler and Galileo the complete structure of dynamics of moving matter and illustrated its great power by employing it in his demonstration of the existence of universal gravitation and of the law of action of gravitational forces.

This, broadly stated, is the evolutionary development of our knowledge of matter in motion. A strikingly similar evolutionary development took place in our knowledge of electricity in motion. What Copernicus, Kepler, Galileo, and Newton achieved for our

*Address delivered at the Philadelphia Meeting of the A. I. E. E., October 8, 1920.

knowledge of matter in motion, that was achieved by Oersted, Ampère, Faraday and Maxwell for our knowledge of electricity in motion. Oersted is the Copernicus, Ampère is the Kepler, Faraday is the Galileo, and Maxwell is the Newton of the science of electrodynamics, the science of electricity in motion.

This science dates from the beginning of the eighteenth century, when Stephen Gray, a contemporary of Newton, discovered that certain bodies conducted the electrical virtue, as he sometimes called the electrical charge. If conductors did not exist the science of electrical engineering would not exist today, and the science of electricity would probably be in the same state today in which it was prior to the time of Gray. Gray's discovery is, therefore, one of the foundation stones of the science, and it was the first stimulus which excited man's interest in the phenomena of motion of electricity. That interest was very much amplified when Franklin showed that lightning was an electrical discharge, similar to the discharge of a Leyden jar or a Franklin plate. When, finally, at the end of the eighteenth century Galvani and Volta showed how to make a generator of electrical motions which far surpassed both in power and simplicity of construction anything which had been done before, then the science of electrical motion began to develop by leaps and bounds.

The science of the electrical current enters the nineteenth century with Sir Humphry Davy's brilliant experiments with the electrical arc, the melting and the electrolytic power of the electrical current. Sir Humphry Davy did not discover the electrical arc, nor electrolysis, nor the heating power of the electrical current, but his experiments were so surpassingly striking that they gave a new and most powerful impulse to the inquiring mind to search for new physical effects in connection with these wonders produced by electricity in motion.

Oersted was in close touch with Davy's experiments and probably learned from them how to make powerful voltaic generators. The legend exists that Oersted discovered by accident the magnetic force exerted by electricity in motion. Even if the legend were true it would not diminish by one iota Oersted's glory, because history shows that he was in closest touch with the most recent advances of the science; it is there that wonderful accidents always occur to wonderful men. The existence of this legend is undoubtedly due to the fact that no electrical phenomena known to the physicist prior to Oersted's discovery in 1820 would lead one to expect that electricity in motion was capable of producing the magnetic force disovered by Oersted. Heating and electrolysis were local effects produced by moving electricity; they occurred there where the motion actually took place. But the magnetic force discovered by Oersted was not local; it was felt everywhere, in places where no electrical motion of any kind was observable. Ampère's wonderful analysis showed that the circuit carrying an electrical current was a magnet; and it culminated in his great law which determines the magnetic field in terms of the distribution of the electrical currents producing that field. Ampère's contribution to Oersted's discovery is similar to the contribution which the Copernican discovery received when Kepler first announced his three laws of planetary motions; but whereas a century elapsed between Copernicus and Kepler only a week elapsed between the time when Ampère first learned of Oersted's discovery, and Ampère's announcement of his fundamental law of electromagnetism.

Copernicus and Kepler sowed the seed, the fruition of which took place in the brains of Galileo and Newton; that was the great glory of Copernicus and Kepler. Similarly, Oersted and Ampère sowed the seed, the fruition of which took place in the great brains of Faraday and Maxwell, and just as Copernicus and Kepler had prepared the foundation upon which Galileo and Newton raised the structure of the science of dynamics of matter in motion, so Oersted and Ampère prepared the foundation upon which Faraday and Maxwell raised the structure of the science of dynamics of electricity in motion. The evolution of scientific concepts which carries us from Copernicus and Kepler to Galileo and Newton is the same as the evolution of scientific concepts which carries us from Oersted and Ampère to Faraday and Maxwell.

It was first pointed out by Helmholtz and Thomson that the principle of conservation of energy properly understood and applied to the discoveries of Oersted and Ampère leads directly to the inference that variable magnetic fields should produce electrical forces; in other words, the existence of electrical fields produced by varying magnetic fields might have been predicted by pure reasoning even without Faraday's classical experimental researches and discoveries. But in my opinion, it is most fortunate that the principle of energy was not understood at the time of Oersted and Ampère, and that the world needed a Faraday to discover what some other man, much smaller than Faraday, might have predicted from Oersted's and Ampère's discoveries by means of the energy principle.

It was Arago who brought Faraday into the field of research which Oersted and Ampère had just created. The science of electrodynamics owes a great debt to Arago, not only because he was the first to bring to Ampère the first accurate account of Oersted's discovery, but also because soon after that memorable date he discovered a great puzzle for the physicists of the world, the puzzle, namely, of explaining why the oscillations of a magnetic needle are damped out by a conductor in its vicinity, and why a conductor rotating in the vicinity of a magnetic needle will drag the needle with it? That explanation was destined to inaugurate a new movement in the evolution of ideas concerning electrical motions similar to the evolutionary development of scientific ideas inaugurated by Galileo's experiments at Pisa. It was first given by Faraday when in 1831

he discovered electromagnetic induction. Maxwell was born in the same year in which this great discovery was made, the first in the long series of Faraday's fundamental discoveries. Thirty-four years later he interpreted the full meaning of Faraday's discoveries in a manner which reminds one of Newton's interpretation of Galileo's experiments at Pisa.

Continental physicists did not understand the new mode of expression of Faraday, the son of a blacksmith who started his scientific career as an humble assistant in the chemical laboratory of Sir Humphry Davy. He was a man without academic training and without a knowledge of the mathematical language which was then employed by the foremost continental physicists. His experimental discoveries won the unbounded admiration of the world, just as Galileo's astronomical discoveries did, but Faraday as a prophet who had a great scientific message to deliver to the physicists was not understood nor appreciated. Neither was Galileo. Faraday's disciple and apostle, immortal Maxwell, was more successful, but even his contemporaries were not certain that they quite understood his full meaning. Voltaire says that forty years after the publication of Newton's Principia there were no more than twenty men outside of England who followed him.

What, then, was the new message which Faraday and Maxwell delivered to electrical science of their time?

Faraday's discovery of electromagnetic induction made it clear to Faraday himself that the magnetic field discovered by Oersted and analyzed by Ampère represents a state controlled by the electrical motions which produced it, and that the variation of that state in any part of space gives rise to the electrical forces which react against that variation. Faraday called that state the electrotonic state, but he considered it as a mere suggestion because he never succeeded to define it quantitatively and to connect it in a definite manner to induced electrical forces. But in 1855 a mere lad of 24, Clerk Maxwell, who had just been graduated from the University of Cambridge announced that Faraday's electrotonic state is nothing else than the electromagnetic momentum of the magnetic field. The momentum of a moving body is its life and Galileo was the first to detect its existence. Similarly the momentum of moving electricity is its life and Faraday was the first to detect its existence. But there is, as you know, a fundamental difference between Galileo's momentum and Faraday's momentum. The first is localized in the moving material body, the second is not localized in the moving electricity, but is distributed over the whole space wherever the magnetic force of the electrical current is felt. This space distribution of the electromagnetic momentum fascinated the lively imagination of young Maxwell to such an extent that he spent many magnificent efforts in order to explain it by mechanical models. The value of these models is historical; they do not enter into Maxwell's final ormulation of the fundamental laws of electrodynamics which may be stated as follows:

Draw a closed curve, a circuit, in any part of space and consider the magnetic flux which is interlinked with that circuit. The electromagnetic momentum of the magnetic field with respect to that circuit is equal to these flux interlinkages, and its time rate of variation is equal to the electromotive reaction of the circuit, the reaction opposing this change of the electromagnetic momentum. This is one of the fundamental laws of Faraday-Maxwell's electrodynamics. When stated in the above form its formal resemblance to Newton's second law of motion is most striking.

The second law of Maxwell's electrodynamics is a bold extension of Ampère's law of electromagnetism. Maxwell first pointed out that Ampère's law of electromagnetism can be stated as follows: The magnetomotive force around any closed curve, or circuit, in the magnetic field produced by electrical currents is equal to 4π multiplied by the electric current which flows through any surface bounded by that curve. This state ment of the law differs in form from that of Ampère, but it is equivalent to it. But whereas Ampère referred to electrical currents which represents motion of electricity in conductors, Faraday and Maxwell centered their attention not so much upon electrical charges as upon the tubes of force which they associated with them, 4π tubes per unit charge. Maxwell's hypothesis was that wherever these tubes vary there is an electrical current producing the same magnetic effects as the electrical conduction current studied by Oersted and Ampère. This hypothesis enabled Maxwell to formulate the second fundamental law of electrodynamics in a general way as follows:

Draw a closed curve in any part of space and consider the electric flux which is interlinked with that curve. The magnetomotive force around the closed curve is equal to the time rate of variation of this electrical flux.

The formal resemblance between these two fundamental laws of electrodynamics as Maxwell formulated them is certainly remarkable. The foundation of the first was discovered by Faraday, that of the second was the discovery of Oersted and Ampère, but the amplification of these foundations and the complete structure raised upon them is the work of Maxwell, the Newton of modern electrodynamics.

When Newton completed his formulation of the laws of motion of matter he was ready to reveal to mankind his discovery of the law of gravitation. When Maxwell completed his laws of motion of the electromagnetic flux he was ready to reveal to mankind a discovery which to Faraday appeared as a mere dream, but which to Maxwell was a reality. The discovery was the electromagnetic nature of light. Maxwell's two fundamental laws in electrodynamics lead directly to the result that electromagnetic dis-

turbances are propagated through various media with the same velocity and in the same manner as light, and since we can predicate the same things for the propagation of one as for the propagation of the other we are justified to consider the two as identical. This is what Maxwell did and when he did it the great electromagnetic theory of light was born.

This was the message which Faraday and Maxwell had to deliver to the world. Faraday began to formulate his message when he discovered the magnetic rotation of the plane of polarization of a beam of light; he went a step further in his historical discourse on "Thoughts on Ray Vibrations." Maxwell delivered the message but the world needed over thirty years to grasp its full meaning. Hertz's classical experiments of 1887 were the first to reveal and to illustrate this meaning to the unbelieving world.

Maxwell's Electromagnetic Theory founded upon the work of Oersted, Ampère, and Faraday was meant to embrace the phenomena of electricity in motion and the phenomena of light. Recent advances in electron-physics and in radiation justify the hope that Maxwell's Electromagnetic Theory will lead to a more complete knowledge of the constitution of matter than man ever dreamt of prior to Oersted's and Ampère's discoveries.

The Centennial of the Discoveries of Oersted, Arago, and Ampère

BY C. E. MAGNUSSON

Professor of Electrical Engineering, University of Washington, Seattle.

IT is eminently fitting that the Pacific Coast members of the Institute, in convention assembled, should pause in their labors on present day problems and consider the significance of this day and year as the hundredth anniversary of the fundamental discoveries of Oersted, Arago, and Ampère. One hundred years ago today, the 21st of July, 1820, Oersted announced his notable discovery of the directive effect of the electric current on the magnetic needle; this year is likewise the centennial of Ampère's brilliant achievement in determining the laws of electrodynamics.

With present day knowledge of electric phenomena, the basic importance of Oersted's and Ampère's discoveries is readily understood, but in order to appreciate the magnitude of their achievements, it is necessary to have a sympathetic understanding of their environment, to keep in mind the prevalent scientific theories and the views of their contemporaries, and to realize how little was known of electric and magnetic phenomena. To reach this point of vantage requires effort—particularly for electrical engineers. We give little thought to what happened yesterday. Our minds dwell on coming events. Out watchword is "What is new?" Our interest lies at the front, and we eagerly discuss the latest advances in the electrical field. What was discussed last year is now an old story. It is surprising how seldom we find it necessary to look back even ten years in our technical journals. Verily, the electrical engineer lives in the future.

In order to more readily sense the "atmosphere" in which investigators in the electrical field labored in 1820, and to better perceive the frontier of scientific knowledge, the dividing line between the known and the unknown, it may be advisable to briefly call attention to some of the salient points—a few landmarks in the scientific world of their day.

Europe was slowly recovering from the devastations of the Napoleonic Wars, which had closed with the battle of Waterloo in 1815. After a century of diplomatic intrigue, misgovernment and revolution, Europe had entered upon a period of material and intellectual development. The use of steam was rapidly increasing in importance as an industrial factor. Watt had finished his labors; Fulton had successfully applied steam to navigation (1807); and Stephenson had invented the locomotive (1814); but the first steam railway was not built until 1830. The caloric theory of heat still held sway, although Rumford, Young, and Davy (1812), had already proved experimentally that "the immediate cause of heat is motion, and that the laws of its communication are precisely the same as the laws of motion." The controversy between the partisans of the emission and undulatory theories of light was at its heighth, with Biot, Poisson and Laplace championing the former and Fresnel, Arago and Young the latter. The atomic theory and Dalton's law of multiple proportions had been firmly established by the comprehensive and extraordinarily accurate determinations of the atomic weights by Berzelius. In 1807 Davy had decomposed the alkaline salts by electrolysis and produced metallic sodium and potassium.

Although magnetic and electrostatic phenomena had received much attention during the 18th century, the known facts were few and isolated. In a notable series of experiments, using the torsion balance,

*Address delivered at the Pacific Coast Convention of the A. I. E. E. Portland, Oregon, July 21, 1920.

Coulomb had determined the laws governing the action between electrostatically charged spheres; and in 1790 Galvani had observed the physiological effect of contact voltage as indicated by muscular contraction. It was, however, not until 1800 that Allessandro Volta invented the voltaic pile, and thus provided a means for producing galvanic electricity or electric currents. Although large primary batteries of copper-zinc elements with dilute solutions of sulphuric and nitric acids as electrolytes were constructed and used by many physicists, it took twenty years before the next milepost of progress in the electromagnetic field was erected. Early in the year of 1820, Johannis Christianus Oersted[1], Professor of Natural Sciences, University of Copenhagen, observed, while lecturing on electricity, galvanism and magnetism, the motive effect of a galvanic current on a nearby magnetic needle. For several months he conducted an extensive series of experiments to determine the laws of the observed phenomena. Realizing the importance of his discovery, he described the experiments in a carefully prepared report, and stated in concise form the laws governing the conflict between galvanic electricity and the magnetic needle. The pamphlet written in Latin and entitled, "Experimenta Circa Effectum Conflictus Electrici In Acum Magnetican," was published on the 21st day of July, one hundred years ago today. The essential part of Oersted's discovery can best be given by a quatotion from his original announcement.[2]

The opposite ends of the galvanic battery were joined by a metallic wire, which, for shortness sake, we shall call the uniting conductor, or the uniting wire. To the effect which takes place in this conductor and in the surrounding space, we shall give the name of the conflict of electricity.

Let the straight part of this wire be placed horizontally above the magnetic needle, properly suspended, and parallel to it. If necessary, the uniting wire is bent so as to assume a proper position for the experiment. Things being in this state, the needle will be moved, and the end of it next the negative side of the battery will go westward.

The uniting wire may change its place, either towards the east or west, provided it continue parallel to the needle, without any other change of the effect than in respect to its quantity. Hence the effect cannot be ascribed to attraction; for the same pole of the magnetic needle, which approaches the uniting wire, while placed on its east side, ought to recede from it when on the west side, if these declinations depended on attractions and repulsions. The uniting conductor may consist of several wires, or metallic ribbons, connected together. The nature of the metal does not alter the effect, but merely the quantity. Wires of platinum, gold, silver, brass, iron, ribbons of lead and tin, a mass of mercury, were employed with equal success. The conductor does not lose its effect, though interrupted by water, unless the interruption amounts to several inches in length.

The effect of the uniting wire passes to the needle through glass, metals, wood, water, resin, stoneware, stones; for it is not taken away by interposing plates of glass, metal, or wood. Even glass, metal, and wood, interposed at once, do not destroy, and indeed scarcely diminish the effect. The disk of the electrophorous, plates of porphyry, a stoneware vessel, even filled with water, were interposed with the same result. We found the effects unchanged when the needle was included in a brass box filled with water. It is needless to observe that the transmission of effects through all these matters has never before been observed in electricity and galvanism. The effects, therefore, which take place in the conflict of electricity are very different from the effects of either of the electricities.

If the uniting wire be placed in a horizontal plane under the magnetic needle, all the effects are the same as when it is above the needle, only they are in an opposite direction; for the pole of the magnetic needle next the negative end of the battery declines to the east.

That these facts may be the more easily retained, we may use this formula—the pole *above* which the *negative* electricity enters is turned to the *west*; *under* which, to the *east*.

It is difficult in our day to appreciate how strange and unaccountable the phenomena appeared to Oersted and his contemporaries. Not until eleven years later did Faraday make his epoch-making discovery of electromagnetic induction and give "chart and compass" to explorers on the electromagneto-dielectric main, by his conception of the now indispensable magnetic and dielectric lines of force. We are so accustomed to use the lines of force when thinking of electromagnetic phenomena that without this concept we are entirely at sea. Conceive, if you can, some rational explanation of the strange action of the magnetic needle in the presence of a conductor carrying an electric current without using Faraday's concept of magnetic lines of force.

The news of Oersted's discovery was brought from Geneva to Paris by the celebrated physicist Dominique Francois Jean Arago, who repeated the experiments before the French Academy on September, 11th. Among the savants present at this meeting was Andre Marie Ampère, professor of Analysis in the Polytechnic Institute in Paris. Seven days later Ampère presented a most remarkable paper before the Academy, announcing new discoveries of far reaching importance. He described a series of ingeniously devised experiments showing the action of one electric current upon another, and formulated the fundamental laws of electrodynamics. Two parallel and like directed currents attract each other, and two parallel electric currents flowing in the opposite direction repel each other. He proposed the elegant molecular electric currents theory as an explanation of magnetic phenomena and the interaction of electric currents with the magnetic needle. For many years physicists had looked for an explanation of electricity as a form of magnetism, but Ampère showed that, contrary to expectations, magnetism was due to electric currents. In the same paper he gave a remarkable mathematical analysis of the observed phenomena, which offered a theoretical explanation of the interconnection between magnetism and electric currents.

In one short week Ampère had accomplished more than all his predecessors and laid a firm foundation

1. In Danish, Hans Christian Orsted.
2. English Translation, Annals of Philosophy, Vol. XVI., p.274, London, 1820.

for extensive developments in the electric field. Whether we consider the clearness and convincing power of his mathematical analysis, the ingenuity and skill displayed in the experiments, the elegance of his molecular electric current theory, or the marvelous rapidity with which the work was accomplished, Ampère's achievement is of the highest order.

A few days later Arago observed that iron filings cling to a wire carrying an electric current but drop off when the circuit is broken. Arago and Ampère working together showed that a helix of wire carrying an electric current around a bar of iron or steel would make the bar strongly magnetic. Thus the modern electromagnet was invented. These discoveries of Oersted, Ampère and Arago advanced the knowledge of the laws governing electric circuits far ahead of what was known of magnetism and static electricity.

In commemorating the centennial of a scientific discovery, our interest necessarily centers on the phenomena observed, the theories advanced, and the importance of the laws established. In contemplating these discoveries, one is filled with admiration over the originality and clarity of thought, the initiative, and the constructive imagination of the investigators. However, acceptable homage is not paid by adulation but by an ardent desire to help in extending the realm of human knowledge. The centennial celebration of great scientific discoveries should add to our zeal and be an inspiration to all workers in the vineyard.

The conditions for scientific research today are very favorable as compared to a century ago. The available funds are enormously greater, the equipment better, and an army of workers is now engaged in extending human knowledge in place of a few knight-errants of old. The economic importance of research in the manufacturing industries is the mainspring for most of the support, but even pure research is progressing on a scale hitherto unknown. The relative importance of the universities and industrial research laboratories as centers of scientific thought and intellectual progress is indicated by the importance of the discoveries made and the number of notable papers presented before the learned societies. The most favorable conditions in practically all fields are now found in the United States, a fact which presages future leadership for our country in intellectual achievements.

But if we take a smaller division and consider the conditions on the Pacific Coast, which is of special interest to us, the situation is far from flattering. The amount of research in progress in the Golden West is a negligible quantity as compared to that of the whole United States. The material aids to research, funds and apparatus, are distressingly inadequate for the successful prosecution of research, and the young men of initiative and research talent go east to the well-equipped laboratories of industrial plants and research foundations. The quickening power of research to manufacturing is not appreciated by western captains of industry, and the huge enrollments of undergraduate students in our universities is a handicap to productive scholarship in our seats of learning.

But the West is the land of promise. Here the scientific investigators, the creative thinkers must carry on and realize the dreams of the pioneers. The discoveries of Oersted, Arago and Ampère, the wisdom and knowledge of the ages, are our heritage; the unlimited possibilities of the future, our opportunity.

MUNICIPAL PLANT OPERATED BY PRIVATE INTERESTS

Private operation of a municipally owned plant is rather a rare combination. It is being tried out in Alameda, California, as a result of the power shortage in that state. Recently the Alameda Municipal Power Plant closed down and its machinery was packed in oil and waste to prevent deterioration, the municipality having found that it could purchase power much more cheaply from the Great Western Power Company than it could be produced with fuel oil at its present high price. During the last few weeks the power shortage has become so acute that the power companies of that section, in order to fulfil their contracts, sought to have the municipality of Alameda resume generating its own power temporarily. This it refused to do, but did agree to operate its power plant with its own employees and use the current so generated, turning over to the Pacific Gas and Electric Company, for use elsewhere, the current the city was securing from the Great Western Power Company. Alameda continues to pay the Great Western Power Company for power, while the Pacific Gas and Electric Company is paying the cost of putting the Alameda municipal plant back in service, and all costs of operation, and, when the present emergency has passed, will pay the cost of putting the plant out of service. This evidences two things: First, that the central station, when necessary, will do everything in its power to supply service to its customer; and second, that another municipality has definitely abandoned its municipal light and power plant, even though that plant is in excellent condition.—*N. E. L. A. Bulletin.*

The Electric Melting Furnace

The Early History of the Electric Melting Furnace and its Development into Various Commercial Types.

HISTORY OF THE ELECTRIC FURNACE

BY JOSEPH W. RICHARDS
Professor of Metallurgy in Lehigh University

What I am going to tell you is not new, but it will supply a background for the following papers by stating some of the historical relations in the development of the electric furnace.

About 1877 Siemens got the idea that it would be possible to melt steel commercially by the use of the electric arc. He spent a great deal of money and exercised a good deal of ingenuity in trying to melt steel in a crucible by means of the electric current. He tried this in two ways: First of all to melt the steel by radiation from an arc, and second by making the steel one pole of an arc.

He took a crucible, bored holes in the sides near the top, put electrodes through these holes, placed the metal in the bottom and a lid on top and then started an arc, melting the steel by radiation. That was the first arc-radiation furnace.

He also took a crucible, using but one electrode passing through the lid and making the steel itself one of the electrodes of the arc. The upper electrode was comparatively easy to design, but the lower electrode (to take the current away from the steel itself) was the cause of trouble. He bored a hole through the bottom of the crucible, reinforced it outside by a block of concrete, and screwed in a sort of a plug of soft iron. He relied upon this for carrying away the current, it being in contact with the melted steel inside and cooled by the air outside. His proposition attracted much attention. In some cases he obtained a thermal efficiency as high as 50 per cent.

He tried to make this furnace run commercially, but it did not prove effective due to the uncertain nature of the iron connection through the bottom. He spent a great deal of money trying to make it a commercial success, but was unable to do so. He did, however, get some fairly high thermal efficiencies, but his apparatus was not good enough for commercial use. That sums up in a few words what Siemens tried to do and what he accomplished.

The next to experiment with the electric furnace to melt steel by radiation from the arc was Captain Stassano of the Italian Army. He built a furnace four feet in diameter and three feet high, with three electrodes passing in through the upper parts of the walls, coming together in triangular formation above the bath, and using a three-phase arc. The furnace was capable of holding about a ton of steel. It was used commercially in Turin, Italy. Because of the cheapness of power—\$12.00 per h.p.-yr.—and with scrap steel at about \$5.00 per ton, he was able to charge his furnace, melt down the steel, pour it into castings, and successfully compete with the steel made in open-hearth furnaces or in Bessemer converters. This was a direct development of Siemens' idea—melting by radiation from an arc. From forty to fifty furnaces of this type are at present in operation throughout the world.

There are other furnaces of a somewhat similar character, heated by radiation from the arc. Sometimes the arc is changed a little in shape. Such a one is the Rennerfelt furnace, which is essentially of the same general type, though differing in details. It consists of two horizontal and one vertical electrodes, which project the arc like a blowpipe on the surface of the metal.

There are still other types of the arc furnace. There is the rocking arc-furnace, in which the electrodes pass through the sides of the furnace, but the metal is rocked so that it is uniformly heated, thus combatting unevenness of temperature caused by intense heating near to the arc. This particular modification of the arc-radiation furnace has been found very useful in the melting of alloys containing volatile metals, such as, particularly, brass.

The other type of furnace devised by Siemens, with the arc passing from the electrode to the metal, is known as the arc-resistance furnace. In such furnaces the larger part of the energy which melts the metal is generated in the arc. This idea was first worked commercially by Girod, a Swiss electrical engineer, who conceived the idea of taking a regular saucer-shaped, steel-melting hearth and putting through the bottom of it a large hole, through which was inserted a soft, low-carbon steel rod. The electrode passing through the hearth was eighteen inches long; in running it melted six inches and left twelve inches solid. This automatically sealed it, and the current was taken away from the projecting end outside, which was water-cooled. One or more of these heavy electrodes was arranged in parallel through the bottom of the hearth. Ten, twelve, and even twenty-ton furnaces are in operation on this design. All grades of steel are successfully made in these furnaces. The Bethlehem Steel Company runs a ten-ton Girod furnace, melting cold charges, at Bethlehem.

Keller, in France, is making steel for the French Government with a modification of Girod's idea. He built a furnace in which he distributed electrodes in the hearth by taking a plate and putting it in the

bottom of the furnace under the refractory material, and attaching to it a number of half-inch rods which came up to the working surface where the metal lay. The refractory material was rammed around these rods. He had two to three hundred half-inch rods forming a regular grid coming through the bottom of the furnace to which electrical attachment was made, ramming in between them broken carbon in order to make the mass more conductive. If he rammed in carbon alone it would be dissolved out by the steel and the bottom would keep coming up, so he used a mixture of carbon and magnesite, which proved very satisfactory, covering it up with a surfacing of magnesite. He built a large number of furnaces which have operated very satisfactorily with this grid of electrodes embedded in the bottom.

Someone then thought: "Is not the material of the hearth conductive enough, when hot, to carry the current?" The first furnace of that type that I saw was in operation in Sheffield, England. The method followed was to take a grid electrode and embed it in the hearth, leaving the prongs embedded but not quite reaching through the hearth to the metal above it. When cold, this refractory layer was an insulator, but when hot a good enough conductor; and so a direct electric connection between the bottom electrode of the furnace through the hearth material to the metal bath was formed.

The hearth material itself becomes impregnated with oxide of iron during use, and thus becomes better conducting, so much so that the furnace can be started up cold. Electrical connection is thus formed through the material which forms the basic hearth itself.

A number of furnaces have been designed on this principle, with the electrode embedded in the bottom of the hearth. They are sometimes built with the hearth electrode of graphite and iron, or of iron with graphite terminals, embedded in the hearth material, with the hearth material packed and rammed in on top of it. These furnaces are further developments of Siemens' idea of taking the current off from the bottom of the containing vessel.

The Heroult arc furnace uses two electrodes—one to put current into the charge and the other to carry it away. The idea is to have two arcs in series, to have current passing from one electrode through the slag to the metal, through the metal, and thence back to the other electrode. With very cheap power, labor, and scrap material available, Heroult was in a position to make very large profits, and founded a successful steel business. Heroult did more perhaps than anyone else to make electrical steel commercial.

Heroult also devised and obtained French patents for a combined furnace, which was intended for use as a Bessemer converter and electric furnace. His electric furnace was similar in shape to the open-hearth furnace, except that it was heated by electrodes passing through the roof. He interested the U. S. Steel Corporation in his patents and sold them for a large sum. The U. S. Steel Corporation has actively made use of them itself, and has also built furnaces for other people. The furnaces are splendidly designed, as well as being on a good working principle. The type having two electrodes and two arcs has been largely replaced by those having three electrodes and three arcs, for the latter three-phase type is the cheaper and more adaptable form of furnace. There are about two hundred and fifty of these furnaces in use in the United States.

There is another type of furnace which does not use the arc—the resistance furnace, where the metal is heated by the resistance of a solid or liquid material. There are a number of such furnaces. The first was devised by Gin, who used simply a ractangular hearth provided with a long serpentine groove connected with two heavy terminals, and capable of carrying a very heavy current. The object was to melt down the metal by its own resistance, and to keep it at the proper temperature. Nothing but the resistance of the metal itself, lying in the groove, was relied upon to melt it and keep it at the correct temperature while being refined.

The resistance-radiation furnace is one where the metal is heated by radiation from the resistor, the latter being heated by the direct passage of the current. That is the principle of the Bailey furnace which is used for heating bars and ingots and for melting metals such as brass, but not yet for melting steel. The channel filled with broken carbon is just beneath the roof of the furnace, which collects the heat generated as it is reflected against it, and radiates it back onto the charge on the hearth.

There is another type of this resistance furnace where the material to be melted is put in crucibles and the conducting material by which it is to be heated (the resistor) is packed around the crucibles. This type of furnace does not, however, find much popularity, for it has defects and shortcomings which prevent it from becoming a commercial success, though it is very satisfactory as a laboratory furnace.

There is a type of resistance furnace which depends upon the pinch effect. Liquid metal in small channels communicating with a larger bath of metal, is heated by its own resistance. This is the basic principle of the Hering furnace. The electrodes carrying current to these channels are water-cooled. This type of furnace has received many modifications, among which is the use of current generated in the tubes by induction, so doing away with electrodes (Ajax-Weil-Hering furnace.) This introduces complications, but yet it has merit by doing away with electrodes, and is now in successful operation.

The induction furnace is also a resistance furnace; it was originated by Mr. Colby, of Newark. He thought it possible to melt metal by means of induced

currents. He experimented at the General Electric Company laboratories and took out patents, but never brought it to a commercial outcome. Ferranti conceived the same idea in England at about the same time. The first to use this idea commercially was Kjellin in Sweden, about 1902. He used bars of steel which had been made in other furnaces, merely melting them down in this furnace which he used as a melting crucible. He built a small furnace of 500-pound capacity, then one of 1000-pound, and made steel in large quantities.

The Germans (Roechling and Rodenhauser) took up the idea and increased the size of the furnace by multiplying it—making a combination furnace of two circles. Even a three-circle furnace run by three-phase current, has been devised.

It is a great feat to construct these complicated furnaces and to get them to work—to melt steel and yet to keep the coils cool enough so that their insulation is not destroyed. The principal drawback with this type of furnace is its lack of exposed metal surface, so that it is difficult to refine material in them. They are also very expensive, and an accident to them is a very serious matter.

There is a type of induction furnace which has recently been brought out by Dr. Northrup, with rapid oscillating current, which does not need a magnetic circuit, and so is simpler in design. It has many advantages over the ordinary type of induction furnace, but has also some complications not found in them. It has reached the laboratory stage and is developing hopefully toward the commercial field.

Electric Furnaces for Non-Ferrous Metals

The metals particularly in mind are brass and bronze, copper and aluminum being secondary in consideration. Brass contains zinc, a metal fairly volatile at a bright red heat. The considerable loss of zinc by volatilization must be guarded against. If brass is made in an electric furnace of the proper construction, volatilization and oxidation of zinc may be reduced to a very small amount (1 to 3 per cent).

The radiation furnace, which radiates heat directly on the metal, is very inefficient for this sort of work, boiling out the volatile materials very rapidly from the part of the surface which becomes over-heated. This disadvantage of the arc-radiation furnace has been overcome by active circulation—rocking of the furnace or circulation of the bath, thus keeping the metal at a uniform temperature. This principle is being utilized very efficiently in brass furnaces, which work by arc radiation and yet lose very little zinc by volatilization.

Having now in very summary fashion outlined the electric furnace art, particularly its development in the direction of melting metals, such as steel and brass, I will leave the field to the special writers who will tell of the particular construction and operation of their several types of electric melting furnaces.

THE GREAVES-ETCHELLS FURNACE

BY F. W. BROOKE

Electric Furnace Construction Co., Philadelphia.

The Greaves-Etchells system suses the delta-Y connection, which is admittedly the best combination for producing evenly loaded phases. The transformers are connected delta on the primary side and Y on the secondary. One of the legs of the transformer is applied directly to the bottom of the furnace by means of copper busbars and a copper plate, which conducts the current through a bottom composed principally of magnesite and dolomite, in such a way that there is a graded resistance, beginning with a low resistance and ending high. The other two legs of the transformer are connected to movable electrodes, which extend down through the roof. Regulation is then maintained by the usual types of furnace regulators. It is readily seen that by this arrangement there is no possibility of either movable electrode ever touching the bath or extending into it, without causing a short circuit. This feature alone is very valuable, and one which is very hard to handle in a large number of other types of furnaces.

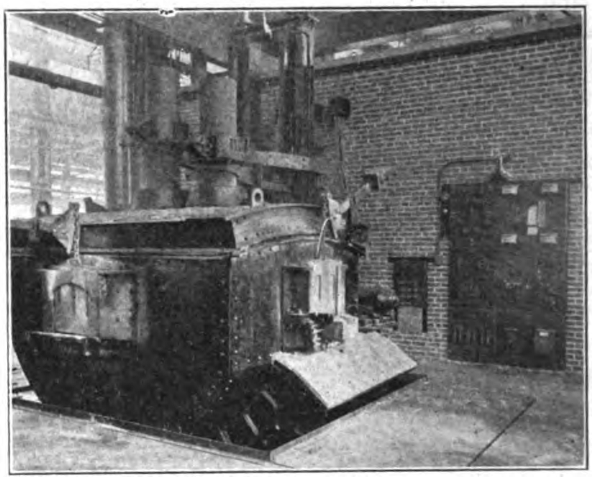

Fig. 1—Greaves-Etchells Three-Ton Electric Furnace, Showing Control Board

By a careful analysis of the conditions described above, it will be noted that the combination of a resistive bottom and the delta-Y connection of transformers is one which prevents serious overloading of one phase, at the same time doing away with a specially high reactance, which is necessary on other makes of furnaces.

Metallurgically, a furnace which uses the bottom as a resistor, and therefore as a heat producer, is superior

to one which generates all the heat above the bath. This is especially true of the production of alloy steel, where materials are used which have a higher specific gravity and also higher melting point than the steel itself. Rabbling becomes unnecessary in the Greaves-

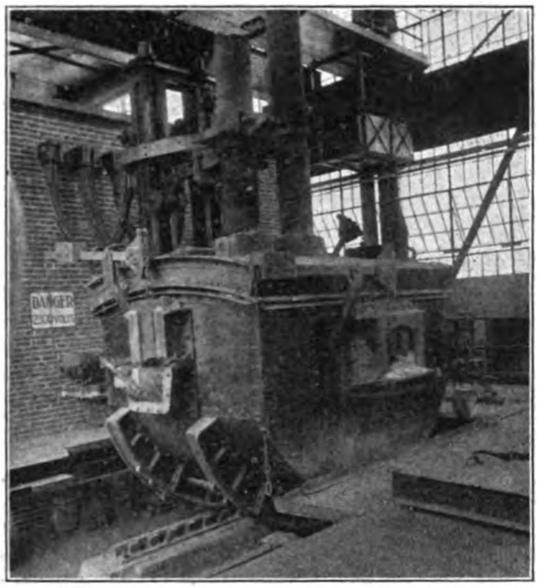

Fig. 2—Greaves-Etchells Three-Ton Electric Furnace, in New Foundry, Navy Yard, Philadelphia, Showing Rocking Device

Etchells furnace, and the roofs last longer, since they are not punished so severely. Two voltages are used, the high voltage for melting down and the lower for refining.

A study of the shapes of the lining of the electric furnaces of the arc type now in commercial use, brings out many practical points which tend to give power economy and added life to the refractory side walls of the furnace. The first and most important point

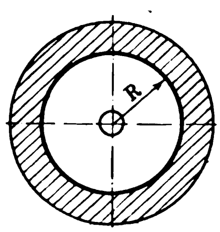

Fig. 3

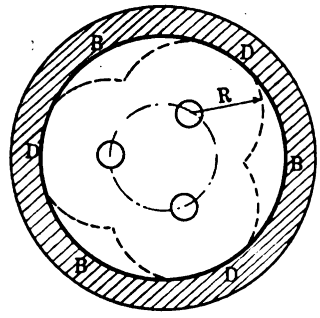
Within heavy line represents metallic bath. Sectioned areas represent refractory sidewalls.

to bear in mind is that heat generated in the electric arc will be dissipated radially in the horizontal plane from the center line of the electrode, from which we see, on referring to the illustrations herewith that Fig. 3 would give the most ideal shape. In this shape, the cold metal would be uniformly melted, that is, that with uniform scrap charged evenly into the furnace every piece of scrap lying on the outer edge of the lining would melt at the same time, and in practical language, there would be no "cold spots" or "hot spots."

This shape was used in the early single-phase furnaces, but had the very obvious disadvantage of being only applicable to single-phase furnaces, which today are no longer being considered by either the prospective buyer or the power companies who supply the power.



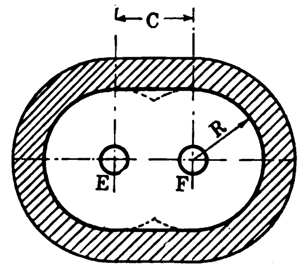


Fig. 4 Fig. 5

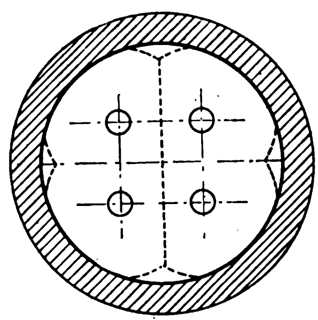
Within heavy line represents metallic bath. Sectioned areas represent refractory sidewalls.

Applying these views to circular furnaces, so generally adopted by the "three-top-electrode" furnaces, as shown in Fig. 4, it will readily be noted that when the cold scrap has become melted at the points A, there will be decided areas or masses of unmelted scrap at the points B, and were it practically possible, such a furnace would require a three-leaf shamrock shape to give ideal conditions. This, however, is not practical, and in order to melt the whole of the



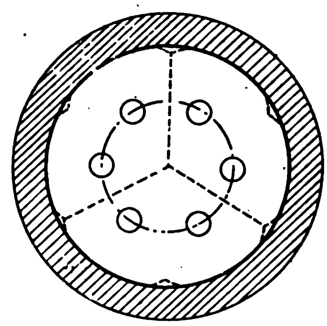


Fig. 6 Fig. 7

Within heavy line represents metallic bath. Sectioned areas represent refractory sidewalls.

charge in furnaces of this design, it becomes necessary to superheat certain parts of the charge, which means extra expenditure of power, and develops three very decided hot spots at points A, with its corresponding damage to the lining.

The designers of the three-phase furnaces (three-phase current being now in general use) which have two (or multiples of two) electrodes carried through the roof (the third phase of each bank being connected directly to the conductive hearth)are in a better position to avoid these wasteful hot and cold spots, particularly in the two-electrode and six-electrode type

of furnaces, and proportionately so in the four-electrode type.

Referring to Fig. 5, where the oval type of lining is used, it will be noted at first sight that there would be a tendency for two small cold spots to develop, but in actual practise this is not the case, as the heat dissipated from, say, electrode E is carried away radially and uniformly through the charge and a certain percentage through the lining, except in the direction of the electrode F. In this direction the heat is dissipated through the charge but is then "heat insulated" by the heat being dissipated by this electrode F. By arriving at a certain balance of the distance C, the ideal conditions of Fig. 3 can be obtained with a three-phase load.

Referring back to conditions enumerated in Fig. 4, it will be readily seen that as the number of electrodes for a circular furnace are increased, the conditions of hot and cold spots are gradually reduced as shown in Figs. 6 and 7. Shapes shown in Figs. 5, 6 and 7 are used in the Greaves-Etchells design.

MOORE RAPID "LECTROMELT" FURNACE

BY R. D. THOMAS
Pittsburgh Electric Furnace Corporation

In considering the steps in the advancement of a new process of manufacture the fundamental reason for the introduction of the new process is sometimes lost sight of. A discussion of the electric furnace for the manufacture of high-grade steel immediately raises the question as to why the older steel making processes are now being replaced.

Some years ago all high-grade steel was made by the crucible process. In this process pure steel scrap is charged into a pot holding about 100 pounds and melted. The resultant steel has the analysis of the mixture charged, no impurities being removed. This process has all the disadvantages of small quantity production plus very expensive raw material. In more recent years the open-hearth method has been perfected to a point where comparatively high-grade steel is produced. In this process the steel is melted on an open hearth by the heat of burning fuel impinging on the surface of the bath. The refining of the steel, that is the reduction of phosphorous and, to a minor extent, the removal of sulphur, is done in this process, but the refining processes are constantly handicapped by the avidity with which the molten steel picks up from the fuel the very impurities which the metallurgical reactions are removing, and the inability to maintain a reducing atmosphere and very high temperature necessary for the effective removal of the sulphur.

The heat being applied as fuel burned above the bath, places severe punishment on the roof refractories. This, in turn, necessitates the rather slow application of the heat to prevent burning down the furnace. As a consequence the average open-hearth heat is in the furnace from 8 to 15 hours, depending on the kind of steel being produced. As a corollary it will be noted that the output of a 30-ton open-hearth furnace will be in the neighborhood of 50 tons per day.

The electric steel furnace of the rapid type comes into competition with these two older steel-making processes and shows many advantages, some of which may be listed briefly:

1. Neutral heat which has no effect on the metallurgical reactions of the steel-making process. The atmosphere in the furnace chamber may be made oxidizing or reducing at the will of the operator.

2. The application of the heat directly to the bath permits of a much more rapid application of heat than in the open hearth without the destruction of the refractories.

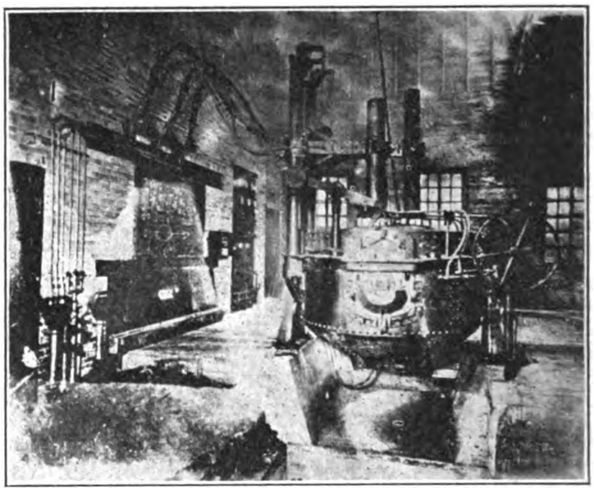

Fig. 1—One and One-Half Ton Moore Electric Steel Furnace

3. The reduced time to make a heat reduces the furnace capacity required for a given daily output. Some makers of electric steel furnaces take especial advantage of this feature and there are three-ton electric furnaces in operation which makes as much steel in a day as, or more than, a 30-ton open hearth.

4. Better quality steel can be produced in the electric furnace than in the open hearth. Electric steel is equal to the highest grade of crucible steel and, due to the fact that the heats are larger, it is more uniform in quality.

5. Electric steel can be pre-heated to temperatures higher than can be obtained in the open hearth or crucible, and the greater fluidity obtained makes for decidedly better steel castings, especially where the casting is of thin cross-section.

The best type of electric furnace for steel making is generally conceded to be the one with the arc struck between the electrodes and the bath. Three electrodes are usually employed. While this general type is followed by most of the present manufacturers of elec-

tric furnaces there are very wide variations in the design of the various furnaces which make for the wide differences in operation. These differences do not generally affect the quality of the steel produced. A good operator can make high-grade steel in the crudest "home-made" furnace, but the electric furnace to be commercial must conform to certain standards of economy of investment and operation. It must likewise be as near foolproof as possible, easy of repair, rapid and reliable in operation.

The furnace shown in Fig. 1 has certain features worthy of special note. The inverted dome-shaped bottom of the furnace prevents any possibility of floating the furnace bottom through the expansion of the shell, as the bottom refractories are arched in place. A practical feature of considerable importance is the absence of all mechanism from the furnace pit. The tilting mechanism, instead of being placed under the furnace, is placed above the floor and the tilting motor is mounted on a bracket to the side of the furnace where it is easily accessible and out of harm's way from molten steel slag and dirt. The electrode winch motors are placed in the transformer room and are away from all the dirt, heat, water and dust which is always present where they are mounted on a furnace. (Fig. 2).

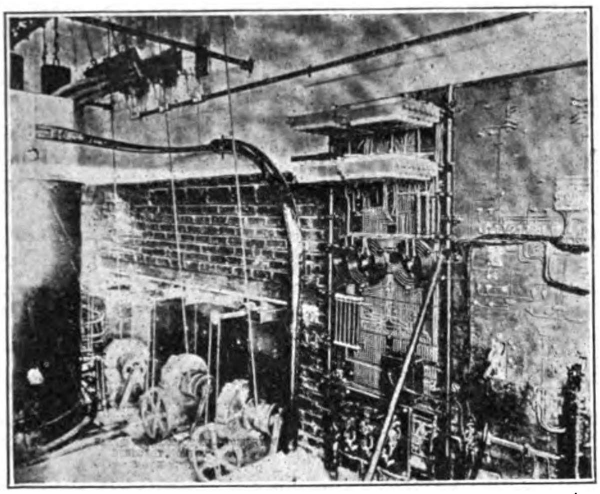

Fig. 2—Rear of Power Board Showing Location of Electrode Winch Motors

The conducting arms of this furnace are also the electrode supporting arms, a fact which permits placing the insulation between the furnace shell and the arms back at the supporting columns where it is not subject to the rapid deterioration from the heat above the furnace. This composite electromechanical electrode arm avoids the cumbersome duplicate electrical arm with mechanical arm to carry the electrodes heretofore used.

The distinctive feature of this furnace is its rapidity of operation which also spells efficiency and output. During the melt-down period there are no metallurgical reactions which require appreciable time, so that any reduction in the melt-down time correspondingly reduces all heat losses. The usual time of melt-down in this furnace is one-half hour to three-quarters of an hour, and a heat of casting steel heat may be produced from cold metal in one hour or less. This rapid melt-down feature is not obtained merely through the use of comparatively higher capacity transformers, but the whole design of the furnace is such that it will take care of the rapid power input. That the design is successful in this respect is proved by roof lives of more than 200 heats and power consumption on individual heats as low as 380 kw-hr. per ton. Another advantage of the rapidity of action is the greater output per ton of furnace capacity. This means that a smaller furnace, with an attendant lower investment, is required for a given daily output. Generally speaking the capacity of this high-powered furnace is approximately one-half that of the average-powered electric steel furnace for the same daily output.

The question of power factor is one that is of constant interest to the power companies. Some electric steel furnaces run as low as 50 per cent with the majority having a power factor between 80 per cent and 90 per cent. There is no design reason why the power factor cannot be made above 95 per cent, but there is a very practical consideration which will make a power company reluctant to connect up a furnace with too high a power factor. During the first portion of the melt-down there is a period—short or long depending on the speed of operation of the furnace—when momentary short circuits occur. The value to which the current will rise on these momentary short circuits varies greatly with the power factor. The lower the power factor the less will be the line disturbance. Power plants not having a large reserve may find it desirable to have their furnace load at power factors in the neighborhood of 70 per cent to prevent undue fluctuations in the load. However, as previously stated, the majority of furnace installations are best designed for average central-station conditions for a power factor of 80 per cent to 90 per cent.

WEEKS ELECTRIC FURNACE

BY S. H. OURBACKER
American Metallurgical Corporation, Philadelphia.

Industrial heating is divided into three classes—namely

Low Temperature, ranging up to 750 deg. fahr.

Medium Temperature, ranging from 750 deg. fahr. to 1700 deg. fahr.

High Temperature, ranging from 1700 deg. fahr. up.

The lower range of heat is applied to drying, japanning, vulcanizing, core baking, general heating of liquids and melting of low-melting-point alloys.

The medium range of heat is applied to melting of non-ferrous metals, heat treating, vitreous enameling, annealing, carbonizing and case hardening.

The higher range of heat is applied to the melting of metals of high melting point such as steel, brass, ferro-alloys, etc.

In the lower range electric heat is produced by the use of resistance ribbons running at black heat or at a slight glow. In japanning where explosive gases are produced, the oven is ventilated by an exhaust fan. In core baking or other baking or drying applications, the ventilation is regulated according to the explosive or objectionable nature of the gases emanating from the work.

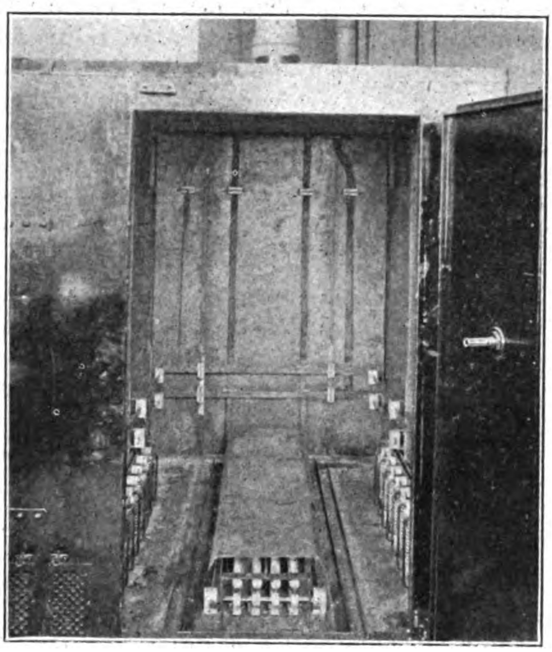

FIG. 1—INTERIOR VIEW OF ONE COMPARTMENT OF THREE-COMPARTMENT TUBE BAKING OVEN, SPRAGUE ELECTRIC WORKS, Bloomfield, N. J.

Each compartment 3 ft. 6 in. wide, 6ft. deep, 6 ft. high, 17 kw. connected.

In the medium range of heat, resistance ribbons are used running at high temperatures and radiating the heat to the work. No ventilation is used in this type and the furnaces are carefully bricked and heat-insulated to give as low a radiation as possible.

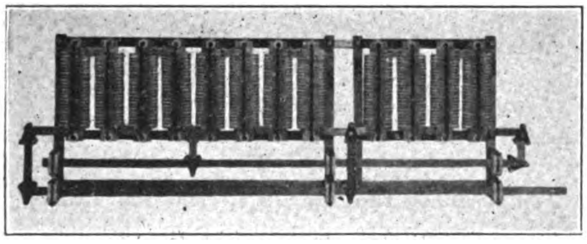

FIG. 2—METHOD OF MOUNTING AND CONNECTING WALL-MOUNTED HEATERS

In the higher temperature, heat is usually produced by electric arcs either of the open or smothered type, or either coke or carbon resistance.

Electric heating today is of extreme importance to all central stations from the standpoint of a desirable load. It is possible through electric heating loads to obtain a large power consumption. As an example, in one large manufacturing concern in this country there are 13,000 kw. of industrial electric heating installed. An average figure which is possible amongst small users of industrial electric heating, not including melting furnaces, would be in the neighborhood of 85 kw. per customer.

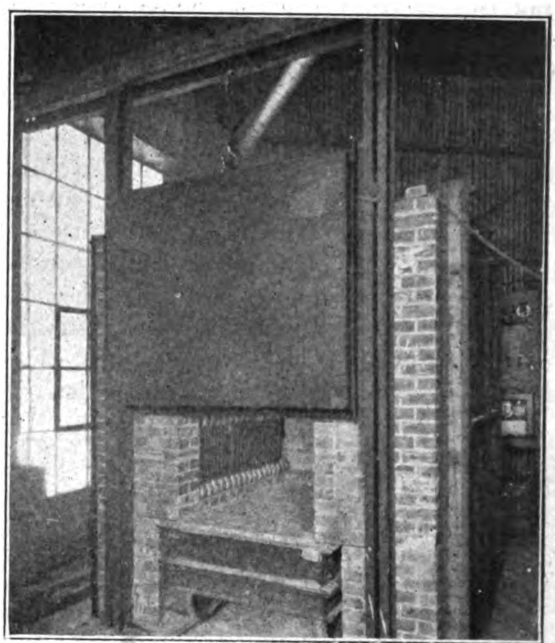

FIG. 3—ELECTRIC HEAT-TREATING FURNACE, CONNECTICUT ELECTRIC STEEL CO., HARTFORD, CONN.

52 in. deep, 36 in. wide, 32½ in. high, 40 kw., maximum temperature 900 deg. cent.

The advantages of electric heat are numerous. Some of it is produced at a high thermal efficiency as the power put into a furnace is transformed directly into heat and produced at exactly the points desired.

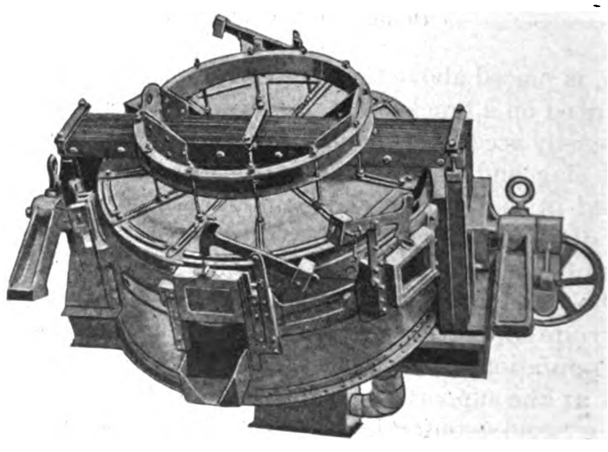

FIG. 4—500-LB. INDUCTION FURNACE

Absence of flues, objectionable gases and excessive heat radiated from the furnace, cleanliness, neatness of appearance and the advantages of temperature control, without the necessity of a skilled operator, are some of the chief advantages.

Fig. 1 shows the class of oven applied to the low-

temperature work. This type of oven is especially adapted for japanning and core baking, and drying work. The temperature is maintained constant by automatic heat-controlling instruments. With such an instrument it is unnecessary for the operator to make any adjustments after the proper temperature is set on the instrument, thus reducing the labor cost, as practically unskilled operators can be used.

Fig. 2 shows an illustration of the type of unit usually employed in low-temperature work. The heating element here is a non-corrosive resistance metal capable of long life.

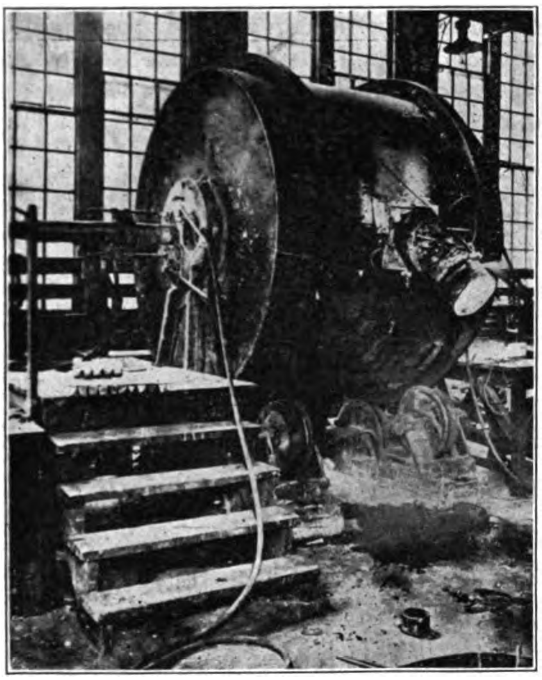

Fig. 5—Weeks Electric Rotating Furnace

Fig. 3 shows the type of furnace employed in the application of medium range heat. It will be noted that the furnace is of standard type of mill construction and that the heat units are placed on the side walls in place of burners as in oil-fired furnaces.

The heating ribbon is installed by placing in the lining of the furnace specially moulded refractory insulating blocks and hanging the ribbons upon them.

In the higher temperature work a number of different types of furnaces are employed. In the production of steel there is the arc and induction type, and as for brass there are a smothered arc, open arc and coke resistor types. Fig. 4 shows the latest development in this country on the induction furnace for the melting of steel. The writer wishes to point out the importance of this recent design as it appears to solve the difficulties which have been encountered in induction furnaces up to the present time. It is well-known that the induction furnace is the most desirable type of furnace to produce high-grade steels due to lack of contamination difficulties contributed to electrodes.

The great objection to the induction furnace has been the rapid circulation of the metal, which was caused by opposing electrical forces between the primary coil and the bath which is the secondary circuit. This circulation at such high temperatures will break down any refractory known, thus causing considerable lining trouble. This has been overcome in this design by placing a pancake coil directly above the bath so that the opposing forces have no tendency to rotate the metal. In order to insure proper mixing, the furnace is placed on trunnions and can be tilted slightly, thus varying the cross-section of the bath and causing any degree of rotation desired.

Fig. 5 shows the Weeks rotating brass furnace. This picture is an illustration of the first installation in this country, which was made at the works of the General Electric Company some eight years ago, and produced two tons of brass per heat. In this type of furnace the metal is melted by the open single-phase arc produced by horizontal electrodes passing through the center axis of the drum. It is necessary in using an electric arc for melting brass to keep the metal thoroughly mixed in order to prevent the zinc content from boiling out, since zinc volatilizes at a lower temperature than the melting point of copper. This has been accomplished by rotating the drum about the electrodes which constantly mixes the superheated surface with the colder metal at the bottom of the bath, thus keeping the bath at a uniform temperature and the zinc so well mixed with the copper that volatilization is a minimum.

A few words as to the power characteristics of the different types would be interesting.

All of the types of furnaces using the resistor ribbon can be operated either single-phase or polyphase and at practically unity power factor. The load installed on these types of furnaces varies from a few kw. up to around 500 kw. at the present time. However, this is not a maximum as any size installation is entirely practical from an engineering standpoint.

Induction furnaces run either single or polyphase. The type shown under this present development (Fig. 4) is a single-phase furnace having a capacity of 500 pounds per melt with 150 kv-a. installed. The power factor is between 60 and 70 per cent. These furnaces, although of lower power factor, give approximately the same load as a continuous resistance load.

The Weeks furnace operates single-phase and has for the 1/2-ton size a kw. rating of 200 and for the one-ton size 300 kw. The power factor averages around 80 per cent.

To the central stations, industrial electric heating is an extremely satisfactory load and consumes large amounts of power per customer. The load is practically continuous during the day time and in the majority of cases for twenty-four hours.

AJAX-WYATT ELECTRIC FURNACE

BY G. H. CLAMER
The Ajax Metal Co., Philadelphia.

The Ajax-Wyatt electric furnace is an induction furnace of the vertical ring type. An induction furnace is in reality merely a transformer with a single-turn secondary.

From the earliest days of the alternating-current transformer, it has been known that if such transformer were badly designed, namely, with insufficient core iron, or insufficient carrying capacity of the conductors, that losses would occur, due to the conversion of electrical energy into thermal energy.

Mr. Edwin A. Colby, of Newark, and Deferranti of England, each conceived the idea about the same time of so magnifying the heating effects in a transformer that an actual melting equipment resulted. To do this it was necessary to have a current path of sufficient resistance in proportion to the current flowing through it that actual melting, and superheating would take place. They accordingly constructed a transformer, on one leg of which was placed a primary coil, and a body of refractory material surrounded the opposite leg, in which was formed the channel, or groove, for containing liquid metal in the form of a single turn. In such a construction there was great magnetic leakage, hence, a low power factor.

Kjellin, a few years later, made a furnace of better transformer construction by placing his primary coil concentrically within the secondary coil, (the liquid metal bath). With this construction, having provided means for protecting the primary coil from the heat of the liquid metal, a much better power factor resulted. With this design of furnace, the power factor becomes relatively lower as the capacity of the furnace (size of ring) becomes greater. The Kjellin furnace was the first furnace of the induction type to meet with commercial success. Many patents and improvements have since been issued, such patents covering means for bettering the power factor, details of construction, and for two- or three-phase operation.

In Europe, the induction furnace is today largely in commercial use for steel melting, but in this country in such use it has met with very indifferent success due mainly to refractory troubles. Schneider, President of the Great Creusot Steel Works of France, and the Past President of the British Iron & Steel Institute, first conceived the idea of constructing a furnace with a closed channel of constant dimensions, and hence constant resistance, and having a bath above such column of liquid metal, thus providing a hydraulic head. He constructed a furnace in accordance with this idea, but after spending a considerable amount of money on it, was forced to abandon it because of the destruction of the refractory material surrounding the secondary loop.

In the Schneider furnace one end of the secondary loop was joined to the main bath at a higher level than the other end, the idea being to promote circulation due to the natural tendency of heated bodies to rise because of the difference in density. By incorrect proportioning of the secondary loop of metal slow circulation, due to thermal effect alone, would result. Because of slow circulation and the rapid conversion of electrical energy into thermal energy in the secondary loop, known as the resistor, the refractory materials would soon be brought to a temperature at which they fuse.

The next step in the development of the furnace I am about to describe, was the invention of Dr. Carl Hering. Dr. Hering found that it was possible to so proportion a liquid metal resistor, that when the current flowing through it was of high density, a force of considerable magnitude exerted itself upon the

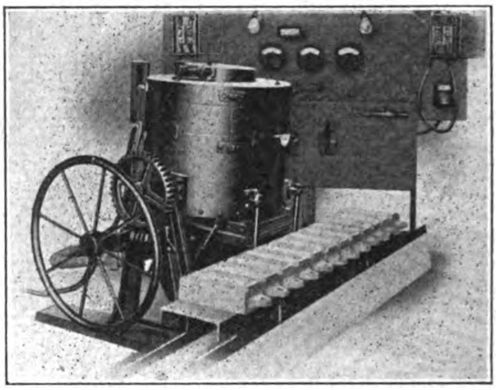

FIG. 1—AJAX-WYATT FURNACE

central section of such a column of liquid metal. By reason of this force, which he termed "pinch pressure," a rapid circulation would ensue, causing the liquid metal to be ejected from the center of the column and the cooler metal to flow into it at the periphery. By reason of the "pinch pressure" being exerted, the circulation becomes so rapid that overheating of the resistor walls does not result to nearly the same degree.

It is well-known that conductors in close proximity, and carrying current in the same direction, attract each other, whereas those carrying currents in the opposite direction repel each other.

Taking advantage of this phenomenon, Mr. James R. Wyatt added the further improvement of using this force, known as "motor effect," to circulate still more energetically the liquid metal in the resistor. By the very simple means of so constructing the resistor that it forms an acute angle, thereby causing the current to flow in opposite directions in the two legs of the triangle so formed, "motor effect" of considerable magnitude is set up at the angle. As the conductor (the liquid metal) is held in stationary walls the conductor cannot be bodily repelled, but the conductor being liquid is free to move and the metal is forced out of the resistor channel at the far sides, and

the cooler metal flows in to take its place on the inner sides of these channels.

The Wyatt furnace is a furnace in which the resistor is preferably placed in a vertical position and the main bath above the resistor. In the resistor rapid circulation ensues because of the combined forces exerted therein, namely, "motor effect," "pinch effect," and "thermal effect." Each of these forces tends to force the metal upward. The strongest force exerted is that due to "motor effect" which is applied in greatest degree of force at the angle, which is so placed that it is at the extreme bottom of the furnace.

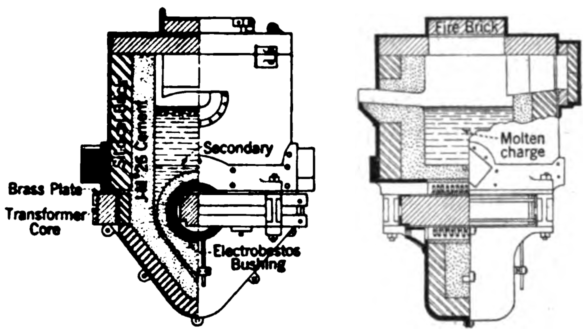

Fig. 2—Sectional Views of the Furnace

In such a furnace the heating and the stirring is all applied from the bottom (the logical place). No mechanical contrivance is necessary to produce circulation, or mixing. The conversion of electrical energy into thermal energy is 100 per cent, such transfer being accomplished in metal being heated. The heat losses are merely those due to radiation, and the small transformer losses.

The Ajax-Wyatt furnace has thus far been developed only for melting the copper-zinc alloys. It is possible to handle the full commercial range of such alloys as is used in rolling mill practise. Development work is progressing in adapting the furnace to other uses, and it is expected that it will shortly be possible to handle all the non-ferrous alloys in this furnace, and possibly some of the ferrous metals.

The characteristics of the Ajax-Wyatt furnace are the following:

1. Absolutely steady load.
2. Power factor—from 75 to 85 per cent, depending upon the size.
3. The metal is always the hottest part of the furnace.
4. No difficulty in getting required temperature for pouring.
5. Temperature under absolute control.
6. Thorough mixing without mechanical devices.
7. Due to shape of the hearth, or crucible, there is presented the smallest amount of exposed surface.
8. Lining cost per pound of metal melted, exceedingly small.
9. Requires minimum of attention.
10. The product of this furnace, because of the great uniformity and freedom from oxidation, is pronounced superior to that resulting from crucible, fuel-fired melting.
11. Efficiency on 60-kw. furnace, 11¼ pounds melted per kilowatt-hour. With 100 per cent efficiency the melting rate would be 12½ pounds per kilowatt-hour. Melting efficiency therefore 90 per cent. This seems almost unbelievable, but it is the day in and day out melting rate of the furnace covering period during which millions of pounds have been melted.
12. Metal losses—absolute minimum.

The drawbacks of this furnace are:

1. Lack of flexibility, by which is meant that it must be started with a liquid charge, and a portion of the charge must always be held in the furnace. This makes it difficult to change from one mixture to another, notwithstanding the fact that the electrical regulation provided is sufficient to take care of any of the copper alloys.
2. The furnace should always be kept heated by keeping a sufficient amount of current on the furnace to supply the heat losses.

Nine kw. is a little more than sufficient for this purpose on a 60-kw. furnace.

For intermittent operation, the leads may be plugged to low-voltage taps and the furnace sealed up after placing a layer of charcoal on the metal, and thereafter it requires no attention and is immediately ready for maximum melting efficiency when recharged

INTER-LABORATORY INSTRUMENT COMPARISONS

During the past month the Bureau of Standards has cooperated in a comparison of the standards of the various laboratories of one of the largest electrical manufacturing concerns in the country. This company has laboratories in a number of cities of the United States and a set of instruments for measuring electrical current, voltage, and power was carried from one to another of these laboratories, and to the Bureau of Standards. The instruments were carefully checked against the working standards of each laboratory. The results show a very gratifying agreement between the various plants and indicate that the standards in use by the electrical industry at large, so far as they are affected by this manufacturer, are satisfactorily uniform. The tests have also been of value in showing that the different types of instruments tested maintain their accuracy under various conditions of transportation.

Relative Advantages of Modern Steam and Electric Locomotives*

THE subject of the electrification of railroads was debated at a joint meeting of the New York sections of the American Institute of Electrical Engineers and the American Society of Mechanical Engineers, on October 22nd, in the Engineering Societies Building, New York. The interest taken in this subject was indicated by the size of the audience which filled all of the seats and all of the standing room in the auditorium. Mr. E. B. Katte presided in conjunction with Mr. H. W. Buck and Mr. W. S. Finlay, Jr.

F. J. SPRAGUE

President, Sprague Safety Control & Signal Corporation

Mr. Sprague, the first speaker, said that he wished to record his unchanging belief in the coming supremacy of electric power for transportation, and that his faith was based,—not upon a vast disparity between the best which can be built in a steam or electrical locomotive, nor upon any overwhelming claims of superior fuel economy when both are dependent upon coal supply, nor upon any material saving in operating expense sufficient to pay the charges incident to the increased capital cost when considered on existing traffic density and methods of operation,—but rather upon the broad ground of the overwhelmingly vital demand for *increased capacity*, a demand which ultimately can be met only by the electric system, because of characteristics individual to it.

Of course, there are inherent differences between the steam locomotive and its rival. The former is a moving power plant, limited both as to its maximum and its continuous rate of power development by the capacity of its boiler and portable fuel supply. It has, it may be granted, a certain apparent advantage because of its independent entity, but that very independence limits its capacity,—not materially in maximum traction effort,—for any locomotive can slip its wheels,— but in the amount of energy, that is, the product of speed and draw-bar pull, which is possible.

The electric locomotive, on the other hand, is but the user and transformer of electric energy created at distant power stations and transmitted to it by stationary conductors, and, thanks to the multiple-unit system any desired concentration or distribution of power units, under a common control, can be had, and any number of power plants, taking their energy from the centuries-old and diminishing supplies, or the annually renewed frozen white coal of the mountains, may be joined together in common supply.

And in that most difficult field of railroading, typified by the passage across the Great Divide, another and individual characteristic appears,—the power to make every train descending a grade act as a moving power plant to aid the others which are climbing it, as well as to provide a most effective braking mechanism.

But why the need of this great concentration of power, this possibility of increased unit-energy which is a function of speed? It is the demand,—insistent, threatening and vital—of increased capacity. Our modern life is dependent in a large measure upon two things, communication and transportation. The steam advocate will tell you that with regard to rail transportation its needs will be met by added trackage and augmentation of the power of his equipment. For the time being it will be, but how about the future?

There will come a time when duplication of tracks and increases in bridges, tunnels and terminals, and the power of individual units will reach practical limits, when physical facts will rebel against engineering dictum or operative demands, and then the way, and the only way, to meet the demand for increased capacity is by increase of speed, which can only be obtained when unlimited power is at the command of the operator.

Already the electrification of railway terminals is an essential; suburban service has long been in operation, and through operation of freight and passenger trains on mountain and other main line roads satisfactorily negotiated. The same kind of service which characterizes suburban operation can be as readily applied to the longer local runs, such as those between New York and Philadelphia.

As the demands increase, it will become more and more necessary to eliminate as far as possible non-essential rail transportation, and among such will be that coal which can be better burned at or near its source of supply and have its energy transmitted by wire.

Of course, the general electrification of trunk-line rialroads is not a matter of immediate possibility of accomplishment. It will only come as it is coming, progressively with the accelerating power of example. It will be governed very largely by financial conditions.

J. E. MULFIELD

Railway & Industrial Engineers, Inc.

Mr. Mulfield, the next speaker, said that, when we discuss or recommend the further electrification of the whole or any part of the 260,000 miles of steam-operated railroad system in the United States, which is now making use of about 65,000 steam and 375 electric locomotives for its passenger, freight and ter-

**Extracts from addresses delivered at the N. Y. Section meeting, October 22, 1920.*

minal service, the most important item involved is a correct and complete statement of facts, comparing the most up-to-date steam with similar electric operations, after which immediately come the important factors of the necessary financing and legislation.

While there is much existing steam road trackage that can and should receive first consideration as regards electrification for the purpose of eliminating gases from underground terminals and tunnels and to give relief to terminal or line traffic congestion in the vicinity of large commercial and industrial centers, it would be financial suicide to electrify immediately adjacent connecting and intermediate mileage, particularly in view of the improvements that can be made in both existing and new steam locomotives in the matter of reducing smoke, sparks, cinders and noise and in increasing general efficiency and economy in operation and maintenance.

With the decreased value of gold and purchasing power of the dollar has come an increase of from 4 and 5, to 7 and 8 per cent in the cost of money, which, in combination with the 100 to 150 per cent increase in the cost for labor and material makes the procurement today of the most pressing railroad capital needs almost prohibitive. Therefore, when engineers and politicians propose reckless superpower plans for the electrifying even of such belts of steam roads as lie in the densely populated district between Washington, D. C., and Boston, at a new capital cost approximating a billion of dollars, and in addition mark off the books the principal value of existing steam locomotives, passenger cars, shops, and terminal and intermediate facilities that would be unsuitable for the electrified service, they are planning either a new road to railroad bankruptcy, or a further burden in traveling and shipping costs, or in taxes, which would be representative of criminal waste instead of increased earning capacity by means of more efficient and economical operation.

Therefore, before the electric locomotive can be made permissible for general application the electrical engineer must reduce his first costs; promote interchangeability; provide a motor which will efficiently, economically and flexibly cover a wide range of speeds and not break down or deteriorate from overloading and heating; reduce complication, wear and corrosion in transmission and contact line apparatus; and substantially reduce the current losses between the point of power production and the locomotive draw-bar. Likewise the steam railway mechanical engineers, locomotive builders and specialty manufacturers, if they are to guard the steam locomotive and continue it in its present field of usefulness, must become more active in modernization and bring about improvement that will substantially increase its capacity and thermal efficiency by the use of higher steam pressures and superheat; compounding; more efficient methods of combustion; utilization of waste exhaust steam and products of combustion heat; better distribution and use of live steam; reduction of dynamic weights; greater percentage of adhesive to total weight and a lower factor of adhesion; and by a substantial reduction in standby.

The immediate requirements of new money for the more urgent steam equipment and facilities needed to provide adequate, safe and expeditious rather than luxurious service in the regeneration of the railroads, is the obvious reason for the continued utilization of the over-all more economical steam operation, and only after the possibilities in this direction have been realized can any serious financial consideration be given to the proposed radical change to super-electrification.

F. H. SHEPARD

Director of Heavy Traction, Westinghouse Electric & Mfg. Co.

Mr. Shepard stated that the demand for traffic movement will undoubtedly be doubled in about 12 years; so the question arises as to how we are going to handle it. The limit to physical expansion of railroad line and of terminals has been just about reached in many cases, on account of both the prohibitive cost and the inefficiency of terminals of unworkable size. A large measure of relief can still be secured by line and terminal revisions and improvements, but when the inevitable increase in the demand for traffic movement of the future is considered, these improvements savor, more or less, of expedients to secure relief which can only be temporary and very limited in degree.

The yearly average of 22 miles per day for a freight car for the whole country, with monthly averages of as low as five miles on some of our most congested railroads for a single month, emphasizes the fact that this is a problem that some how, some way, we must solve. The solution lies, to a large extent, in railroad electrification.

With the present standards of train make-up, classification and terminal handling, electrification will double the capacity of any railroad. With the better equipment we can expect in the future, together with the evolution of improved methods of operation contingent on electric power, this capacity should be doubled again, thus securing four times the present capacity. This should certainly be accepted as a vision of the future, and why not our aim? Unless some broad and consistent program is embraced, the situation, which is serious indeed today, may well be calamitous tomorrow.

The electric locomotive has generally, thus far, been a mere substitute for the steam locomotive, although, in some cases, due to the greater power of the electric locomotives, there has been a modification of the handling of traffic.

The advantage of electric power is its great flexibility and mobility. The difference between locomotives, steam and electric, is fundamental. The steam

locomotive carries its own power plant, while the electric locomotive, on the other hand, is simply a transformer of power. The design of the steam locomotive is circumscribed utterly by the necessity of tying up the rest of the machine to the steam boiler. On the other hand, the electric locomotive assembly can differ amazingly as to type, length, axle loading and driving connections. A group of small motors does not differ materially from a single large motor in efficiency. The speed and power, therefore, of an electric locomotive is limited only by conditions of track and construction and condition of car equipment. It thus becomes entirely practicable to build an electric locomotive to take any train which will hold together, over any profile whatever, and at any desired speed. Therefore, it should easily be practical to very greatly increase the speed of our freight trains so that they could all run at a common speed not very different from that at which the superior trains are operated.

A. H. ARMSTRONG

Chairman Electrification Committee, General Electric Co.

Mr. Armstrong presented a number of tables showing comparative figures for steam and electrical operation, covering relative economy of fuel, hauling capacity, maintenance charges and general flexibility.

A comparison of the modern steam and electric locomotive leads immediately to a discussion of the relative fitness of the two types of motive power to meet service conditions. At present, railway practise has closely followed steam engine development, but are we not justified in looking at the transportation problem from the broader standpoint of a more powerful and adaptable type of motive power?

Place at the disposal of an experienced train dispatcher a locomotive capable of hauling any train weight that modern or improved draft gear can stand, at any speed permitted by track alignment regardless of ruling grade or climatic conditions, that can be run continuously for a thousand miles with no attention but that of the several operating crews, and witness what he can accomplish in his all important task of expediting freight movement. It is not merely a question of replacing a Mikado or Mallet by an electric locomotive of equal capacity. The economies thus effected are in many instances not sufficient in themselves to justify a material increase in capital account. The paramount need of our railways today is improved service and this can be brought about by introducing the more powerful, flexible and efficient electric locomotive. Marked changes in present railway practise will undoubtedly follow the adoption of a type of motive power that is free from many of the limitations of the steam engine.

From the comparative performance data given, the author summarized the principal advantages of electric traction as follows:

1. No structural limits restricting tractive effort and speed of electric locomotive than can be handled by one operator.

2. Practical elimination of ruling grades by reason of the enormously powerful electric locomotives available.

3. Reduction of down-grade dangers by using regenerative electric braking.

4. Very large reduction in cost of locomotive maintenance.

5. Very large saving of fuel, estimated as two thirds the total now burned on steam engines in operation.

6. Conservation of our natural resources by utilizing water power where available.

7. Material reduction in engine and train crew expense by reason of higher speeds and greater hauling capacity.

8. Increased valuation of terminal real estate following electrification.

9. Increased reliability of operation.

10. Material reduction in operating expense due to elimination of steam engine tenders and most of the company coal movement, the two together expressed in ton-miles approximating nearly 20 per cent of present gross revenue ton mileage.

11. Large reduction in effect of climatic conditions upon train operation.

12. Postponement of immediate necessity for constructing additional tracks on congested divisions.

13. Attractive return on cost of electrification by reason of direct and indirect operating savings effected.

14. Far-reaching improvements in operation that may revolutionize present methods of steam railroading.

H. B. GATELY

Chief Engineer, Locomotive Superheater Co.

Mr. Gately claimed that the data submitted by the advocates of electric traction have been far from satisfying to the men who are obliged to decide the question of steam or electricity for traction. There has been great lack of publicity with respect to the total investment, and the return on the investment, in electric operation of trains.

It is futile to discuss fuel per drawbar horse power, or maintenance cost per hundred engine miles, without some idea of what the return on the capital investment will be. The engineering public, as a rule, has no conception of what it has cost the railway company for the various electrified divisions about which so much has been said. It is hoped that some data on this point will be forth-coming tonight.

Mr. Muhlfeld has concisely pointed out the economic problem confronting the railroads. To electrify existing steam-operated roads is at present more nearly impossible in a financial sense than ever before. Reference to the financial pages of newspapers and magazines in the last six months will confirm the statement that the soundest and best railway organizations have had to pay 7 per cent, and upwards, for money needed to maintain their properties. Roads in a less secure financial position are unable to obtain funds, even at these high rates. Unless it can be conclusively

proved that the return on the investment, all factors being considered, is better than with steam operation, the electrification of our main lines, and the extension of present terminal electrifications may, as has been said, be the electrical spelling of catastrophe.

It may be well to consider the unusual position in which the railroad systems of the country now find themselves. Embarrassed and restricted by years of repressive legislation, which often prevented the carrying out of constructive programs planned to safeguard future operation, then forced to undergo the trying and critical experience of government control, they are now facing a reconstruction period which must make up for a three year's hiatus in maintenance and replacements. This must be done almost at once.

It is further to be noted that in a great many of the public utterances and published articles, dealing with main line electrification, and in which reference to, and comparison with, the steam locomotive has been made, the conditions of comparison equitable then are not fairly representative for the present day. These comparisons have too frequently been made between almost obsolete saturated steam locomotives, on the one hand, and the new and thoroughly up-to-date electric locomotives on the other. It is only fair to insist that comparison be made with the modern superheated steam locomotive.

F. J. COLE

Chie Consulting Engineer, American Locomotive Co.

Mr. Cole stated that in all the papers and reports of the electrical installations, we find much about the advantages and much of what has been accomplished, but we search in vain for a complete financial statement showing at what cost in dollars and cents all this is accomplished. Many electrical installations are necessary for special needs such as are mentioned elsewhere, but it has yet to be proved that there is any great demand for the wholesale electrification of railroads in this country.

From the rusty rails and grass-grown tracks of many ill-considered electrical suburban lines running through sparsely settled districts, which do not earn sufficient rates on the investment to warrant a decent upkeep, we can obtain some appreciation of what would result from electrification of railroads if pushed beyond its natural limitations at the present time.

From the standpoint of cost, the question of steam versus electric operation in one which all the factors which make up the respective costs of different installations have to be considered. Thus, in the case of electricity, the entire cost of changing over from steam operation must be taken into account. This includes many items, the cost of which is difficult to obtain and is not usually published, such as, power houses, overhead or third rail construction, change in methods of signaling, shops, tools and appliances necessary for the maintenance of electrical equipment. For electrification it is customary to supply power station capacity in boilers, engines, turbines and generating apparatus largely in excess of the normal demand, located in more than one station so that there may be no interruptions in the supply of current. Two power stations were supplied in the case of the New York Central Terminal, each of which I believe was sufficient to supply power, if necessary, to the entire electric zone. This is, no doubt, very desirable and proper, but it must be included when the cost of electrification is considered. Presumably railroads are now in possession of the necessary appliances for steam operation, and electrification means that much of such equipment must be diverted into other channels, or discarded, so that in figuring the total operating and capital charges for electrification it is necessary to keep these items well in mind.

The electrification of terminals, tunnels and certain mountain divisions where water power is available, are now recognized as desirable installations. Among such are the Grand Central Terminal and the Pennsylvania entrance in New York City, the Baltimore & Ohio tunnel through Baltimore, the Hoosac Tunnel, the Cascade Division of the C., M. & S. P., and perhaps the Norfolk & Western, Elkhorn Grade. Some of these are absolutely necessary, regardless of cost.

Then, too, there may be a few zones in this country which by reason of density of traffic and coordination with the electrified terminals could probably be changed from steam to electric power with profit and quicker dispatch of business.

The reports of electrifications do not give costs of installation, how much was spent in changing over from steam to electricity, or what interest is paid for the money so expended, so that costs of future electrification *can* be accurately forecast. *This* is the question which should be answered—Is it cheaper to operate by steam or by electricity, and can freight per ton mile be moved at less cost (when all expenditures are considered) by electricity than by steam?

The details should not be featured to the exclusion of the whole installation. There are, admittedly, many attractive characteristics of electric power, but when it comes to a *wholesale* replacement of steam locomotives, especially on roads not peculiarly adapted to electrification, those responsible for the financial returns to the owners and to the public, may well hesitate and ask to be shown the cost, not only of the installation under consideration, but of those now in operation, and the probable return on the investment for the large expenditure they are asked to approve.

DISCUSSION

The discussions were by C. H. Quin, Chief Electrical Engineer, Norfolk & Western Railroad; A. W. Gibbs, Chief Mechanical Engineer, Pennsylvania Railroad System; W. L. Bean, Assistant Mechanical Superintendent, New York, New Haven & Hartford Railroad; F. H. Hardin, Chief Engineer of Motive Power, New

York Central Railroad; R. Beeuwkes, Electrical Engineer, Chicago, Milwaukee & St. Paul Railroad, and W. F. Kiesel, Jr., Mechanical Engineer, Pennsylvania Railroad.

The closure to the discussion was by Mr. George Gibbs, Consulting Engineer, Pennsylvania Railroad, who said in part:

I cannot go into technical details tonight, but I think our electrical friends will concede, and mechanical men must, in light of sufficient evidence furnished by existing installations, that an electric system will function in a successful, reliable and efficient manner for any kind of railway service. It is capable of unlimited hauling capacity, is flexible as to speed and has important features conducing to safety in handling trains. It is however, to the fundamental question affecting its adoption which I wish to draw attention; "Is the substitution of electric for steam haulage warranted by its advantages in the production of more transportation, and if so, is it practicable financially?" No sweeping generalization to the effect that electric traction will be used because it functions well will impress railway managers; they must have the answer to the above question.

Now, as regards the first portion of this query, it would appear that there are a number of important situations in which electric traction will produce results which cannot be had by the steam locomotive, notably in increasing existing track capacity, especially on lines having heavy grades, in hard shifting, in suburban and terminal services, and in location (such as in tunnels) where the absence of combustion is necessary or desirable. Such installations should be undertaken if financially feasible, and this can only be determined by a critical examination of each case. Assuming that the money can be raised for an improvement which will pay, it will be found that electric traction will pay, directly or indirectly, in the special cases to an extent depending upon the density of traffic and the difficulty of maintaining proper steam operation. It must be admitted that an electric installation involves a higher first cost than for steam, in fact, its adoption means that more or less existing investment must be scrapped, therefore, the increased in fixed charges must be offset either by the direct operating savings produced or these plus the indirect savings and benefits. The latter may mean avoidance of permanent way additions, a permissible change in operating methods, more traffic moved, and new kinds of traffic produced. The direct savings have been under discussion tonight; in spite of some difference in opinion, I think we cannot escape the conclusion that there is always a large saving in fuel with electric traction, generally some saving in maintenance cost of "power equipment" and often important savings in train crew costs, engine house expenses, minor supplies, etc.

Sometimes these "direct" savings will be sufficient to return a handsome profit over and above charges; if not, the indirect savings must be included. It will avoid future disappointment if we face the facts; the electrification of the railways of the country as a whole, or the electrification of the whole of any extensive component system, is neither practicable nor desirable, measured by costs and results; the doom of the steam locomotive has not been sounded and will not be in our time. But the fact that electrification is not universally applicable should not discourage anyone; it has a very large and profitable field (both for the railways and the manufacturers). These facts indicate the importance of carefully investigating each proposed application to insure that it is properly conceived and carried out.

ATHLETIC FIELD TO COMMEMORATE EMPLOYEE HEROES

The Western Electric Company is rushing the construction of a ten acre athletic field at its Hawthorne factory near Chicago to commemorate its 61 employees who sacrificed their lives during the war. It is believed that when completed this field will be one of the largest memorials in this country.

It is interesting in view of this memorial to note the report the Company has just circulated regarding the war activities of its personnel. 7,521 of its employees were actively engaged in some type of service during the period of hostilities. Of this number, 4,675 were in the army, and 1,253 entered the navy.

Because of their intimate familiarity with the various means of communication, the Western Electric employees had an exceptionally large representation in the Signal Corps; 609 members of its technical organization saw service with the telegraph battalions the field signal battalions and the telephone operator units. Infantry and artillery organizations also proved exceptionally popular drawing 1,721 and 824 men respectively.

The members of the big electrical concern were well represented among the commissioned and non-commissioned ranks of their respective branches of the service. The army personnel boasted 5 lieutenant-colonels, 8 majors, 28 captains, 68 first lieutenants, 116 second lieutenants and 683 non-commissioned officers. Of this aggregation 983 are known to have won promotion during the period they wore khaki; 2,299 of the company's men saw service over seas.

A present estimate of the casualties among those who entered the service shows that 52 soldiers were killed and 121 were wounded. The navy losses included 9 killed and 12 wounded.

Development on Radio Generators for the Army and Navy

BY F. I. HISS

Manager Small Motor Dept., Crocker-Wheeler Co., Ampere, N. J.

THIS article records an interesting war development of small machines of very special design carried out by the writer in 1917 for the Signal Corps and for the Bureau of Steam Navigation.

The company with which the writer is associated, as its share in war work was almost entirely engaged in the manufacture of motor generators, etc., for wireless service for the Government.

In the fall of 1917 the Crocker-Wheeler Co. was asked by the Signal Corps to develop a wind-driven generator, in cooperation with the Western Electric Co., which would be suitable to supply the energy to operate their radio telephone which was to be part of the standard equipment of the army airplanes.

In the PROCEEDINGS of March last year Messrs. Craft and Colpits describe the development of the whole telephone equipment; and in an article in the *Electric Journal* of May, 1919, Mr. H. M. Stoller, of the Western Electric Co., describes the operation of this generator and the method of control which he developed. He points out that the development of these machines proved to be a considerable problem in itself, as it was necessary to secure constant voltage over a range of speed from 4000 to 12,000 rev. per min., which corresponds to an airplane speed range of from 60 to 120 miles per hour. In addition to all of the ordinary requirements for power equipment there was the additional requirement of furnishing current free from commutator ripples and brush noise. The regulation was accomplished by means of special generator design and the use of an audion valve.

This generator is illustrated in these papers; and in the same issue of the *Electric Journal* is illustrated a similar design manufactured by another company, of which the Signal Corps asked assistance in view of very large production anticipated; but this generator, the writer believes, was still in the experimental stage when the armistice halted operations.

DESCRIPTION OF THE GENERATOR

The standard generator was to furnish approximately 70 watts at 25 volts and 50 watts at 275-300 volts for energizing the audion of the radio set, the use of batteries being almost out of the question due to the high voltage required and other obvious considerations.* The generator was driven by an air propeller and was mounted as found most convenient on the plane, generally strapped to one of the plane struts.

The machine was to be completely enclosed so that it could be exposed to the weather with impunity and was to offer as little air resistance as possible. Fig. 1 shows the machine with enclosing covers in place, and Fig. 2 another view with air propeller attached.

Fig. 3 shows the machine as finally developed with front and rear stream line covers removed and with the tube regulator and mounting, which parts were

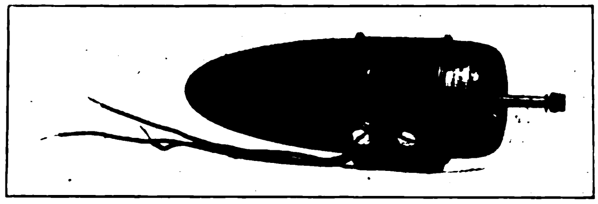

FIG. 1

supplied to the generator manufacturer by the manufacturers of the radio set. Aluminum parts were used wherever possible in order to cut down the weight to a minimum, and the stream line covers were aluminum spinnings $^1/_{16}$ in. thick.

The development of the first sample was completed early in 1918 and the machine put into commercial production shortly after, and at the signing of the armistice the production had been raised to about 200

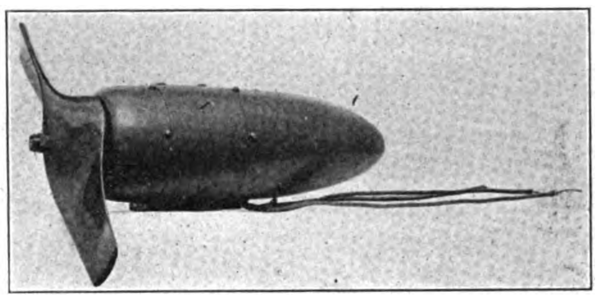

FIG. 2

machines per week, a total of between 2000 and 3000 machines having been delivered at that date some of which were put into service in France.

Fig. 4 shows a group of machines after test ready for shipment and after sealing by the U. S. Signal Corps inspector, at the plant at Ampere, N. J.

*It is interesting to compare the British practise during the war. In a paper by Major C. E. Prince in the *Journal of the Institution of Electrical Engineers* of May 1920, he mentions that originally they used dry batteries for the high-tension circuit and storage batteries for the low-tension. One of the first telephone sets without batteries weighed only 10 lb. while the high-tension batteries alone weighed 36 lb.

Later he mentions they adopted a wind-driven generator which supplied high and low-tension voltage with a storage battery floating across the low-tension side.

Again he mentions that there seems good reason to hope that in the near future a perfectly silenced and well balanced generator will permit the abolition of the battery, all current being supplied from the generator. He is apparently unaware of work which was accomplished in the development of this generator for the U. S. Signal Corps.

Development of the Generator

It was realized when the first sample was built that the main problem would be to build an armature which was sufficiently well balanced to operate smoothly at the maximum speed of 12,000 revolutions and which could be produced in large numbers on a commercial scale. With this end in view it was decided to attempt to build an armature which would

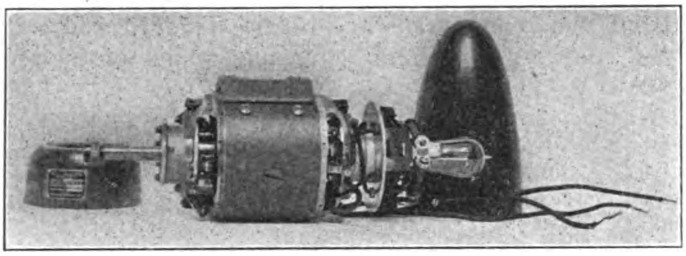

Fig. 3

be well balanced by virtue of design and accurate manufacture of its parts and not have to resort to static or dynamic balancing; and ultimately this end was completely obtained.

Though every machine delivered was tested and had to give steady voltage up to 12,000 rev. per min., not one of these armatures was given either a static or dynamic balance.

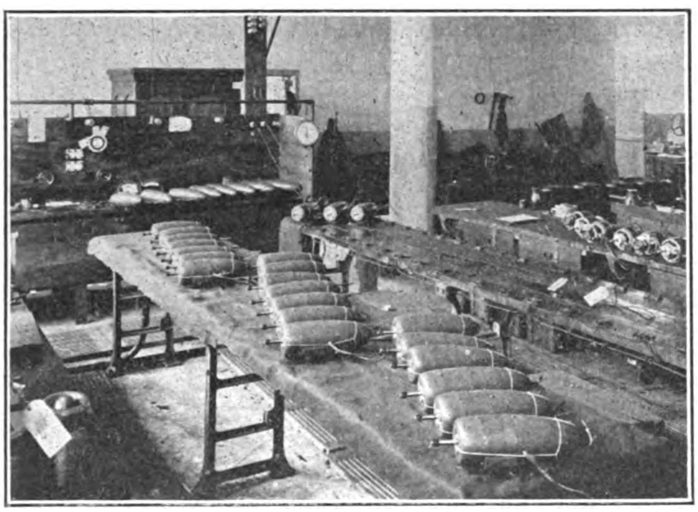

Fig. 4

Commutation was perfect up to 8000 rev. per min., and at this speed there was very slight vibration.

When the maximum operating speed of 12,000 rev. per min. was reached there was slight sparking but not an extent to cause injury either to brushes or commutator or excessive brush noise in the telephone. Further, each machine was given an overspeed test for one minute at 14,000 revolutions.

The remarkable running qualities of these armatures (see Fig. 5) were obtained in part by the following means:

1. Armature diameter was reduced to a minimum, that is 2 ½ in. over all.
2. A very large shaft was used having a ¾ in. diameter in the core.
3. Armature punchings were given the rather heavy press fit on the shaft of 0.004 in.

Ball bearings of the double-race type were adopted, but some trouble was experienced with the commercial bearing used, as it was found that the inner race of the bearing was not absolutely concentric, and vibration with resulting bad commutation was experienced due to the slight eccentricity of the inner race; but when this trouble was discovered and the manufacturers approached they went to endless trouble to correct it, with the result that the eccentricity of the inner race was held down to 0.0005 in. in all cases.

The commutators were designed and built with great care and only one case occurred of commutator destruction, this being due to a cracked steel flange,

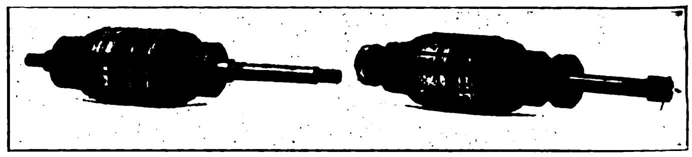

Fig. 5

one of the commutators bursting on the overspeed test.

The next problem was to provide a well balanced armature winding, and after very careful consideration it was decided to wind the high-tension winding of fine wire (No. 34 gage) by machine in the bottom of the slots, drawing each wire as tight as possible, and then to put a hand-wound low-tension winding over this to protect the fine wires of the high-tension winding.

After a good deal of practise this method of winding was worked out. The armature core was placed bodily in the cheeks of an armature winding machine and the high-tension winding put in, connected to the high-tension commutator, and the whole carefully insulated.

The low-tension winding was then wound in by hand. The result was that the high-tension winding was never disturbed or put under strain in any way during the process of winding, and the low-tension hand winding served to protect the high-tension winding like a tightly woven basket; and to this can be attributed the fact that the armatures showed no tendency after long periods of running to develop open circuits, due to breakage of the fine high-tension wire. In the early experimental type of this generator much trouble had been experienced, and was only eliminated when this method of winding was devised.

After the low-tension winding had been put in and connected the end windings were carefully protected

by a wrapping of seine twine. The armature was dipped and baked in Sterling varnish three times. Treatment with heavier compounds or impregnating the armature was tried, but was found unsuccessful as the absorption of large quantities of heavy compound in the winding tended to throw the armature out of balance.

Great attention was paid to the design of the brush gear of these generators. It was found that duplex

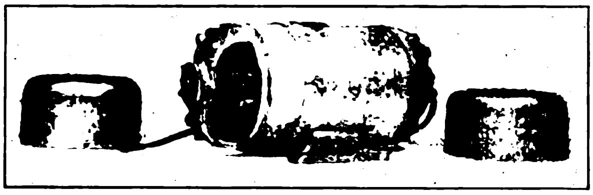

Fig. 6—Dynamotor Open

brushes under heavy radial spring pressure, the inertia of the brush being reduced to a minimum, gave as would be expected, the best results.

The very high brush pressure of approximately 15 lb. per square inch was used initially so as to guarantee a pressure of seven or eight lb. per square inch when the brush had worn.

On account of the intense vibration to which the machine was subjected every nut and screw used in any part was effectively locked, so that under no conditions could anything work loose.

1500-Volt Dynamotor

The devlopment of another interesting type of machine was undertaken and accomplished on very short notice for the Bureau of Steam Navigation for operating the wireless telegraph on Navy seaplanes.

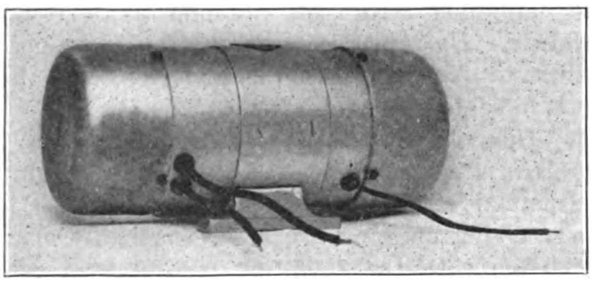

Fig. 7—Dynamotor Closed

Specifications called for a dynamotor with an output of 450 watts at 1500 volts, these dynamotors taking current from a 24-volt storage battery. A 1500-volt machine of this size was decidedly a novelty at the time and the department asked that 50 of these be designed and delivered in three months.

Some experimental work had been done in preparation for such a demand in the early days of the war and as the result of this experience the writer felt confident that a satisfactory operating machine could be built with one armature winding as against the obvious plan of winding two separate 750-volt armatures and putting them in series.

At the start it was realized that there would be no difficulty in maintaining insulation to ground for such voltage but that the difficulty would be to produce an armature winding which would not short-circuit between turns and which would not open-circuit due to the necessary use of very fine wire, subjected to extreme vibration.

Form-wound coils were discarded at the start as being unsuitable for such work due to the fact the wire would be put under strain when the coil was forced into the slots, and break connection with the commutator after a few hour's service.

On the other hand it was realized that if the winding were wound in by machine in the customary manner that large differences of potential would exist at all cross-over points at the ends of the winding and also would occur between adjacent sections of the winding in the slots.

The high-tension winding of these armatures was therefore completely sectionalized, that is, the turns between the adjacent commutator bars were completely insulated both at the ends and in the slots from each adjoining section. The maximum voltage existing between any part of this armature winding except where ample insulation was provided, did not exceed about 50

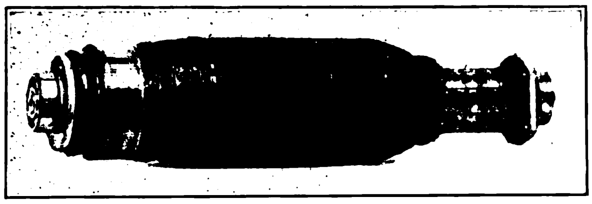

Fig. 8—Dynamotor Armature

volts, equal to the voltage between adjacent commutator bars.

It was also felt that no effort should be spared to get the best possible insulation on the wire itself, so the writer approached the Acme Wire Company with the suggestion that it might be able to manufacture a special insulated wire in No. 34 B. & S. gage, which was the size required for these armatures. In view of the importance of the work this concern immediately offered all its special resources, and as a result in about two or three weeks it was able to produce a wire following the author's suggestions which showed great improvement in dielectric strength of its covering.

A double-silk-covered enamel wire was run through the enameling machine, and in this way the silk was saturated and given an enamel coating, on the outside of the silk covering. Next this wire was run through the silk-covering machine, and an extra covering of silk put on, and finally this triple-silk-covered wire was again run through the enameling machine and an insulated wire produced, which was very superior to any commercial magnet wire obtainable and was found very suitable for the purpose of winding these high-voltage armatures.

After the high-tension winding had been wound in by machine, and completely insulated, the low-tension winding was wound over it by hand, protecting the high-tension winding very effectually against the effect of centrifugal forces.

Abstractive and Selective Properties of Radio Antenna Circuits

BY EDWARD BENNETT
Professor of Electrical Engineering, University of Wisconsin

(*Continued from page* 1004 *of JOURNAL for November, 1920*)

13. *The maximum power which an antenna can abstract from sustained waves and deliver to a detector.* To make the delivery of power from sustained waves to the detector associated with a *given* antenna a maximum, the equivalent resistance of the detector, R_d, should be made equal to the sum of the radiation resistance, R_r, plus the wasteful resistance R_w, of the antenna. Let us assume that the detector is so proportioned, and that the ratio of the resistance is as expressed in equations (**1**) and (**2**).

If an antenna has an extended capacity area at a height (h) and is resonant to the sustained impinging waves, the average power, P, delivered to the detector after the current attains the steady-state value, is

$$P = \frac{(E_{r.m.s.})^2}{4\,k\,R_r} = \frac{(h\,F_{r.m.s.})^2}{4\,k\,R_r} = \frac{(h\,F_m)^2}{8\,k\,R_r}$$

in which, F_m represents the peak value of the electric intensity of the impinging waves.

Substituting in the above equation, the expression for the radiation resistance of an extended flat top antenna, namely

$$R_r = \frac{4\,\pi\,h^2}{3\,s\,p_0\,\lambda^2}$$

the expression for the power becomes,

$$P = \frac{3\,s\,p_0\,\lambda^2\,F_m^2}{32\,\pi\,k} \qquad (17)$$

Since the dimensions of the flat top antenna do not appear in this equation, it follows that the power which can be delivered (after the oscillation has built up to the steady-state value) to a detector is independent of the height and area of the antenna network, *except in so far as the height and area may affect the value of k.* Throughout this discussion, it is assumed that the greatest dimension of the antenna is a small fractional part of the wave length.

It is of interest to put the above expression for the maximum power in a form fraught with greater physical significance.

$$P = \frac{3}{16\,\pi\,k}\,(s\,\lambda^2)\left(\frac{1}{2}\,p_0\,F_m^2\right) \qquad (18)$$

Now $\left(\frac{1}{2}\,p_0\,F_m^2\right)$ represents the energy in the dielectric per cubic cm. when the peak of the electromagnetic wave impinges upon the antenna, (s) represents the velocity of propagation, and (λ^2) represents the area of a square whose side is equal to the wave length,—*a wave length square.* Since the electric intensity F is a sine function of time, the average value of $\left(\frac{1}{2}\,p_0\,F^2\right)$ taken over the wave as it streams past the receiving station is 1/2 of $\left(\frac{1}{2}\,p_0\,F_m^2,\right)$ and since the electro-kinetic energy $\left(\frac{1}{2}\,\mu_0\,H^2\right)$ is equal to the electro-potential energy $\left(\frac{1}{2}\,p_0\,F^2\right)$, it follows that $(s\,\lambda^2)\left(\frac{1}{2}\,p_0\,F_m^2\right)$ represents the energy which streams past the receiving station per second across an area equal to the wave-length square. That is to say, the greatest average power which can be delivered to a detector by an antenna from impinging sustained waves equals $\left(\frac{3}{16\,\pi\,k}\right)$ times the power flowing across a *wave-length square* at the receiving station.

The above conclusion does not hold if the radiation resistance is partially neutralized by associating a power amplifier with the antenna as a *resistance neutralizer. By resistance neutralization* it is possible to abstract from the impinging waves more power than is indicated by equation (**18**).

14. *Directive Efficiency of a Radio System, and Abstractive Factor of an Antenna Circuit.* For the hypothetical case in which the wasteful resistances of a receiving antenna are made negligibly small in comparison with the radiation resistance, k reduces to unity, and the power which can be abstracted from impinging waves and delivered to a detector depends only upon the frequency at which the radio transmission system is operated, varying inversely as the square of the frequency. That is, for this hypothetical case, the amount of power which the antenna can deliver to the detector is inherent in the operating frequency of the *system* of radio transmission and in the distance between the sending and receiving stations. The suggestion is therefore made that the *directive efficiency of the system* be defined as the ratio of the power which would be delivered to the detector in this hypothetical case to the total power which would stream across the hemisphere on which

the receiving antenna is located if there were no refraction or absorption losses in transmission.

Since the power which would be delivered to the detector with no wasteful antenna resistance, is,—

$$P = \frac{3}{16\pi} s \lambda^2 \left(\frac{1}{2} p_0 F_m^2\right) \tag{19}$$

and since the power which would stream across the entire hemisphere (on the supposition of no transmission loss or refraction) is,

$$P_1 = \frac{4\pi r^2}{3} s \left(\frac{1}{2} p_0 F_m^2\right) \tag{20}$$

in which, r represents the distance between sending and receiving stations, it follows that the directive efficiency D_e of the system is,

$$D_e = \frac{9\lambda^2}{64\pi^2 r^2} \tag{21}$$

The directive effciency of a system of radio transmission varies directly as the square of the wave length, and inversely as the square of the distance between the stations.

In the actual antenna, in which the wasteful resistance is not zero but in which the sum of the wasteful plus the radiation resistance is (k) times the radiation resistance, the power delivered to the detector is $(1/k)$th of the hypothetical maximum expressed by equation (**19**). It is therefore suggested that $(1/k)$ be termed the *abstractive factor of the antenna circuit* A_f.

$$A_f = 1/k \tag{22}$$

At the higher frequencies (200,000 cycles and higher) an abstractive factor of 50 per cent at a time constant of 0.01 second can be obtained with an antenna of small volume and consequently of low cost. At the lower frequencies (60,000 cycles and lower) an abstractive factor of the order of ten per cent with a time constant of 0.01 second can be obtained only by building a costly antenna of enormous volume. The abstractive factor of many antennas (particularly coil antennas) is extremely low,—less than 0.001 of one per cent.

It should be noted that the abstractive factor, as defined above, can be made to exceed 100 per cent at the higher frequencies by resorting to *resistance neutralization.*

15. *The combination of frequency with antenna height and area which will lead to a high selective coefficient against "strays."* In the present state of the art, the interference with radio communication caused by "strays"—atmospheric or cosmic electromagnetic disturbances—is more serious than the interference resulting from other stations.

We proceed to consider the nature of these disturbances, to define what we mean by the selective coefficient of an antenna against disturbances of this type, and finally to determine the effect of the synchronous frequency and the dimensions of the antenna upon this selective coefficient.

There is no direct experimental evidence as to the wave form of the electromotive forces induced in the antenna by strays. The electromotive forces will, however, fall under one of the four forms shown in Fig. 8.

These four forms of stray electromotive forces are:

A. A continuous e. m. f. sustained for several natural oscillations of the antenna, as shown at (A) Fig. 8.

B. An impulse electromotive force, as shown at (B).

C. A rapidly damped oscillation of lower frequency than the antenna, as shown at (C).

D. A rapidly damped oscillation of higher frequency than the antenna, as shown at (D).

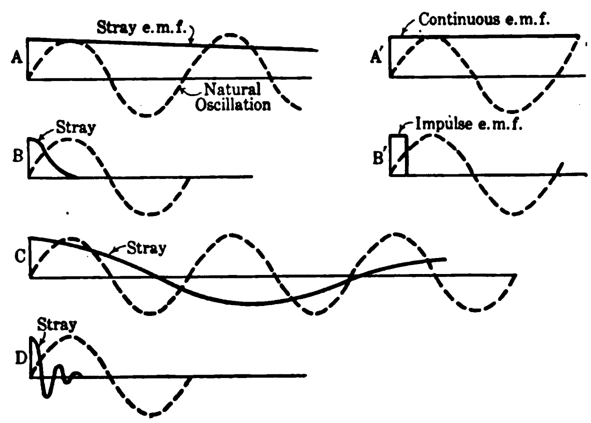

Fig. 8

In my estimation the heaviest lightning discharges are substantially dead beat discharges which induce in the antenna an electromotive force of the form shown at (A); or it is possible that they may be of the form (C) with a decrement greater than .5. In the case of those lightning discharges which are observed to be of great length (or of low frequency), while the radiation resistance alone would be sufficient to cause a decrement of the order of only .1, I would expect the wasteful resistance to greatly exceed the radiation resistance and to make the discharge deadbeat.

Some experimental evidence has been obtained in the study of lightning disturbances on transmission lines that small local discharges, which result in a redistribution of charge between neighboring portions of the atmosphere, may take place. Such discharges may be expected to induce in the antenna an impulse voltage of form (B).

The properties of an antenna to rapidly damped alternating e. m. fs. of the forms (C) and (D) may be inferred from the properties to sustained voltages of the form (A) and to impulse voltages of the form (B). For our purpose, then, there are interferent electromotive forces of only three types to be considered; namely:

(1) Sustained alternating e.m.fs. (already discussed).
(2) Sustained continuous e. m. fs. of form (A).
(3) Impulse e. m. fs. of the form (B).

We may feel assured that if those antenna proportions are determined which result in the highest selective coefficient to these three types, then these proportions will be the best for the intermediate forms. In order to make types 2 and 3 easy to treat, we assume that the wave form of the stray e. m. fs. is as shown at A' and B' in Fig. 8.

The term selective coefficient with a modifying prefix has already been defined for two sets of conditions. The *steady-state selective coefficient* of a receiving circuit against a specific detuned frequency has been defined as the ratio between the power delivered to the detector by sustained waves of a frequency such as to make the circuit resonant and the power delivered to the same detector by waves of the same intensity but of the specified detuned frequency: the power being determined after the current builds up to the steady-state value. The *selective coefficient for the time interval* T_e (the Morse dot interval) against a specified detuned frequency is defined as the ratio between the energy delivered to the detector by an impressed alternating electromotive force of a frequency such as to make the circuit resonant and the energy delivered to the same detector by an electromotive force of the same value but of the detuned frequency,—both electromotive forces being impressed for the same interval of time T_e.

The *selective coefficients for the time interval* T_e of a receiving circuit against a continuous electromotive force of the form A' (Fig. 8) or against an impulse electromotive force of the form B' will be defined as the ratios of the energy delivered to the detector by an impressed alternating electromotive force of a frequency such as to make the circuit resonant and the energy delivered to the same detector by the continuous electromotive force or by the impulse electromotive force, respectively; the peak or maximum values of all three electromotive forces are to be the same, and the alternating electromotive forces is to be impressed for the time interval T_e. (The impulse electromotive force will, of course, be impressed for the impulse interval only). The interval T_e will be the Morse dot interval with some methods of receiving, and the beat interval with others.

TABLE VI

RELATIONS BETWEEN THE DIMENSIONS OF AN ANTENNA AND THE ENERGY EXPENDED IN THE DETECTOR BY AN IMPRESSED CONTINUOUS ELECTROMOTIVE FORCE.

NOTE: $R_d = R_w + R_r = k\,R_r$

1	Form of antenna	Parallel plate	Elevated disk	Vertical wire	Square loop
2	Induced voltage peak (E)	$h\,F$	$h\,F$	$h/2\,F$	$\frac{2\pi N h^2 F}{\lambda}$
3	Capacity, approximately (C)	$\frac{p_0\,a}{h}$	$8\,p_0\sqrt{a/\pi}$	$\frac{2\pi p_0 h}{\log h/r}$	$\frac{p_0\,\lambda^2}{16\pi^2 N^2 h}$
4	Stored energy ($1/2\,C\,E^2$)	$1/2\,p_0\,a\,h\,F^2$	$4\,p_0\sqrt{a/\pi}\,h^2\,F^2$	$\frac{\pi p_0 h^3 F^2}{4\log h/r}$	$\frac{p_0 h^3 F^2}{8}$
5	Initial current peak ($2\pi f\,C\,E$)	$2\pi f\,p_0\,a\,F$	$16\sqrt{\pi a}\,f\,p_0\,h\,F$	$\frac{2\pi^2 f p_0 h^2 F}{\log h/r}$	$\frac{h\,F}{480\pi N}$
6	Radiation resistance (R_r)	$\frac{4\pi f^2 h^2}{3 s^3 p_0}$	$\frac{4\pi f^2 h^2}{3 s^3 p_0}$	$\frac{\pi f^2 h^2}{3 s^3 p_0}$	$\frac{64000}{243\pi s p_0}\left(\frac{h f}{s}\right)^4 N^2$
7	Initial power expenditure in detector	$\frac{8\pi^3 s p_0 k a^2 h^2 F^2}{3\lambda^4}$	$\frac{512\pi^2 s p_0 k a h^4 F^2}{3\lambda^4}$	$\frac{2\pi^5 s p_0 k h^6 F^2}{3\lambda^4(\log h/r)^2}$	$\frac{2000\,s\,p_0\,k\,h^6\,F^2}{243\pi\lambda^4}$
8	Relations between dimensions, frequency, and time constant	$a\,h = \frac{3 s^3}{16 k\pi^3 T_c f^4}$	$a^{\frac{1}{2}} h^2 = \frac{3 s^3}{128 k \pi^{5/2} T_c f^4}$	$h^3/\log h/r = \frac{3 s^3}{8\pi^4 k T_c f^4}$	$h^3 = \frac{243\pi s^3}{16000\,k\,T_c\,f^4}$
9	Stored energy, in terms of frequency and time constant	$\frac{3 p_0 s^3 F^2}{32 k\pi^3 T_c f^4}$	<———	<———	$\frac{3 p_0 s^3 F^2}{16 k\pi^3 T_c f^4}$
10	Energy from resonant freq. to detector in interval T_e	$\frac{3 b T_e F^2 s^3 p_0}{32\pi k f^2}$	<———	<———	$\frac{30 b T_e F^2 s^3 p_0}{163\pi k f^2}$
11	Selective coefficient for interval T_e	$2\pi^2 b\,T_e\,T_c f^2$	<———	<———	<———
12	Initial power expenditure in detector in terms of freq. and time constant	$\frac{3 p_0 s^3 F^2}{32 k\pi^3 T_c^2 f^4}$	<———	<———	$\frac{40 p_0 s^3 F^2}{163 k\pi^3 T_c^2 f^4}$
13	Selective coefficient against first cycle	$\pi^2 b\,T_c^2 f^2$	<———	<———	<———

16. *The effect of the antenna dimensions upon the energy expended in the detector by a sustained continuous electromotive force.* The relation between the antenna dimensions and the energy expended in the detector by a sustained continuous electromotive force may be rapidly determined by making use of the well known relation that when a continuous electromotive force is suddenly impressed in a circuit containing a condenser, the energy expended is equal to the energy eventually stored in the condenser.

Antennas divide into the four forms listed in Table V.

TABLE V

FORMS OF ANTENNAS

Parrallel Plate Antennas: Antennas having a capacity area of such great extent as compared with the mounting height

that the capacity of the antenna is inversely proportional to the height, the capacity being given approximately by, $C = \frac{p_o\, a}{h}$

Disk Antennas: Antennas having the extended capacity area mounted so high that the capacity is approximately independent of the height—being approximately equal to

$$8\, p_o \sqrt{\frac{a}{\pi}}$$

Vertical Wire Antennas: A single vertical wire, the capacity of which is approximately proportional to the height; the capacity being expressed approximately by the relation

$$C = \frac{2\,\pi\, p_o\, h}{\log h/r}$$

Coil or Loop Antennas: If the dimensions of the coil are so small in comparison with the wave length that the distributed capacity may be neglected, the inductance of a single turn square loop antenna having a side length (h) which is 1000 times as great as the radius of the wire is expressed approximately by the relation

$$L = 4\,\mu_o\, h$$

Table VI shows the relations between the dimensions of antennas of these four forms and the energy expended in the detectors associated with the antennas. In arriving at these relations, it has been assumed that in each case the greatest dimension of the antenna is small in comparison with the wave length corresponding to the resonant frequency of the loaded antenna.

Referring to Table VI. Line 2 gives the induced electromotive force in terms of the electric intensity F. F represents the sustained e. m. f. induced per centimeter of height of the flat top antenna by the impinging disturbance. (It is to be noted that throughout this paper, the calculations are based upon the hypothetical case of a wave front perpendicular to the surface of the earth). For the vertical wire antenna, the net value of the induced voltage is $F\,h/2$.

Line 4 shows the energy which will be stored in the condensors whose capacities are given in Line 3 under impressed electromotive forces of the values shown in Line 2. An equal amount of energy is dissipated in the resistances during the charging process, and of this dissipated energy one-half is expended in the detector. From this line it will be seen that the energy delivered to the detector by a sustained continuous "stray" electromotive force increases directly as the ($a\,h$) product (or as the volume under the antenna) in the case of the parallel plate condenser, and almost as the cube of height in the case of the vertical wire and loop antennas.

From Line 7 it will be seen, however, that the *initial rate* at which energy is delivered to the detector (or the power expenditure in the detector during the first oscillation caused by the stray) increases directly as the *square* of the volume under the parallel plate antenna, and almost as the *sixth power* of the height of the vertical wire and loop antennas. The initial power expenditure in the detector equals $1/2\,(I_p)^2\,k\,R_r$, in which I_p represents the initial peak value of the charging current. The values of the initial current peak as given by the relation

$$I_p = 2\,\pi\, f\, C\, E$$

are written in Line 5.

In order to obtain a small amount of energy from the stray, the antenna dimensions must be small. But in the attempt to reduce the interference from strays, the dimensions of the antenna should not be reduced below the point at which the time constant of the antenna has increased to .01 second. The relations between the antenna dimensions and the time constant have been written in Line 8. On substituting the expression for the dimensions from Line 8 in the expressions for the stored energy as given in Line 4, the expressions for the stored energy which appear in Line 9 are obtained. From this line it is seen that the energy obtained from the continuous e. m. f. varies inversely with the length of the time constant, and inversely as the fourth power of the resonant frequency. On the other hand, the energy obtained in the time interval T_e from impinging waves of resonant frequency varies inversely as the square of the frequency. The expressions for the energy delivered to the detector in the time interval T_e by an alternating e. m. f. of resonant frequency, having a peak value equal to the value of the continuous e. m. f., are written in Line 10, in which the value of the factor b depends only upon the length of the time interval T_e as compared with the length of the time constant T_c. If T_e is a Morse dot interval, .05 second, and T_c = .01 second, b equals 0.8. The values of b may be read from Curve E of Fig. 6.

The selective coefficient of each antenna for the time interval T_e will be found by dividing the expressions for the energy from the resonant e. m. f. appearing in Line 10 by the expressions for one half the energy from the continuous e. m. f. which appear in Line 9. The result of this division is written in Line 11. The selective coefficient for the interval T_e against a sustained continuous stray electromotive force is seen to vary directly with the length of the time constant of the circuit and directly with the square of the resonant frequency.

$$S_c \text{ (against a continuous e. m. f.)} = 2\,\pi^2\, b\, T_e\, T_c\, f_r^2 \qquad (23)$$

Line 12 contains expressions for the initial rate at which energy is expended by the continuous e. m. f. in the detector. The rate is written in terms of the resonant frequency and the time constant of the circuit. These expressions have been obtained as the result of the elimination of the antenna dimensions from the Line 7 expressions for the initial power by means of the relations given in Line 8.

Line 13 is the result of dividing the expressions for the energy from the resonant frequency which appear in Line 10 by the time interval T_e and then by the

expressions from Line 12 for the initial power expenditure. Line 13 represents the ratio of the average rate at which energy is delivered to the detector by the resonant electromotive force to the initial rate at which the continuous electromotive force delivers energy to the detector. These ratios may be designated as the *selective coefficient against the first cycle.*

$$S_c \text{ (against first cycle)} = \pi^2\, b\, T_c^2 f_r^2 \quad \textbf{(24)}$$

17. *Effect of the antenna dimensions upon the energy delivered to the detector by an impulse electromotive force.* The relative amounts of energy delivered by a given impulse electromotive force to two *highly oscillatory* antennas tuned to different frequencies depends greatly upon the length of the impulse relative to the natural periods of the two antennas. Thus, if the impulse lasts for an interval equal to 1/4 of the natural period of an antenna, the energy delivered to the antenna is approximately $C\,E^2$; if it lasts for 1/2 the period, the energy is $2\,C\,E^2$; if it lasts 3/4 of the period, the energy is $C\,E^2$; and if it lasts for an interval equal to the period, the energy delivered is approximately zero. Of course under these conditions it is difficult to draw conclusions as to the best antenna proportions for impulse strays lasting for varied and unknown time intervals. There are, however, two cases which may be discussed to advantage.

For the case of two different impulse strays of the same electric intensity impinging upon two different antennas and each lasting for an interval such as 1/4 or 1/2 or 3/4 of the natural period of the antenna upon which it impinges, the conclusions which have been drawn above with reference to the selective coefficient against a sustained continuous electromotive force may be applied.

This follows from the fact that the energy delivered to the detector by the sustained continuous electromotive force is $1/4\ C\,E^2$ (assuming $R_d = R_w + R_r$), while the energy delivered to the antenna by the impulse electromotive force is some multiple of this. Of the energy delivered to the antenna by the impulse stray, one half will be delivered to the detector and the other half will be dissipated as the oscillation of the antenna dies out. Therefore the following conclusion may be drawn. The selective coefficient of antenna circuits of high resonant frequency and of long time constant against those impulse strays which persist long enough to deliver to the antenna the maximum possible energy is much greater than the selective coefficients of circuits of low frequency or of short time constant.

The second simple case is the case in which a given impulse "stray" impinges upon antennas tuned to different frequencies, and in which the natural periods of both antennas are ten or more times as long as the time interval (T_1) of the impulse. In this case the energy delivered to the antennas is given approximately by the expression

$$W = 1/2\,C\,E^2\,4\,\pi^2 f_r^2\,T_1^2 \quad \textbf{(25)}$$

If we substitute in this expression the values of $1/2\,C\,E^2$ as given in Table VI for the four classes of antennas, we arrive at the following expression for the selective coefficient against impulse voltages of very short duration

S_c against impulse voltages of very short duration

$$= \frac{b\,T_e\,T_c}{2\,T_1^2} \quad \textbf{(26)}$$

in which,

T_e is the Morse dot interval

T_1 is the length of the voltage impulse

T_c is the circuit time constant, and

b is a factor whose value depends upon the relative length of T_e and T_c, approaching unity as T_e/T_c becomes greater and greater. (The values of b may be taken from Curve E of Fig. 6).

This expression shows that the selective coefficient against such an impulse varies directly as the length of the time constant of the circuit.

The expression is independent of the resonant frequency of the circuit, and this is apt to be misleading. It must be borne in mind that this expression applies only to an impulse which lasts for a short decimal part of the natural period of the antenna. If we compare the effect of two impulses, each of which lasts for the same *decimal part* of the natural period of the antenna in which the impulse is impressed instead of for the same interval of time, this expression likewise shows that the selective coefficient varies directly as the square of the natural frequency, because T_1 now varies inversely as the frequency.

From an inspection of the expressions for the selective coefficients, namely, equations 7, 23, 24, and 26, the following conclusions may be drawn. The selective coefficient of an antenna whether against a sustained alternating electromotive force which is detuned by a given *percentage* of the resonant frequency, or against a continuous "stray" electromotive force, or against an impulse voltage which lasts for a given small decimal part of the natural period of the circuit, varies directly as the square of the resonant frequency of the antenna. Against a sustained detuned alternating e. m. f., the selective coefficient varies directly as the square of the time constant of the antenna. Against continuous and impulse voltages, the selective coefficient apparently varies directly as the first power of the time constant, but if in different circuits the time constant is always made equal to 0.02 of the interval of excitation, the selective coefficient in reality varies directly as the square of the time constant, or as the square of the interval of excitation. (See equations 13 and 14.)

18. *Effect of the unavoidable departures from resonance upon the power received.* In the determination of the selective coefficients in the preceding pages,

the receiving circuit has been assumed to be resonant to the correspondent station. In the every day operation of two stations it is, of course, impracticable to keep the receiving station exactly resonant to the sending station, because of slight unavoidable variations in the sending frequency and in the constants of the receiving circuit. If the receiving circuit is not exactly resonant to the impinging waves, the power received from the correspondent station is reduced, and the selective coefficient against the interferent source is thereby decreased. A high selective coefficient is obtained by making the time constant of the circuit long, or by making the circuit highly oscillatory, but it is evident that after a circuit has been made so highly oscillatory that the unavoidable departure from the condition of resonance gives rise to a net or residual reactance which is greater than the circuit resistance, then practically nothing is to be gained by making the circuit more highly oscillatory. Any further decrease in the circuit resistance will reduce the power received from the interferent and correspondent sources at substantially the same rate.

This question arises: Is it practicable to hold the frequency of the sending station constant enough, or to keep the receiving station tuned closely enough, to attain as high a selective coefficient as the other requirements will permit? In answering this let us assume, somewhat arbitrarily, that the permissible detuning is such as to make the net reactance $(X_L - X_c)$ equal to the resistance of the receiving circuit. Under these conditions the impedance to the correspondent frequency will be $\sqrt{2}$ times the circuit resistance, the power received from the correspondent station will be one-half as great as at exact resonance, and the selective coefficients against interferent sources will be one-half as large as at exact resonance. If the detuning is 1/2 as great as above assumed, the power received from the correspondent station is cut down to 0.8 of the power at exact resonance, while if the detuning is twice as great as assumed, the power is cut down to 1/5 of the power at exact resonance.

If the frequency is P_d decimal parts high or low, the inductive reactance X_L is P_d parts higher than the resonant value, and the capacity reactance X_c is P_d parts lower than the resonant value, or vice versa, and the net reactance is,

$$X_L - X_c = 2\, P_d\, X_L$$

Under the assumption made above, the permissible detuning is such that

$$(X_L - X_c) \text{ or } 2\, P_d\, X_L = R$$

$$\text{or} \quad 4\, \pi\, f_r\, L\, P_d = R$$

$$\text{but} \quad T_c = \frac{2\, L}{R}$$

Eliminating L and R between the above equations, the permissible detuning P_d is,

$$P_d = \frac{1}{2\, \pi\, f_r\, T_c} \text{ parts} \tag{27}$$

$$= \frac{1}{2\, \pi\, T_c} \text{ cycles} \tag{27a}$$

That is, the permissible detuning if expressed in decimal parts (or in per cent) is inversely proportional to the resonant frequency and to the time constant of the circuit, and if expressed in cycles is inversely proportional to the time constant. We have seen that a time constant of 0.01 second is desirable. Substituting this value in equation (**27**), the permissible detuning in a circuit having a time constant of 0.01 seconds is found to be 15.9 cycles per second. No matter what the resonant frequency may be, the permissible detuning (as herein defined) in a circuit having a time constant of 0.01 second is 15.9 cycles per second. Now a detuning of 15.9 cycles per second means a permissible detuning of 0.1 of one per cent at a resonant frequency of 15,000 cycles, but of only 0.003 of one per cent at 500,000 cycles. While circuits may be held in tune as closely as 0.1 of one per cent, it is questionable whether it will be found feasible to hold a sending and receiving station as closely in tune as 0.003 of one per cent.

The conclusion to be drawn is that the impracticability of keeping the receiving and sending stations closely enough in tune will establish a limit above which it is not feasible to increase the selective coefficient of the receiving circuit.

19. *Conclusions relating to the plain series antenna for receiving purposes.* The desirable features of a radio communicating system are summarized below in the order of the more complex relations first. The conclusions pertain mainly to the properties of the plain receiving antenna.

Item 1. A radio communication system may be divided into three parts,

The receiving station
The transmission medium
The sending station

Item 2. The desirable features of the receiving antenna in itself are,

a. A high selective coefficient against interferent sources: that is, the ratio of the power or energy received from the correspondent station to the power or energy received from the interferent source should be as high as possible.

b. High directive efficiency: that is, the ratio of the power which could be abstracted by a receiving antenna with negligible wasteful resistance to the power streaming across the hemisphere on which the receiving antenna is located should be as high as possible. The "directive efficiency" is directly proportional to the square of the wave length.

c. High abstractive factor: that is, the ratio of power abstracted by the actual antenna to the power

which could be abstracted by the hypothetical antenna of zero wasteful resistance, should be as high as possible. The abstractive factor equals $1/k$.

Item 3. The desirable feature in the transmission in itself is high transmission efficiency: that is, the ratio of the power streaming across the hemisphere upon which the receiving antenna is located to the power radiated from the sending station should be as large as possible. This ratio will be called the "transmission efficiency."

Item 4. The desirable feature in the sending station in itself is that the cost of radiating power per kw-hr. shall be low.

Conclusions Relating to the Selective Coefficient

Item 5. The expression for the steady state selective coefficient in terms of the dimension of the antenna is,

$$S_c = \frac{9\, p_d^2\, S^6}{64\, k^2\, \pi^4\, a^2\, h^2\, f_r^6} \tag{5}$$

This expression would indicate that to obtain a high selective coefficient, the operating frequency should be low and the dimensions of the antenna small. While this conclusion would be correct for a radio power transmission system, operating with an uninterrupted flow of power, it is grossly erroneous for a make and break communication system. In a dot and dash communicating system it is not permissible to decrease the dimensions and the frequency indefinitely, because with this decrease the time constant of the circuit increases, and a condition may very readily be reached in which the time constant of the circuit far exceeds the Morse dot interval. Under this condition, the current at the resonant frequency has only time to build up to a small fractional part of the full or steady-state value, and the above equation fails to correctly express the *Morse-dot-interval-selective-coefficient*. Accordingly, the conclusions drawn from equation (5) should be discarded and the selective coefficient should be expressed in terms of the resonant frequency and the time constant as in the following item.

Item 6. The expressions for the selective coefficients in terms of the resonant frequency and the time constant of the antenna are as follows:

S_c for steady-state against a detuned frequency

$$= (2\, \pi\, f_r\, p_d\, T_c)^2 \tag{7}$$

S_c for interval of excitation against a detuned frequency

$$= 0.8\, (2\, \pi\, f_r\, p_d\, T_c)^2 \text{ if } T_c = .2\, T_e \tag{13}$$

S_c against a continuous e. m. f.

$$= 2\, \pi^2\, b\, T_e\, f_r^2\, T_c \tag{23}$$

S_c for first cycle against a continuous e. m.f.

$$= \pi^2\, b\, T_c^2\, f_r^2 \tag{24}$$

S_c against a very short impulse

$$= \frac{b\, T_e\, T_c}{2\, T_1^2} \tag{26}$$

These equations indicate that to obtain a high selective coefficient the resonant frequency should be high and the time constant of the antenna as long as possible, subject to the limitations cited below in Items 7, 9, 10.

The selective coefficient cannot be materially increased by making the time constant longer than the interval of excitation. The longest time constant permissible in sustained wave reception equals 0.2 of the interval of excitation.

Item 7. To provide for intervals of silence between the dots and dashes, the time constant of the antenna should not exceed 0.2 of the Morse space interval, or at a sending speed of thirty words per minute the time constant should not exceed 0.01 second.

Item 8. In so far as the resistance of the tuning inductance is concerned, it is feasible to make the time constant of the receiving antenna as long as .01 second.

Item 9. The relation between the time constant and the frequency and dimensions of the antenna is given in equation (6)

$$T_c = \frac{3\, s^3}{16\, \pi^3\, k\, a\, h\, f_r^4} \tag{6}$$

To obtain a long time constant requires the use of a low resonant frequency or of an antenna of small dimensions and of relatively low wasteful resistance. To obtain a time constant as long as .01 second, or longer, there is no difficulty whatsoever: it is only necessary to make the antenna small enough. Moreover the smaller the antenna dimensions, the easier it is to make the wasteful resistances negligibly small, or to make (k) approach the value for 100 per cent abstractive factor, namely 1.

On the other hand, to build a receiving antenna having a natural time constant *as short as* .01 *second* at the lower frequencies—30,000 cycles or less,—is quite costly, although such an antenna is comparatively inexpensive for the higher frequencies,—120,000 cycles or higher. For illustrations of the sizes see Tables III and IX. At 30,000 cycles the Darien antenna has a time constant of .0042 sec. if $k = 2$. That is, its height cannot be reduced to less than .0042/.01 or 42 per cent of its present height without increasing its time constant beyond .01 sec. At 120,000 cycles the 10 meter antenna having 5 per cent of the area of the Darien equivalent antenna has a time constant of .0047 second. For a time constant of .01 sec. this ten meter antenna needs to have an area of only 2.5 per cent of the Darien equivalent, or a radius of only 36 meters.

The conclusion is that an antenna with a time constant as short as .01 second is very expensive for the lower frequencies.

Item 10. The impracticability of holding the sending frequency and the natural frequency of the receiving antenna constant enough establishes a limit above which it is not feasible to increase the selective coefficient by increasing the time constant and the frequency.

The permissible detuning, which has been arbitrarily taken as the detuning which will cut down the correspondent power to one-half of the full resonant value, may be computed by the equation

$$P_d = \frac{1}{2\,\pi\,f_r\,T_e}\text{ parts} \tag{27}$$

$$P_d = \frac{1}{2\,\pi\,T_e}\text{ cycles} \tag{27a}$$

The permissible detuning if expressed in cycles per second is independent of the resonant frequency at which the system is operated, and depends only upon the time constant of the antenna. If the time constant is 0.01 second, the permissible detuning is 15.9 cycles per second. At a frequency of 120,000 cycles per second, this is a detuning of only 0.013 of one per cent. This value (0.00013) may tentatively be accepted as a limit below which it is not feasible to hold the detuning of the correspondent station. Table VII is a brief tabulation of the conditions which tend to set the limits for the time constant of the receiving antenna.

Conclusions as to the Directive Efficiency of the System of Transmission

Item 11. The greatest power that the antenna can deliver to the detector is $\left(\frac{3}{16\,\pi\,k}\right)$ (approximately 0.06, if $k = 1$) of the power streaming across a "wave-length" square of the hemisphere on which the receiving antenna is located, unless resistance neutralization is resorted to.

The directive efficiency of the system of radio transmission varies inversely as the square of the resonant frequency. From the point of view of directive efficiency, the operating or resonant frequency should be low.

$$\text{Power to (detector)} = \frac{3}{16\,\pi\,k}\,(s\,\lambda^2)\,(\tfrac{1}{2}\,p_o\,F_m^2) \tag{18}$$

$$D_e = \frac{9\,\lambda^2}{64\,\pi^2\,r^2}$$

Conclusions as to the Power Abstractive Factor of the Antenna

Item 12. The power abstractive factor of the antenna is the ratio of the energy delivered to the detector to the energy which might have been delivered to the detector if the wasteful resistance R_w were zero, and the detector resistance R_d were equal to the radiation resistance R_r. If, as in the discussion, the detector resistance is made equal to $(R_w + R_r)$, and if the ratio of $(R_w + R_r)$ to R_r is designated by k, the abstractive factor is $1/k$. At the higher frequencies abstractive factors of fifty per cent may be obtained. The abstractive factors will necessarily be lower at the very low frequencies. Very low abstractive factors may be warranted at the lower frequencies because of the fact that the selective coefficient may be made to have the same value at the low abstractive factor as at the high factor. (See Item 15).

$$A_f = 1/k \tag{22}$$

Conclusions Relating to the Transmission Efficiency

Item 13. The only available information relating to the absorption losses in transmission, or to the transmission efficiency, is embodied in Austin's formula; namely, the power P streaming across unit area near

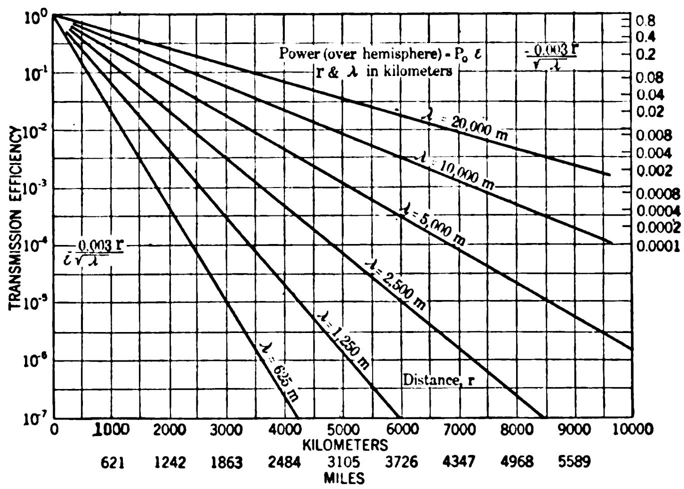

Fig. 9—Relation Between Transmission Efficiency and Distance

the ground at the distance r from the sending station is

$$P = P_0\,\epsilon^{\frac{-0.003r}{\sqrt{\lambda}}} \tag{28}$$

in which P_0 is the power which would stream across unit area near the ground were there no transmission losses and no refraction, and r and λ are expressed in km.

From this the transmission efficiency (T_r) is

$$T_r = \epsilon^{\frac{-0.003r}{\sqrt{\lambda}}} \tag{29}$$

This formula should be used with many reservations, because it is based upon meager data of a kind which it is extremely difficult to gather and to interpret.

The transmission efficiencies for different wave lengths and distances of transmission have been plotted in Fig. 9. These curves bring out the gre merit of the lower frequencies for the longer trans-

mission distances. For example, in a 6000 km. (3726 mile) transmission, the transmission efficiency for a wave length of 10,000 meters (30,000 cycles) is $3.4\ 10^{-3}$, while for a wave length of 1250 meters (240,000 cycles) the transmission efficiency is only 10^{-7}.

Conclusions Relating to the Cost of Power Radiated from the Sending Station

Item 14. With the developments which are still taking place in methods of generating high frequencies, it cannot be determined whether it will eventually be cheaper *to deliver to the antenna* power at the higher or at the lower frequencies.

TABLE VII
CONDITIONS WHICH TEND TO SET THE LIMITS FOR THE TIME CONSTANT OF THE CIRCUIT.

Tending to set a limit to the length of T_c	Tending to set a limit to the shortness of T_c
To provide for intervals of silence between the dots, the time constant cannot be allowed to exceed 0.2 of the Morse space interval, that is, cannot exceed 0.1 sec. at 30 words per minute.	The selective coefficient varies directly as the second power of the time constant, therefore the time constant should be long.
The impracticability of holding the sending and receiving stations more closely tuned than P_d = .00013 decimal parts, makes it of no advantage to make T_c larger than given by $\frac{1}{2\pi f_r T_c} = .00013$	The volume under the antenna (the $a\,h$ product) necessary to reduce the time constant to .01 sec. varies inversely as the time constant and the fourth power of the frequency. To obtain a short time constant at the low frequencies requires an enormous antenna.

TABLE VIII
MERITS OF HIGH VERSUS LOW FREQUENCIES

Merits of high	Merits of low
High frequency leads to a high selective coefficient S_c varies as f_r^2	The directive efficiency varies inversely as the square of the frequency D_e varies as $\frac{1}{f_r^2}$
The higher the frequency, the smaller may the volume of the receiving antenna be without causing the time constant to exceed .01 second. $a\,h = \frac{3\,S^3}{16\,\pi^3\,k\,T_c\,f_r^4}$	The permissible detuning, in decimal parts, is greater at the lower frequencies. $P_d = \frac{1}{2\,\pi\,f_r\,T_c}$
The abstractive factor may be made somewhat higher at the higher frequencies.	The transmission efficiency for long distances is far higher at the lower frequencies than at the higher.
The cost of radiating power per kw. is far lower at the higher frequencies. $P = \frac{2\,\pi^2\,a^2\,f_r^4\,E^2}{45\,s^4}$	

However, the charge per kw. for radiating power *from* the antenna which is entailed by the cost of the antenna itself is far higher at the lower frequencies than at the higher. This follows from the fact that the power which can be radiated from an antenna of given dimensions *at a given voltage* varies as the fourth power of the frequency. Putting the matter in another way, to radiate a definite amount of power from an extended platform antenna at a given voltage, the area of the platform must be inversely proportional to the square of the frequency. For example: With the key tied down the Darien antenna at 100 r. m. s. kv. will radiate 3,080 kw. at 120,000 cycles, but only 12 kw. at 30,000 cycles. Herein is low frequency at a disadvantage.

Conclusions Relating to the Figures of Merit of the Frequencies When Receiving With Plain Antenna Circuits

Item 15. In Table VIII the merits of high versus low frequencies are tabulated.

In Table IX is a compilation of data relating to the merits of the different frequencies for different distances of transmission. In the first and second lines of this table are tabulated the frequencies and wave lengths to which the following data pertains.

In line 3 is given the radius which an extended circular platform antenna must have in order to radiate 5 kw. at 100 r. m. s. kv. with the key held down continuously.

In line 4 is given the height at which an upper network of the radius specified in line 3 must be mounted in order that the time constant shall be 0.01 second, assuming that $k = 2$, or that the total resistance is equal to four times the radiation resistance of the network. If the height is made greater, the time constant will be shortened, T_c varies as $1/h$. In the sending station, there is no reason why the time constant should not be shorter than 0.01 second. However, increasing the height will not permit of any reduction in the radius of the sending network if 5 kw. is to be radiated at 100 kv., unless the height is of the same order as or greater than the radius of the network. In the receiving station there is no reason why the radius should be as large as given in line 3. All that is required is that the $(a\,h)$ product shall have the same value as for lines 3 and 4. At the higher frequencies, the antenna of both the sending and receiving stations would be much smaller in radius and higher than the figures given in lines 3 and 4.

In line 5 is given in decimal parts the permissible detuning between the correspondent stations: that is, the detuning which will, when the receiving circuit has a time constant of 0.01 second, cause the correspondent power to drop off to fifty per cent of the full resonant value. The close tuning required at 480,000 and 240,000 cycles may be unattainable. If these values are unattainable, the selective coefficients given

in lines 6 and 7 for the two higher frequencies are also unattainable, and should not be greater than the selective coefficient for 120,000 cycles.

In line 6 is given the selective coefficient against sustained continuous voltage strays of the same electric and magnetic intensity as the correspondent waves.

In line 7 is given the selective coefficient to sustained waves detuned by one per cent. As previously noted under line 5, the high selective coefficients for 240,000 and 480,000 cycles are unattainable unless the resonant frequency of the sending and receiving circuits can be held as close as specified in line 5.

Hence if we are concerned only with the absolute amount of power received from the correspondent station, the continued product
(transmission efficiency) × (directive efficiency) × (abstractive factor)
may be characterized as the "Figure of Merit of the frequency for power transmission purposes with antenna costs neglected." Under these conditions the comparison between the frequencies reduces to this: The merits of the low frequency are the higher transmission and higher directive efficiencies: its demerits are, the greater volumes of the antennas which must be used at both the sending and receiving

TABLE IX
FIGURES OF MERIT OF THE FREQUENCIES WHEN RECEIVING WITH PLAIN ANTENNA CIRCUITS: ANTENNA COSTS ARE NEGLECTED.

1	Frequency		480,000	240,000	120,000	60,000	30,000	15,000
2	Wave length ... meters		625	1250	2500	5000	10,000	20,000
3	Radius for radiating 5 kw. at 100 r. m. s. kv. ... meters		11.5	23.	46.	92.	184.	368.
4	Height for a T_c of .01 sec. with above radius ($k = 2$) meters		.36	1.44	5.76	23.	92.	368.
5	Permissible detuning in decimal parts if $T_c = .01$ second		.00003	.000065	.00013	.00026	.00052	.001
6	Selective coefficient against continuous voltages		1024 ( )	256 ( )	64 ( )	16 ( )	4 ( )	1 (1.810[6])
7	Selective coefficient against alternating e.m.f.s detuned by 1 %		1024 ( )	256 ( )	64 ( )	16 ( )	4 ( )	1 (89)
8	Abstractive factor		.5	.5				
9	Directive efficiency r in km		1/1024 ( )	1/256 ( )	1/64 ( )	1/16 ( )	1/4 ( )	$\left(\frac{5.7}{r^2}\right)$
10		500 km.	.15	.28	.40	.50	.60	.70
11	Transmission efficiency	1000 km.	.02	.07	.15	.28	.40	.50
12	(No great reliance should be placed on these	2000 km.	.0005	.005	.02	.07	.15	.28
13	transmission efficiencies)	4000 km.		.00002	.0005	.005	.02	.07
14		8000 km.			.0000003	.0002	.0005	.005

In line 8, the abstractive factor has been listed for the higher frequencies only, as approximately fifty per cent. It will be much lower at the lower frequencies.

In line 9 is given the directive efficiency of the receiving antennas.

In lines 10 to 14 is given the transmission efficiency of the different frequencies for different transmission distances from 500 to 8000 km.

If two sending stations are each radiating the same amount of power but at different frequencies, and each station is sending to its own receiving station, located, say, 4000 km. away, the ratio between the power inputs to the two receiving stations is the ratio between the values of the following continued products for each system.
Power input = (Power radiated) × (transmission efficiency) × (directive efficiency) × (abstractive factor)

stations and the somewhat lower abstracting and radiating efficiencies even with antennas of the larger volume.

In a radio communication system the item of importance is not the absolute amount of power received from the correspondent station, but the relative amounts of power received from the correspondent station and from the interferent sources. Again assume that two sending stations are each radiating the same amount of power but at different frequencies, and each station is sending to its own receiving station, located, say, 4000 km. away. The power per unit area streaming past each receiving station is proportional to the transmission efficiency for the particular frequency. That is to say, the square of the electric intensity at each antenna or the square of the voltage induced per unit length in the antennas of each receiving station, is proportional to the transmission efficiency for the frequency. Whereas the electric

intensity set up by the interferent sources must be taken to be the same at one station as at the other. Hence it follows that if the *selective coefficients of the two receiving antennas had the same numerical value* the ratio between the power ratios of the two receiving stations would be proportional to the transmission efficiencies.

$$\frac{\text{Correspondent power for freq. 1}}{\text{Interferent power for freq. 1}} : \frac{\text{Correspondent power for freq. 2}}{\text{Interferent power for freq. 2}} -$$

= Transmission efficiency for freq. 1 : Transmission effic'y. for freq. 2,

But for each receiving station the ratio between the correspondent and interferent power abstracted from waves of the *same intensity* is given by the value of its selective coefficient. Hence it follows that if the selective coefficients are not identical in value, the ratios are as follows:

$$\frac{\text{Correspondent power for freq. 1}}{\text{Interferent power for freq. 1}} : \frac{\text{Correspondent power for freq. 2}}{\text{interferent power for freq. 2}}$$

$= (T_r)\ (S_c)$ for freq. 1: $(T_r)\ (S_c)$ for freq. 2

Therefore for the purpose of receiving through troublesome interference, the product of

(transmission efficiency) × (selective coefficient)

may be characterized as the "Figure of Merit of the frequency (with antenna costs neglected) *when receiving with a plain series antenna.*" Under these conditions the comparison between the frequencies reduces to this: The merit of the low frequency is its higher transmission efficiency: its demerits are its lower selective coefficient, the greater volumes of the antennas which must be used at the sending and receiving stations, and the lower radiating efficiency of the sending station.

At this point we discontinue the discussion of the plain antenna circuit, because coupled circuits must be used to obtain higher selective coefficients. When the detector is associated, not directly with the antenna circuit, but with a tuned secondary or tertiary circuit, the selective coefficient of the system against detuned alternating electromotive forces varies as the fourth or the sixth power of the resonant frequency. Hence the higher frequencies have an additional advantage which tends to shift the optimum frequency toward the higher values. This discussion of the properties of the antenna circuit is a necessary preliminary to the study of the possibilities of the antenna combined with additional sifting circuits.

COAL SUPPLY

The month of November has marked the passing of most of the Interstate Commerce Commission's restrictive orders on the use and transportation of coal. In general, these orders have produced the results for which they had been issued and the distribution of coal has for the most part returned to nearly normal conditions. The lifting of the late priority order for instance had the effect of releasing at least one-half of the 4000 cars which had been dumped daily at lower Lake ports. During the latter part of the time that the Lake order was in effect the refusal of the Northwest to buy resulted in a large number of cars being held underloaded. With the lifting of the order, however, this accumulation of coal on cars was hurried into distribution with the result that very substantial relief was given in the Middle West. After coal began to move in this way its rate of transportation was soon slowed down however, because there were no automatic unloading arrangements such as there had been at the Lake Port.

The National Committee on gas and electric service is working in cooperation with the Interstate Commerce Commission and a number of emergencies have been taken care of by them. This committee is composed of representatives of the operators of the railroads and of public utilities. It is understood that they will have increased difficulties in meeting the situation as the effects of the Interstate Commerce Commission's service orders are removed. It is expected that the principal difficulty will be in supplying the public utilities that have small stocks of coal which cannot be readily replenished if extremely bad weather sets in.

There is evidence that spot coal will continue to sell for some time to come at a higher figure than most contracts. There will be a resultant tendency to sell on the open market rather than comply with the terms of the contract. Although it is pointed out that between 80 and 90 per cent of the requirements of the gas and electric companies are covered by contracts, it may be some time before they are able to build up their reserves however.

In the event that the East and Middle West experience severe winter weather before the first of the year it is feared that a large number of public utility plants will be forced to suspend operation due to the fact that they have no reserve stock of coal. Since through the control of the coal supply the Interstate Commerce Commission has the responsibility of public utility service throughout the country, the situation has been carefully laid before them by the utility interests and their optimistic views will probably be effected accordingly.

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

A. I. E. E. AKRON-CLEVELAND MEETING, JANUARY 14, 1921

The 366th meeting of the A. I. E. E. will be held in Akron and Cleveland, Ohio, on January 14th, 1921. According to the tentative plans which are being developed by the Meetings and Papers Committee, members attending the meeting will assemble in Akron, where an inspection of the Goodrich Rubber Plant will take place during the afternoon. Special cars will take the party from Akron to Cleveland in time for dinner in Cleveland, after which there will be a technical session during the evening.

The Board of Directors will hold its regular monthly meeting at 9.30 a.m. in Akron, and any committees that wish to hold meetings that day are expected to hold them in Akron during the morning.

The general subject of the technical session will be "Rubber Mill Electrification." Several papers on different phases of this subject will be presented under the auspices of the Industrial Power Committee. The program in detail will be printed in the January JOURNAL. The general arrangements of the meeting will be under joint auspices of the Akron and Cleveland Sections.

A. I. E. E. MIDWINTER CONVENTION

The Midwinter Convention, according to the original plans of the Meetings and Papers Committee, was to have been held February 23-25, 1921, as announced in the November JOURNAL. It has been found advisable, however, to advance the time of holding the Convention, and at the suggestion of the Board of Directors the Midwinter Convention will be held February 16-18, a week earlier than originally planned.

NEW YORK SECTION MEETING, DECEMBER 3

A joint meeting of the New York Section of the A. I. E. E., Management and Metropolitan Sections of the A. S. M. E., and the Taylor Society will be held in the auditorium of the Engineering Societies Building, 33 West 39th Street, New York, December 3rd, at 8 p. m. The general subject of the meeting will be "The Long Day in the Steel Industry," and three addresses will be given as follows: *Introductory Remarks*, by Fred J. Miller, President of the A. S. M. E., who will preside; *The Three-Shift System in the Steel Industry*, by Horace B. Drury, recently with the Industrial Relations Division, U. S. Shipping Board; *The Point of View of the Manufacturer*, the speaker to be announced later.

Following the addresses a general discussion will take place, led by Robert B. Wolf, Consulting Engineer, New York, and several others prominent in the industry.

This meeting takes the place of that previously announced on "The American Power Problem," which subject has been unavoidably postponed.

FUTURE SECTION MEETINGS

Chicago.—December 17, 1920, Western Society of Engineers. Papers: "Economic Aspects of the Light Weight Safety Car," by H. A. Johnson, Organizing Engineer, Chicago, N. S. and Milwaukee Railway; "Train Operation on Surface Lines," by F. B. Way, Vice-President and General Manager, Milwaukee Elec. Railway & Light Company; "Substation Operation," by Charles H. Jones, Electrical Engineer, Chicago, North Shore & Milwaukee Railway.

January 24, 1920. Subject: "Research, A National Issue and How to Meet it in a Practical Way."

Cleveland.—December 21, 1920. Subject: "The Purchase and Use of Electric Motors from the Owners' Standpoint." Speaker: Mr. James Burke.

Lynn.—December 8, 1920. Subject: "Super-power Zone." Speaker: Mr. William S. Murray.

Pittsburgh.—December 14, 1920. Subject: "Wireless Development." Speaker: Mr. A. F. Van Dyck, General Electric Company.

Pittsfield.—December 16, 1920. Subject: "Ice Formation and Its Preventions." Speaker: Mr. John Murphy, Ottawa, Ontario.

January 20, 1921. Subject: "On the Frontiers of the Universe, or An Evening With the Stars." Speaker: Mr. B. R. Baumgardt, Lecturer, Los Angeles and New York.

Portland, Ore.—January 10, 1921. Subject: "Progress in the Electrical Industry on the Pacific Coast." Speaker: Mr. Robert Sibley.

Seattle.—December 21, 1920. Subject: "Recent Developments in Radio Engineering." Speaker: Mr. F. G. Simpson, Vice-President and General Manager, Kilbourne & Clark Mfg. Co.

CHICAGO MEETING

The Institute held its 365th meeting on Friday, November 12, in Chicago, under the auspices, jointly, of the Chicago Section and the Protective Devices Committee, with the Electrical Section of the Western Society of Engineers participating. The program as announced in a previous issue of the JOURNAL was carried out as arranged.

The following committees held meetings in the afternoon: Mines Committee, Membership Committee, Educational Committee, Protective Devices Committee. The Board of Directors held its regular monthly meeting at 3:00 o'clock at the headquarters of the Western Society of Engineers, where most of the committee meetings were held.

At the informal dinner at the City Club, Chairman J. R.

Bibbins of the Chicago Section presided, and brief addresses were made, both relating to the Federated American Engineering Societies, by President Berresford of the A. I. E. E., and President Copeland of the Western Society of Engineers.

President Berresford presided at the opening of the technical session during the presentation of Mr. Roper's paper, after which he turned the meeting over to Mr. Roper, Chairman of the Protective Devices Committee, who presided during the remainder of the session. The following papers were presented: *Studies in Lightning Protection on 4000-Volt Circuits-II*, by D. W. Roper, of the Commonwealth Edison Co.; *Lightning Arrester Spark Gaps-II*, by C. T. Allcutt, of the Westinghouse Electric & Mfg. Co.; *Life and Performance Tests of O F Lightning Arresters*, by N. A. Lougee, of the General Electric Company; and *Electrostatic Condensers*, by V. E. Goodwin, of the General Electric Co. All four authors were present and presented their papers in person.

Inspection trips were held on Saturday, to the Mark, Ind. Plant, Steel & Tube Company of America; the Automatic Substation of the Chicago, North Shore & Milwaukee Railway, Lake Bluff, Ill., and the Northwest Station, Commonwealth Edison Company.

A. I. E. E. DIRECTORS MEETING

NOVEMBER 12, 1920

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at the headquarters of the Western Society of Engineers, Chicago, on Friday, November 12, 1920, at 3.00 p. m.

There were present: President A. W. Berresford, Milwaukee; Vice-Presidents Charles S. Ruffner, New York, Charles Robbins, Pittsburgh, E. H. Martindale, Cleveland; Managers Wilfred Sykes, Chicago, L. F. Morehouse and E. B. Craft, New York, James F. Lincoln, Cleveland; Secretary F. L. Hutchinson, New York.

The Board ratified the approval by the Finance Committee of monthly bills amounting to $32,195.96.

The Secretary was authorized to remove from the membership list December 31, 1920, the names of all members in arrears for dues for the year ending April 30, 1920.

A report was presented of a meeting of the Board of Examiners held October 25, 1920; and upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 353 Students were ordered enrolled; 111 applicants were elected to the grade of Associate; 9 applicants were elected to the grade of Member.

Upon recommendation of the Board of Examiners the following Local Representatives of that Board were appointed for the present administrative year: C. L. Cory, San Francisco, Cal; L. A. Herdt, Montreal, Quebec; H. H. Humphrey, St. Louis, Mo.; D. W. Roper, Chicago, Ill.; A. M. Schoen, Atlanta, Ga.; J. F. Vaughan, Boston, Mass.

The Meetings and Papers Committee reported upon plans for future meetings including the meeting to be held on January 14, at Akron and Cleveland, Ohio, and a meeting to be held in Pittsburgh in April. Upon recommendation of the Pittsburgh Section and the Meetings and Papers Committee the Board voted to extend an invitation to the members of the Association of Iron and Steel Electrical Engineers to participate in the Pittsburgh meeting in April.

Following a brief discussion of the Annual Convention of 1921, including the present high costs of Institute's publications, the following resolutions were adopted:

RESOLVED that the attention of the Meetings and Papers and Publication Committes be called to the present financial condition of the Institute which has made necessary the omission in the budget for the present appropriation year of the sum required to complete the printing of the 1920 TRANSACTIONS; and that these committees be reminded that the appropriations for the activities within their jurisdiction for the present year are larger than ever before in the history of the Institute, but that on account of the increased costs of carrying on these activities it will be necessary for these committees to watch their appropriations very carefully, as there is little likelihood that it will be possible to grant any increase to the appropriations for the present year.

RESOLVED that the Board hereby confirms its action of last spring to the effect that the social features of the summer convention benefit and strengthen the technical interests of the Institute and the engineering profession, and reaffirms as a policy of the Institute that the principal meeting of the year for the presentation of technical papers shall be the Midwinter Convention, and that the program of the Annual Convention in June shall include only a limited number of technical papers, to be presented in not exceeding four sessions, with ample time for discussion; thus allowing time for excursions and other social features which may be arranged by the convention committee.

The following appointments of Institute representatives were made: H. H. Barnes, Jr., to Board of Trustees, United Engineering Society for term of three years commencing January 1921; E. B. Craft, to the Library Board, United Engineering Society, for term of four years commencing January 1921; H. M. Hobart, reappointed to American Engineering Standards Committee, for term of three years commencing January 1921; John Price Jackson, reappointed to Commission of Washington Award, for term of two years commencing January 1921.

The establishment of a Student Branch of the Institute at Case School of Applied Science, Cleveland, Ohio, was authorized.

Upon the recommendation of the special committee which had been appointed to consider a proposal of the Engineering Division of the National Research Council that the Institute assume sponsorship in the field of electrical engineering research in connection with the work of the Engineering Division, the Board authorized the appointment of a General Advisory Board on Electrical Engineering, of the Engineering Division of the National Research Council, which will also constitute the Institute's Research Committee.

In support of the activities of Engineering Council relative to the Patent Office, the following resolution was adopted:

RESOLVED that the Board of Directors of the American Institute of Electrical Engineers hereby endorses the resolutions adopted by Engineering Council at its meeting in Chicago relative to the desirability of obtaining adequate legislation in Congress for the support of the Patent Office, and directs that the matter be brought to the attention of the members of this Institute through publication in our monthly JOURNAL, and recommends that individual members communicate with their representatives and senators in Congress urging prompt action.

Upon request of Engineering Council for endorsement of the report of Council's Committee on Classification and Compensation of Engineers, which report had been printed some months ago in the JOURNAL, the following resolution was adopted:

RESOLVED that the Board of Directors of the American Institute of Electrical Engineers hereby endorses the report of Engineering Council's Committee on Classification and Compensation of Engineers which was published in the February 1920 issue of the JOURNAL of the A. I. E. E.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

NOMINATION AND ELECTION OF INSTITUTE OFFICERS FOR 1921-1922

As provided in Section 19 of the Institute By-Laws, candidates may now be proposed for nomination for the offices to be filled at the next annual election in May, 1921, by the petition or by the separate endorsement in writing, of not less than twenty-five members. The petitions or separate endorsements must be in the hands of the Secretary not later than January 25, 1921. For the convenience of members, a form of petition has been prepared by the Secretary, and copies of it may be obtained upon application to Institute headquarters. Endorsements may, however, be made by letter if the form is not available. A member is not limited in the number of candidates he may endorse in this manner.

The officers to be elected are: a President and a Treasurer

for the term of one year each, ten Vice-Presidents for the term of two years each, and three Managers for the term of four years each.

At the Annual Meeting of May 1920, amendments to the Constitution were adopted, carrying out the recommendations of the Committee on Development, in its report of August 12, 1919, that the membership be grouped into geographical districts, that one Vice-President be elected from each district and that Vice-Presidents hold office for a term of two years. The recommendation for the removal of the constitutional inhibition upon the election of a Vice-President as Manager was complied with and the immediate re-election of a Vice-President to the same office provided for with provision against too extended term of office. The former inhibition upon the re-election of a President or Manager to the same office was continued.

5. Great Lakes: Illinois, Indiana, Michigan, Wisconsin.

6. North Central: Colorado, Iowa, Minnesota, Nebraska, North Dakota, South Dakota, Wyoming.

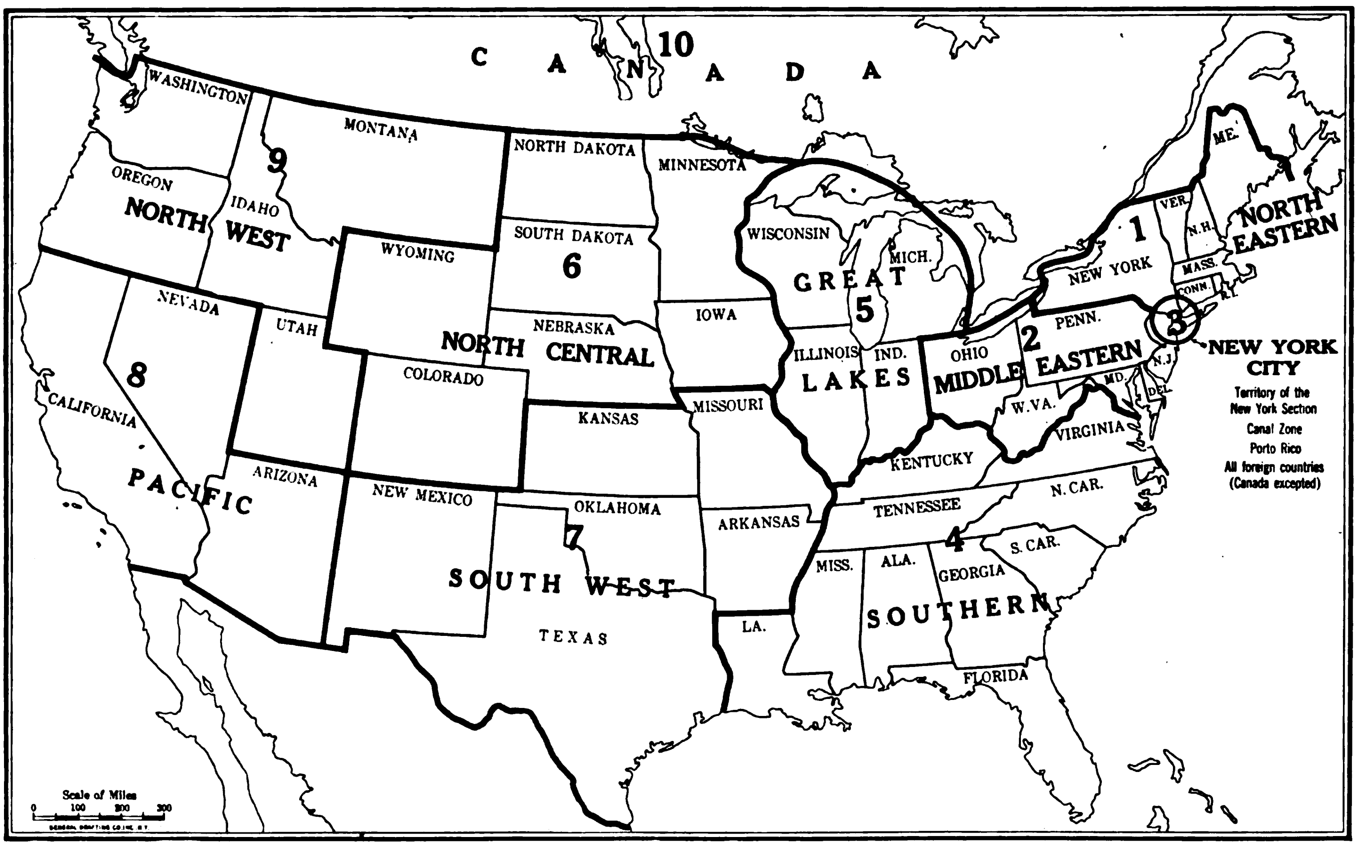
7. South West: Arkansas, Kansas, Missouri, New Mexico, Oklahoma, Texas.

8. Pacific: Arizona, California, Nevada, Hawaii, Philippines.

9. North West: Idaho, Montana, Oregon, Utah, Washington, Alaska.

10. Canada:

According to the revised Constitution one Vice-President must be elected from each geographical district but this does not debar members in one district, if they so wish, from nominating and voting for a candidate in another district. When the votes are counted the candidate for Vice-President having the largest vote in each district will be elected to that particular office for



Geographical Districts into Which the Membership of A. I. E. E. Has Been Divided for the Purpose of Electing Vice-Presidents

At the November 12 meeting of the Directors revisions of the By-Laws were adopted, including the definition of the ten geographical districts decided upon by the Committee on Geographical Divisions and Election Procedure. The ten districts defined in Section 21 of the By-Laws are, as follows:

1. North Eastern: Connecticut (exclusive of N. Y. Section territory), Maine, Massachusetts, New Hampshire, New York (exclusive of N. Y. Section territory), Rhode Island, Vermont.

2. Middle Eastern: Delaware, District of Columbia, Maryland, New Jersey (exclusive of N. Y. Section territory), Ohio, Pennsylvania, West Virginia.

3. New York City: Territory of the New York Section, Canal Zone, Porto Rico, all foreign countries (Canada excepted).

4. Southern: Alabama, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Virginia.

that district, irrespective of the fact that he may have polled a smaller number of votes than a man standing second in another district.

For the information of members the full text of revised sections of the Constitution and By-Laws applying to Officers, nominations, elections, etc., are printed below:

CONSTITUTION

Sec. 23. The officers of the Institute shall be a President, one Vice-President from each geographical district as defined in the By-Laws, twelve Managers, a Secretary and a Treasurer.

Sec. 24. The President, the Secretary and the Treasurer shall hold office for one year, the Vice-Presidents for two years and the Managers for four years. The President and Managers shall not be eligible for immediate re-election to the same office. No Vice-President or Manager who has served continuously in one or more offices, and whose combined terms shall have aggregated six years or more, shall be eligible for immediate election to the office of Manager or Vice-President. At each Annual Meeting the President, the requisite number of Vice-Presidents to fill vacancies caused by expiration of terms, three Managers and the Treasurer shall be

elected by the membership, and their terms of office shall commence on the first of August next succeeding their election. . . . . . .

SEC. 24A. At the election of Vice-Presidents held in 1921 there shall be elected one Vice-President from each geographical district, those from the odd-numbered districts to serve for one year each, and those from the even-numbered districts two years each. All Vice-Presidents elected thereafter shall serve for two years each. In the event of a change in the geographical districts, the Vice-Presidents then in office shall complete their terms. In case of revisions of the geographical districts, the Board of Directors shall have the power to elect a Vice-President from each district not represented, to serve until the next election covering these districts.

BY-LAWS

SEC. 19. In addition to the names of the incumbents of office the Secretary shall publish on the "form showing offices to be filled at the ensuing annual election in May provided for in Article VI, of the Constitution, the names, as candidates for nomination, of such members of the Institute as have been proposed for nomination for a particular office by the petition or by the separate endorsement of not less than twenty-five members, received by the Secretary of the Institute in writing by January twenty-fifth of each year; provided, however, that any candidate proposed for nomination by petition may withdraw his name by written communication to the Secretary, and any name so withdrawn prior to the printing of the form shall not be published.

The names of such candidates for nomination shall be grouped alphabetically under the name of the office for which each is proposed, and this by-law shall be reprinted prominently in the December and January issue of each year's JOURNAL and shall be reproduced on the form above referred to.

SEC. 21. There shall be ten geographical districts grouped as follows: (For the balance of this Section describing districts see paragraph preceding map.)

SEC. 21A. Should the territory of any Institute Section lie in more than one geographical district as defined above, then the entire territory of said Section shall be considered as belonging to the geographical district in which the headquarters of the Section are located.

NEW YORK SECTION OF CIVIL ENGINEERS MEETS DECEMBER 15

The New York Section of the American Society of Civil Engineers has extended a special invitation to the membership of the New York Section of the American Institute of Electrical Engineers to attend a meeting on December 15th at which the subject of discussion will be "The Port of New York." The meeting will be held on the fifth floor of the Engineering Societies Building, and will be called to order at 7.45 p.m. The subject will be introduced by Mr. B. F. Cresson, and the following gentlemen have been invited, and are expected to participate in the discussion: Geo. S. Webster, F. W. Cowie, E. P. Goodrich, Murray Hulbert, Frank L. Williams, G. F. Nicholson, Geo. T. Hand, F. L. Stuart, J. J. Mantell, A. W. Robinson, John Meigs, P. A. S. Franklin, Irving T. Bush and F. T. Chambers.

THE INSTITUTION OF CIVIL ENGINEERS INVITES A. I. E. E. TO PARTICIPATE IN ENGINEERING CONFERENCE

The following letter has been received by the Secretary inviting members of the Institute to participate in an Engineering Conference, to be held under the auspices of the Institution of Civil Engineers. Members in England at the time designated are urged to accept the invitation and join in the discussion.

The Institution of Civil Engineers
Great George St., Westminster, S. W. I.
October 29, 1920.

The Secretary,
American Institute of Electrical Engineers,
New York, N. Y.

My dear Sir,

I am directed by the Council to inform you that it is proposed to hold at this Institution in the summer of next year, probably at the end of June, another general Engineering Conference—the series of which was unfortunately broken by the European War. At these Conferences which have been generally of three days' duration, questions are introduced, with a view to discussion on important problems of the day arising in or affecting the various departments of engineering, including the education and training of engineers; and in the past these discussions have enjoyed very considerable support and success.

The Council now wish me to say to you, and through you to the members of the American Institute of Electrical Engineers, that any members of your Society who may be in England at the time of the Engineering Conference referred to are cordially invited to take part in it, and to contribute to the discussion of the subjects that may be submitted at the Conference.

Yours faithfully,
J. H. T. TUDSBERRY,
Secretary.

ANNUAL MEETING OF A. S. M. E.

The American Society of Mechanical Engineers will hold its Forty-first Annual Meeting, December 7-10, 1920, in the Engineering Societies Building, 29 West 39th Street, New York. One of the features of the meeting will be a keynote session on Transportation, on December 9, at which addresses will be given as follows: *Railroads*, by Daniel E. Willard, President Baltimore & Ohio Railroad; *Railroad Feeders*, by Charles A. Morse, Chief Engineer, Chicago, Rock Island & Pacific Railroad; *Waterways*, by General Frank T. Hines; *Motor-Truck Transportation*, by Francis W. Davis, Engineer, Pierce-Arrow Motor Car Company; *Terminals*, by Col. William Barclay Parsons, Consulting Engineer, New York City; and *The New York Terminal Problem*, by Gustav Lindenthal, Consulting Engineer, New York City. The program also includes sessions of Professional Sections on Fuels, Railroads, Management, Machine Shop, Textiles and Power, which promise to be of unusual value. Incorporated in the meeting will be a memorial service in honor of Dr. John A. Brashear, Past-President of the Society. Dr. Henry Smith Pritchett, President of the Carnegie Foundation for the Advancement of Teaching, will deliver the eulogy on Dr. Brashear, on Wednesday evening, December 8.

FORTIETH ANNIVERSARY OF THE A. S. M. E.

The fortieth anniversary of the founding of the American Society of Mechanical Engineers was celebrated at a meeting held November 5, 1920, at the Engineering Societies Building, 33 West 39th Street, New York. This celebration was one of thirty-two similar meetings held simultaneously in some of the larger cities throughout the country. Messages of congratulations were received from a number of prominent men, including President-Elect Warren G. Harding, Vice-President-Elect Calvin Coolidge, Herbert Hoover, and Charles M. Schwab.

The subject of the meeting was "The Opportunity and Responsibility of the Engineer," and addresses were made by Samuel Gompers, President of the American Federation of Labor, William B. Dickson, Vice-President of the Midvale Steel and Ordnance Company, J. Herbert Case, Acting Governor of the Federal Reserve Bank Fred J. Miller, President of the Society, William L. Saunders, Past-President of the American Institute of Mining and Metallurgical Engineers, Henry R. Towne, A. P. Davis, President of the American Society of Civil Engineers, and Charles F. Scott, Past-President of the American Institute of Electrical Engineers.

ANNUAL MEETING OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

The seventy-third meeting of the American Association for the Advancement of Science, together with meetings of a large number of the national scientific societies that are associated with it, will be held in Chicago, from December 27, 1920, to January 1, 1921. Dr. L. O. Howard, Chief of the Bureau of Entomology, U. S. Department of Agriculture, who has been permanent secretary of the Association for 22 very successful years—during which time the membership has been increased

from 1,729 to about 13,000—is president-elect and will preside at the Chicago meeting. The address of the retiring president, given at the opening general session of the Association, will be by Dr. Simon Flexner, Director of the Rockefeller Institute for Medical Research.

GEORGIA CITIZENS VISIT ENGINEERING SOCIETIES BUILDING

On November 23rd about one hundred and fifty citizens of Georgia, including Governor Hugh M. Dorsey and staff, and President K. G. Matheson of the Georgia School of Technology, visited New York during their tour to many of the principal industrial centers of the country for the purpose of investigating the progress that is being made in industrial research, the ultimate object being the encouragement of research in Georgia.

Members of the party were the guests of the Merchants' Association of New York at luncheon, after which they visited the Engineering Societies Building where a brief special meeting was held in the auditorium. President J. V. Davies of the United Engineering Society extended a welcome and briefly explained the scope of the national engineering societies and their relation to research work through the Engineering Foundation, The National Research Council, Engineering Council, Engineerings Societies Library, etc. Governor Dorsey responded and brief addresses were also made by Professor Walter Rautenstrauch of Columbia University, President Matheson of the Georgia School of Technology, Director Harrison W. Craver of the Engineering Societies Library, Mr. Phinehas V. Stephens and others, after which the party was escorted through the building in small groups by Reception Committees representing the national societies. The Institute's representation consisted of: Messrs. C. S. Ruffner, Chairman, H. H. Barnes, Jr., E. B. Craft, H. H. Norris, H. A. Pratt, W. I. Slichter and Secretary Hutchinson.

In the evening the Georgians were the guests of the Georgia Society at dinner, after which they returned to their special train, which left at midnight for Washington.

SHELDON MEMORIAL EXERCISES

Interesting and impressive exercises in memory of Dr. Samuel Sheldon were held in the main auditorium of the Engineering Societies Building on the evening of November 17, and were well attended in spite of inclement weather.

The meeting was conducted by President Arthur W. Berresford, who as a graduate under Dr. Sheldon at the Brooklyn Polytechnic Institute. class of '92, was able to give a number of personal reminiscences in an admirable address, which referred briefly also to the work of his predecessor in various A. I. E. E. capacities and as an efficient president in 1906-7.

Dr. A. E. Kennelly, Professor of Electrical Engineering, Harvard and Massachusetts "Tech," gave a masterly address dealing principally with Dr. Sheldon's work as an engineer, author and educator. It is to be remembered that prior to the work begun by Dr. Sheldon in Brooklyn in 1889, courses of study in America in electrical engineering were limited and in a formative, constructive stage. The classes, the profession, the industries had all grown in an extraordinary manner; and Dr. Sheldon had kept abreast of it all down to the very last. Dr. Kennelly in speaking of the influence thus exerted made a charming comparison with the ever widening waves emanating from a great radio source of energy. He dwelt also upon the very lovable human qualities of their friend and colaborer.

Mr. Bancroft Gherardi was to have spoken on behalf of the United Engineering Society and its allied agencies with which Dr. Sheldon was associated for several years, but was called out of town on very important business. From a thousand miles away he sent a message to the meeting by long distance telephone expressive of his sentiments as a friend and admirer of Dr. Sheldon and as one who had been glad to be among his students at the Polytechnic.

President W. N. Dickinson of the New York Electrical Society made a very interesting address giving some of his own personal reminiscences of study at the "Poly" under the Sheldon regime, and summing up the year's work of his predecessor as head of the oldest American electrical engineering society in 1902-3.

Such topics were authoritatively considered then as wireless telegraphy, the steam turbine, radio active substances, motor drive of machine tools, electrical insurance conditions; A. I. E. E. high pressure standards electric elevators and submarine cables.

Dr. William H. Nichols, chairman of the board of trustees of the Brooklyn Polytechnic, made a forceful speech and spoke in glowing terms of "Sammy" as all loved to call him, emphasizing the Doctor's good work and influence, and insisting that means should be found to carry them into the future while perpetuating a memory that could not be allowed to die.

Mr. T. C. Martin on behalf of the Engineers Club and fellow members there touched upon the pleasant memories of Dr. Sheldon in the Club and his enjoyment of its friendly relationships and social intercourse. As chairman of the Sheldon Memorial Committee, Mr. Martin also drew attention to the formal resolutions of regret adopted and forwarded by the American Institute of Electrical Engineers, the New York Electrical Society, the United Engineering Society, the Engineering Foundation and the Library Board. He also stated that the Committee had received a large number of appreciations, including three from Past-Presidents Chas. F. Scott, Paul M. Lincoln and Calvert Townley. Several letters, he said, as instanced by one that he read, had been received urging the creation of a permanent memorial, and expressing the desire to contribute. Referring to the fact that Dr. Sheldon had begun his student work abroad under Kohlrausch in determining the ohm, he expressed the belief that Dr. C. O. Mailloux as President of the International Electrotechnical Commission, might fitly give a broader aspect to their local exercises that evening, as representing the authority now virtually continuing such work for the world at large.

Dr. Mailloux who it had been feared could not attend, then made a brief but forcible appeal for a permanent memorial, and voiced the sentiment of the audience in giving a mandate to the committee to proceed until that end had been accomplished.

On Monday, November 22, the Sheldon Memorial Committee met, reorganized and reelected Mr. T. C. Martin as chairman and Dr. Erich Hausmann as secretary. In view of the unanimous vote to raise funds for a Sheldon Foundation, Mr. Charles E. Potts, of the Committee and treasurer of the Polytechnic Institute, was elected as treasurer. Literature was also approved for launching an appeal to the public for funds and a letter was received from Mr. W. A. White of the Polytechnic Corporation, appoving heartily of the movement and contributing $1000. In the meantime it was voted to make a permanent record of the memorial meeting, letters of regret and appreciation, resolutions etc., and deposit it for preservation in the Institute archives in Brooklyn.

FEDERATED AMERICAN ENGINEERING SOCIETIES

ORGANIZATION MEETING OF AMERICAN ENGINEERING COUNCIL, WASHINGTON, D. C. NOVEMBER 18-20, 1920

The organization meeting of the American Engineering Council, in Washington, November 18-20, successfully and enthusiastically brought into effect the recommendations made by the Joint Conference Committee of the Development Committees of the four national Societies of Civil, Mining, Mechanical and Electrical Engineers in their report to these four societies, under date of September 17, 1919.

The various steps leading up to this organization have been referred to from month to month in this JOURNAL covering a period of more than two years.

The following is a complete list of the societies that have already joined the Federation, and the names of the official representatives of these societies upon American Engineering Council.

Member Societies and Representatives

Alabama Technical Association
- Paul Wright, Birmingham, Ala.

American Institute of Chemical Engineers
- Allerton S. Cushman, Washington, D. C.
- Harrison E. Howe (*alternate*), Washington.

American Institute of Electrical Engineers
- Calvert Townley (*chairman*), New York.
- Comfort A. Adams, Cambridge, Mass.
- A. W. Berresford, Milwaukee.
- H. W. Buck, New York.
- F. L. Hutchinson, New York.
- W. A. Layman, St. Louis.
- William McClellan, Philadelphia.
- L. F. Morehouse, New York.
- Lewis T. Robinson, Schenectady.
- Charles S. Ruffner, New York
- Charles F. Scott, New Haven, Conn.
- Lewis B. Stillwell, New York.
- John H. Finney, (*alternate*), Washington, D. C.
- G. A. Waters, (*alternate*), St. Louis, Mo.

American Institute of Mining and Metallurgical Engineers
- Herbert Hoover, Palo Alto, Calif.
- J. Parke Channing, New York.
- Arthur S. Dwight, New York.
- Edwin Ludlow, New York.
- Allen H. Rogers, Boston, Mass.
- Philip N. Moore, St. Louis.
- John V. W. Reynders, New York.
- Joseph W. Richards, Bethlehem, Pa.
- Percy A. Barbour (*alternate*), New York.

American Society of Agricultural Engineers, Ames, Iowa
- Samuel H. McCrory, Washington.

American Society of Mechanical Engineers
- L. P. Alford, (*chairman*), New York.
- Charles T. Main, Boston, Mass.
- Arthur M. Greene, Jr., Troy, N. Y.
- E. S. Carman, Cleveland, Ohio.
- Arthur L. Rice, Chicago, Ill.
- Dexter S. Kimball, Ithaca, N. Y.
- Paul Wright, Birmingham, Ala.
- W. A. Hanley, Indianapolis.
- William B Gregory, New Orleans.
- V. M. Palmer, Rochester, N. Y.
- H. P. Porter, Tulsa, Okla.
- Robert H. Fernald, Philadelphia.
- L. C. Nordmeyer, St. Louis.
- Fred J. Miller (*alternate*), Centre Bridge, Pa.
- Robert Sibley (*alternate*), San Francisco, Calif.
- Charles Whiting Baker (*alternate*), New York.

Associated Engineering Societies of St. Louis, Mo.
- William E Rolfe, St. Louis.

Detroit Engineering Society
- D. J. Sterrett, Detroit.

Engineering Association of Nashville
- C B. Howard, Nashville.

Engineering Society of Buffalo
- W. B. Powell, Buffalo, N. Y.

Grand Rapids Engineering Society
- Burritt A. Parks, Grand Rapids, Mich.

Kansas Engineering Society
- Lloyd B. Smith, Topeka, Kan.

Louisiana Engineering Society
- William B. Gregory, New Orleans, La.

Mohawk Valley Engineers' Club
- Byron E. White, Utica, N. Y.

Taylor Society, New York
- Morris L. Cooke, Philadelphia, Pa.

Technical Club of Dallas
- O. H. Koch, Dallas, Tex.

The Cleveland Engineering Society
- John F. Oberlin, Cleveland.

The Engineers' Club of Baltimore
- W. W. Varney, Baltimore.

The Society of Industrial Engineers, Chicago, Ill.
- L. W. Wallace, Baltimore, Md.
- F. S. Webner, (*alternate*), Washington.

Washington Society of Engineers
- E. C. Barnard, Washington.

York Engineering Society
- William J. Fisher, York, Pa.
- H. A. Delano (*alternate*), York, Pa.

The following is a list of the organizations which participated in the Washington meeting, but which have not yet officially become members of the Federation, together with the names of their delegates.

Participating Organizations and Delegates*

American Institute of Architects
- Percy C. Adams, Washington, D. C.

American Society of Heating and Ventilating Engineers
- Champlain L. Riley, New York, N. Y.

American Society for Testing Materials
- C. D. Young, Reading, Pa.
- C. L. Warwick, Philadelphia, Pa.

Engineering Society of Western Mass.
- Chas. L. Newcomb.

Florida Engineering Society
- L. R. McLain, St. Augustine, Fla.

Illuminating Engineering Society
- Walter C. Allen, Washington, D. C

Iowa Engineering Society
- John H. Dunlap, Iowa City, Iowa.

Joint Technical Council of San Francisco, Cal.
- Robt. Sibley, San Francisco.

National Fire Protection Association, Boston, Mass.
- Ira H. Woolson, New York, N. Y.
- D. Knickerbacker Boyd, Philadelphia, Pa.

Society of Automotive Engineers
- Howard E. Coffin, (*Chairman*), Detroit, Mich.
- David Beecroft, New York, N. Y.
- Coker F. Clarkson, New York, N. Y.
- H. M. Crane, New York, N. Y.
- C. F. Kettering, Dayton, Ohio.
- H. M. Swetland, New York, N. Y.

Society for the Promotion of Engineering Education
- F. L. Bishop, Pittsburgh, Pa

Temporary Organization

The opening session on Thursday morning, November 18, 1920, was called to order by Richard L. Humphrey, Chairman of the Joint Conference Committee, which had acted as the organizing

*These organizations are either considering or have given the matter of membership favorable consideration but have not taken final action.

committee of the meeting in accordance with the action of the preliminary organizing conference held in Washington in June 1920. Mr. Humphrey made a brief address reviewing the steps that had been taken toward organizing the Federation since last spring, including the preparation of a suggested program for this meeting.

Mr. Humphrey said in part, "You are embarking on a broad field of activity under the critical but hopeful eyes of the entire engineering and allied technical professions. It, therefore, behooves you to maintain the high ideals and add to the traditions of these professions. The unanimity of desire of the allied engineering and technical professions for a comprehensive organization that can speak for them in matters of public welfare, where technical training and engineering experience are involved, as well as in matters of common concern to these professions, culminated in the unanimous creation of The Federated American Engineering Societies and of its governing board, American Engineering Council—and has attracted a world-wide interest. Those who desire this comprehensive body are looking with confidence to the results of your labors. A great responsibility, therefore, rests upon you—that of justifying this confidence. The first step in realizing the dream of the engineering and allied technical professions for solidarity has been taken. The development of this solidarity is in the hands of the representatives of the Member Societies of The Federated American Engineering Societies. The profession is looking with intense interest to this meeting and is hopefully anticipating forward work. The confidence which the speaker felt and voiced in his opening remarks at the Organizing Conference concerning the success of that meeting he now feels in far greater measure for the success of The Federated American Engineering Societies in accomplishing the desired end of solidarity in the engineering and allied technical organizations, because of the great and growing enthusiasm for this organization; with no desire to repeat his previous address at the opening of the organizing Conference on June 3, the speaker wishes to emphasize that in his judgment the keynote of that meeting was the 'desire first to serve our country, and, second, to serve the societies and organizations of which we are the representatives.' And it would seem to the speaker from all the circumstances which have led up to the creation of this organization, that the keynote of whatever policy you may agree upon now should be 'Service.' Indeed, the organization by the preamble adopted at the Organizing Conference, at which it was created, is dedicated to the service of the City, State and Nation. In living up to this, you should carefully guard each act and each step in the progress of the organization, to the end that The Federated American Engineering Societies shall stand for the highest possible ideals and shall enrich the glorious traditions of the engineering and allied technical professions."

The temporary organization of the Council was then effected. Mr. Edwin S. Carman, of Cleveland, President-Elect of the American Society of Mechanical Engineers, was elected temporary Chairman; Mr. William E. Rolfe, of St. Louis, temporary Secretary.

Chairman Carman took the chair and the roll call of Societies and their delegates followed. All the societies listed on the program were represented. It was voted that participating organizations which were represented by delegates but which had not yet become members of the Federated Societies be given the privilege of the floor throughout this meeting of the American Engineering Council.

Temporary committees were appointed as follows:

Credentials. Messrs. O. H. Koch (Chairman), A F Ganier, S. H. McCrory, L. F. Morehouse, John J. Oberlin, B. A. Parks, Charles S. Ruffner.

Program. Messrs. Percy E. Barbour (Chairman), W. J. Fisher, W. B. Gregory, H. E. Howe, V. M. Palmer, W. W. Varney, G. A. Waters, P. Wright.

Constitution and By-Laws. Messrs. C. F. Scott (Chairman), R. H. Fernald, A. F. Ganier, C. T. Main, William McClellan, A. L. Rice, A. H. Rogers, W. E. Rolfe, B. E. White.

Nominations. Messrs. W. B. Powell (Chairman), L. P. Alford, E. C. Barnard, A. W. Berresford, W. B. Gregory, W. A. Hanley, D. S. Kimball, E. Ludlow, Wm. McClellan, W. E. Rolfe, L. B. Smith, L. B. Stillwell, L. W. Wallace.

Plan and Scope. Messrs. L. C. Nordmeyer (Chairman), H. Hoover, H. E. Howe, S. H. McCrory, J. F. Oberlin, V. M. Palmer, D. J. Sterrett, C. Townley, B. E. White.

Budget. Messrs. Calvert Townley, (Chairman), J. Parke Channing, A. M. Greene, W. B. Gregory, F. L. Hutchinson, O. H. Koch, B. E. Parks, Jos. W. Richards, D. J. Sterrett, W. W. Varney.

Resolutions. Messrs. F. S. Webner (Chairman), E. C. Barnard, J. H. Finney, P. N. Moore, L. B. Smith, P. Wright.

The representative named as Chairman of each committee was a temporary appointment to call the committee together; as soon as the committee convened it was to elect its own chairman. A motion was also passed to the effect that when a delegate or representative was absent and an alternate had been chosen, the alternate take the place of the representative or delegate or both on committees and in voting.

Location of Headquarters

The discussion on this topic was opened by Mr. Philip N. Moore, who favored Washington as the headquarters. Mr. Moore was followed by Mr. Calvert Townley, who did not advocate any particular place for headquarters but favored referring the decision of this important question to the Executive Board for consideration after all the essential facts bearing upon the matter were obtainable. Considerable discussion took place on this item, and a motion was finally made and seconded as follows:

> MOVED: That it is the sense of this meeting that the headquarters should be established in Washington.

The question was laid on the table for further debate until the afternoon. At that time the question was further discussed. Several amendments to the motion were suggested but did not carry, one of the amendments so lost being to the effect that the matter be referred to the Executive Board. On a rising vote of 29 affirmatives to 14 negatives, the above motion was adopted.

Employment Service

A statement regarding the Employment Service at present conducted under the auspices of the four Founder Societies, was made by Mr. F. L. Hutchinson, who briefly outlined the scope and extent of the work and presented a recent communication addressed to the Chairman of the Joint Conference Committee by Mr. Calvin W. Rice, Chairman of the Board of Direction of the Engineering Societies Service Bureau, containing recommendations regarding the funds that should be appropriated to continue the work advantageously during the coming year.

Mr. Hutchinson called attention to the fact that the Joint Finance Committee of the Founder Societies has adopted a recommendation recently to the effect that the employment activities be carried on after January 1, 1921, under the auspices of the American Engineering Council by a board consisting of the secretaries of all the societies represented in The Federated American Engineering Societies, and that these recommendations had been approved by the governing boards of the national societies of Mining, Mechanical and Electrical Engineers.

After some further discussion it was voted that the matter of conducting the Employment Service be referred to the Committee on Plan and Scope, which later reported favorably.

Committee on Credentials

This committee reported at the opening of the afternoon session on Thursday to the effect that the committee found that the printed list of representatives as printed on the preliminary

program was a complete list of the members of American Engineering Council and should be considered the official roll of the representatives on the Council. The committee then named certain alternates in addition to those named on the printed list and who had been appointed to attend this meeting in place of some of the official representatives who were absent.

It was voted to adopt the report of the Committee on Credentials, including acceptance of the credentials of the alternates named by the committee.

Committee on Program

The Committee on Program reported recommending that the tentative program as prepared by the Organizing Committee be approved as the program of this meeting, subject to such incidental revision as the presiding officer might deem desirable during the meeting.

This report was approved.

Engineering Council

Mr. J. Parke Channing, Chairman of Engineering Council, made a brief address relating to the activities of the Engineering Council, of which he had been Chairman during the past three years. (Most of these activities have been quite fully covered from month to month in the issues of the JOURNAL.)

Mr. Channing then said, "I would suggest that the new American Engineering Council follow in a general way the lines of Engineering Council based on its four years' experience. You will find that you will have to be most rigorous in determining what activities you may undertake and will have to turn down many suggestions which, though made in good faith, you will find are beyond the province of your Council. The broad principle which we have followed and which has been our motto is that 'Engineering Council is an organization of National Technical Societies of America, created to provide for consideration of matters of common concern to Engineers, as well as those of public welfare in which the profession is interested, in order that united action may be made possible.' Organized as you are with a broader support than Engineering Council, you will be able to make recommendations on State and local questions through local societies which are members of your body, by giving them information and instructing them on the broad principles which you support. You must be careful not to permit yourself to be used for movements which however good in themselves are not especially under the purview of engineers."

Mr. Alfred D. Flinn, Secretary of Engineering Council, Dr. D. S. Jacobus and Philip N. Moore also made brief statements relative to the activities of Engineering Council and including suggestions relative to the activities of the newly organized American Engineering Council.

Publicity

Mr. L. P. Alford called attention to the splendid cooperation of the technical press in giving publicity to the bulletins issued by the Joint Conference Committee containing information in regard to The Federated American Engineering Societies and American Engineering Council. He also called attention to the fact that the daily press was giving considerable publicity to engineering activities, and cited an instance where recently a single piece of engineering news was circulated to the extent of 2,500,000 copies of the papers of New York City.

Transportation

Mr. L. B. Stillwell, of New York, made a brief address on the broader features of transportation problems, including reference to the increasing use of motor truck transportation and the resulting effect upon the highways of the country.

Industrial Relations

At the opening session on Friday morning, November 19, 1920, Mr. L. W. Wallace of Baltimore, President of the Society of Industrial Engineers, made an address in which he emphasized the benefits, in industrial establishments, of the safety and welfare movements, medical departments and related service in these days of intensive and mass production. He made a plea for extension of the efforts to provide ample opportunity for the workmen to develop and become broader minded employees and citizens, fitted for advancement to the fullest possible extent.

Permanent Organization

The Committe on Nominations presented its report at the Friday morning session and recommended the election of the following officers:

President: (2 years)	Herbert Hoover, American Institute of Mining and Metallurgical Engineers
1st Vice-President: (2 years)	Calvert Townley, American Institute of Electrical Engineers
2nd Vice-President: (2 years)	William E. Rolfe, Associated Engineering Societies of St. Louis
3rd Vice-President: (1 year)	Dexter S. Kimball, American Society of of Mechanical Engineers
4th Vice-President: (1 year)	J. Parke Channing, American Institute of Mining and Metallurgical Engineers
Treasurer: (1 year)	L. W. Wallace, Society of Industrial Engineers

These officers were all unanimously elected. Vice-President Calvert Townley then took the chair, and the Vice-Presidents and Treasurer briefly expressed their appreciation of the honor of their election.

President Herbert Hoover was then escorted to the platform and in the brief address of acceptance expressed his strong conviction of the great field of usefulness of The Federated Body and The American Engineering Council, to the engineering profession and to the country.

Constitution and By-Laws

Professor Charles F. Scott presented a report of the Committee on Constitution and By-Laws, recommending that the Constitution and By-Laws which were tentatively approved at the preliminary conference in June 1920 be adopted, with a number of amendments.

After considerable discussion the meeting adjourned, and the same subject was continued at the afternoon session, when after further discussion, during which various amendments were suggested, the Constitution and By-Laws were adopted, including most of the amendments recommended by the committee. Some of these amendments were as follows:

> The name of the executive officer was changed from "Secretary" to "Executive Secretary."
>
> The provision in the tentative draft that no portion of the funds of The Federated American Engineering Societies should be "applied to the use of" local affiliations or State councils, was changed to read "no portion of such funds shall be appropriated for the operating expenses of local affiliations of State councils."
>
> The provision for holding the regular monthly meetings of the Executive Board was changed to provide for "regular meetings at least bi-monthly except during July and August" and also for a regular meeting to be held in connection with the meeting of the Council.
>
> The requirement that the contributions of member societies should be payable in advance in "semi-annual" payments, was changed to "quarterly" payments.

A few other amendments were adopted principally for the purpose of clarifying the meaning.

Plan and Scope

The report of the Committee on Plan and Scope was presented on Friday afternoon, and upon motion was accepted and referred to the Executive Board. The report follows:

The preamble to the Constitution lays down the cardinal principles that service to others is the keynote of the organization. To further this aim and to suggest concrete ways in which such services may be most effectively rendered, attention

is directed to certain general subjects upon which, among many others, such action may well be taken as may appear to the council or to the board to be most expedient.

Such services may take many different forms, and the extent to which it may be rendered will turn largely upon the question of financial ability to perform the service as well as upon the general question of the expediency or policy of entering into it.

One of the most fruitful and important fields of endeavor lies in the contact with governmental legislation, national, state and local, and rendering assistance in an advisory capacity, to the end that sound engineering principles may be adhered to. Assistance and advice to public bodies and officials on matters of a general engineering character and the suggestion or approval of competent engineering talent for a particular public service also forms an important object.

The fields of endeavor in which the Council and the Board may serve are of so widely varying a nature that it would be unwise to take any action which might unduly limit them in their activities. It should be a fundamental policy that subjects for consideration and action may be initiated by the executive Board itself as well as upon request or suggestion from outside sources, whether governmental or private.

The method of procedure of the original Engineering Council, whereby various subjects were handled through standing or special committees whose membership was composed of men best qualified to deal with specific subjects, regardless of whether they were members of the Council or not, is endorsed.

Among some of the topics which have heretofore engaged the attention of the Council and which illustrate the kind of activities in which this organization may well engage are:

1. To serve the public interest by investigation and advice to the public, and governmental and voluntary bodies, upon all local and national problems which involve industrial and economic question.
2. National Department of Public Works.
3. Conservation of natural resources, such as water, coal, oil, etc.
4. Maintenance of a cooperative attitude toward other national organizations, professional, industrial and commercial.
5. Technical education.
6. Transportation in its various forms, particularly highways.
7. Advice with and assistance to regional, state and local organization upon their request.
8. National Bureau of Economic Research.
9. Public Fire Protection.
10. Patents.
11. National Board of Jurisdictional Awards.
12. International affiliation of engineers.
13. State Organizations of local affiliations.
14. Uniform Licensing and Registration Laws.
15. Classification and Compensation of Engineers.
16. Employment service bureau.
17. Russian-American engineers committee.

The above list of suggested activities is illustrative only and is in no sense intended to limit the field of operation of the Executive Board.

Engineering Council's advice has already been sought and given upon the subject of Water Power and Water Conservation by the Federal Water Power Commission and by the State of Maine. From this beginning, it is fair to assume that the field for such service will constantly be enlarged until the organization becomes an invaluable aid in the formulation of broad public policies in which engineering is involved.

Every care should be exercised, however, to avoid any action partaking of political bias or partisanship and to keep the activities and pronouncements of the Federated American Engineering Societies within the pale of sound engineering, good judgment and upon the broad basis of a real and mutual cooperation.

Budget

The Committee on Budget, through Mr. Calvert Townley, Chairman, presented a report containing estimates of receipts and expenditures, based upon the facts obtainable at the time and a knowledge of the expenses of Engineering Council during the year 1920. Due to the fact that in addition to the societies already members of the Federated American Engineering Societies a number of others will probably become members within the next few months, the committee prepared both minimum and maximum estimates of receipts and expenses with totals as follows:

Estimated Income, Minimum, $59,000, Maximum, $80,000;
Estimated Expenses, Minimum, $56,500, Maximum, $93,500.

This tentative budget was submitted with a recommendation that it be referred for consideration to the Executive Board for such modifications as may be deemed desirable after further development of the plans for the coming year. The report was accepted and the recommendation adopted.

Executive Board

The plan of organization tentatively approved last June provided for an Executive Board of thirty members, charged with conducting the business of the federated organization under the direction of the Council, six of these to be the president, four vice-presidents, and treasurer elected by the Council, and twenty-four to be selected, a part by the national societies, and the remainder by the local, state, and regional organizations and affiliations according to districts—the number representing the national societies to bear as nearly as possible the same ratio to the number representing the local, state and regional organizations as the number of representatives of the national societies on the Council bears to the number of representatives of the local and regional organizations. Therefore, under this plan, the national and local organizations should select twenty-four members of the Executive Board.

It was voted, however, that only twenty members be elected at this time. The object of leaving four vacancies on the Executive Board was to allow societies which may become charter members in the near future to have an opportunity to be represented upon the Board. It was decided to elect at this time fourteen members from the national societies and six from the local organizations, one from each of six geographical districts which are specified below together with the names of the organizations within these districts that have already become members of the federation.

	Approximate Membership
District No. 1—New York and New England States	547
Buffalo Engineering Society	
Mohawk Valley Engineers Club	
District No. 2—Michigan, Wisconsin, Minnesota	704
Detroit Engineering Society	
Grand Rapids Engineering Society	
District No. 3—Ohio, Indiana, Illinois	1241
Cleveland Engineering Society	
District No. 4—New Jersey, Pennsylvania, Delaware, District of Columbia	850
York Engineering Society	
Baltimore Engineers Club	
Washington Society of Engineers	
District No. 5—Virginia, West Virginia, North and South Carolina, Alabama, Kentucky, Mississippi, Florida, Georgia, Louisiana, Texas	
Louisiana Engineering Society	
Technical Club of Dallas	
Alabama Technical Council	
Engineering Association of Nashville	
Florida Engineering Society	
District No. 6—North and South Dakota, Nebraska, Kansas, Oklahoma, Arkansas, Missouri, Iowa	836
Kansas Engineering Society	
Iowa Engineering Society	
Associated Engineers of St. Louis	

Territory west of the above has not been divided into districts.

At the Friday afternoon session the following elections as

members of the Executive Board were announced, in accordance with the above plan:

NATIONAL SOCIETIES
- American Institute of Chemical Engineers:
  - Harrison E. Howe, Washington, D. C.
- American Institute of Electrical Engineers:
  - H. W. Buck, New York
  - William McClellan, Philadelphia
  - Charles F. Scott, New Haven
  - Lewis B. Stillwell, New York
- American Institute of Mining and Metallurgical Engineers:
  - Arthur S. Dwight, New York
  - Edwin Ludlow, New York
  - Philip N. Moore, St. Louis
- American Society of Agricultural Engineers:
  - Samuel H. McCrory, Washington, D. C.
- American Society of Mechanical Engineers:
  - L. P. Alford, New York
  - Arthur M. Green, Jr., Troy, N.Y.
  - Edwin S. Carman, Cleveland
  - Fred J. Miller, Center Bridge, Pa.
- Taylor Society:
  - Morris L. Cooke, Philadelphia

LOCAL STATE AND REGIONAL ORGANIZATIONS
- District No 1: (To be selected later)
- District No. 2: (To be selected later)
- District No. 3: John F. Oberlin, The Cleveland Engineering Society
- District No. 4: William W. Varney, The Engineers Club of Baltimore
- District No. 5: O. H. Koch, Technical Club of Dallas, Texas
- District No. 6: Lloyd B. Smith, Kansas Engineering Society, Topeka, Kansas

Resolutions

Upon recommendation of the Committee on Resolutions it was voted to express to the four Founder Societies the obligation and appreciation of the Federated American Engineering Societies for the establishment of the Joint Conference Committee which carried forward the plan for the organization of the federation, including the present meeting; a resolution was adopted expressing appreciation of the wholehearted support given to the movement of the organization of the federation by the daily and technical press; also a resolution of thanks to the engineering societies of Washington for the many courtesies extended to the representatives attending this meeting.

A resolution was also adopted thanking the Chairman of the Joint Conference Committee of the Founder Societies for his able and untiring efforts over a long period of time toward the organization of this federation of engineering societies. Chairman Humphrey of the Joint Conference Committee briefly expressed his gratification at having been identified with the movement, and emphasized the fact that the keynote of the deliberations of the Council at this meeting has been "service."

The afternoon session closed with brief addresses by Professor Charles F. Scott and Mr. George G. Anderson, relating to the field of activities and the opportunities of the engineering profession for service in the solution of the great industrial, economic and social problems of the day.

Friday Evening Session

A large and enthusiastic audience attended the Friday evening session, at which President Hoover delivered an address on "Some Phases of Relationship of Engineering Societies to Public Service," which is published in full elsewhere in this issue. The latter part of the evening was devoted to an informal reception and smoker tendered by the engineering societies of Washington to the visitors. The occasion was exceedingly enjoyable to all present and afforded opportunity for renewal of old, and making of new, acquaintances.

EXECUTIVE BOARD MEETING

The orgnization meeting of the Executive Board of the Council was held at the New Willard Hotel on Saturday morning, November 20, Mr. William E. Rolfe, second Vice-President, presiding. Messrs. Calvert Townley and William E. Rolfe were elected Vice-Chairmen of the Executive Board. The following is a resume of the actions taken:

The following Committee was appointed to present to the Executive Board later a list of names of eligible persons for the office of Executive Secretary: Messrs. Wallace, Chairman, Alford, Moore, Oberlin, Scott, Townley and the President. Mr. Alford was elected temporary Executive Secretary, with headquarters in the offices of the American Society of Mechanical Engineers, New York.

The appointment of the following standing committees was referred to the President with power:

(a) Constitution and By-Laws
(b) Publicity and Publications
(c) Membership and Representation
(d) Finance
(e) Public Affairs

Headquarters to be opened in Washington as soon as possible; temporarily in connection with the Washington office of the present Engineering Council.

The preliminary budget prepared by the temporary Budget Committee and presented at the meeting of the Council on the previous day was referred to the Finance Committee of the Executive Board for consideration.

The proposed establishment of a National Department of Public Works was endorsed in the following resolution:

RESOLVED that this Board recognizes the great importance and value of the movement to establish a National Department of Public Works as inaugurated by Engineering Council and continued by the National Department of Public Works Association, and this Board declares itself n favor of continuing the efforts to that end.

The Patents Committee of the Engineering Council was authorized to act on behalf of the Federated American Engineering Societies in continuing its efforts toward the passage by Congress of legislation toward adequate support of the Patent office.

The Board endorsed the plan of President Hoover for investigation of industrial waste, and authorized him to organize a Committee for that purpose. This Committee will be the instrument through which the Council will deal with labor, chambers of commerce, and other agencies in the solution of the problems of industrial relations.

Questions relating to the payment of dues by different classes of membership were referred to the Committee on Membership and Representation.

The report of the Committee on Plan and Scope as published above was accepted.

The Board adjourned to meet again at the call of the President, not later than January 1921.

It may be interesting to review briefly the steps leading to the formation of the Federated American Engineering Societies, which may be said to have had their origin shortly after the armistice was signed in November 1918, at which time there was quite naturally a general tendency of organizations of all kinds to review their activities, with the object of ascertaining what changes in organization and methods were desirable.

The A. I. E. E. and many other national organizations appointed committees for this purpose. The Development Committee, which was the name given to the A. I. E. E. representatives charged with making this survey for their society, began its work by providing ample opportunity for the membership of the Institute to express views and make suggestions for the consideration of the Committee. This was done through publication of statements by the President of the Institute and the Chairman of the Development Committee in the Institute PROCEEDINGS. Every member of the Institute was requested to make suggestions, and all Sections of the Institute were invited and urged to hold special sessions for the purpose of discussing the activities of the Institute and what, if any changes, were desirable. More than half the Sections held such meetings and forwarded summaries of their discussions to the Develop-

ment Committee. Many individual members also contributed their views.

The final report of this Committee, voicing the views which had thus been expressed by the membership, contained, together with many other items, a recommendation to the effect that cooperation in matters of common interest to the engineering profession be studied through the Joint Conference Committee of the Development Committees of the four national societies of Civil, Mining, Mechanical and Electrical Engineers. The Development Committees of the other societies made similar recommendations, as a result of which a Joint Conference Committee representing the four national societies referred to was organized in 1919, which Joint Committee made recommendations in September 1919 culminating in the organization of the Federated Societies as an instrument through which the engineering profession may encourage the application of engineering principles to the solution of the broad industrial economic and social problems, many of which are briefly referred to above.

Summarizing the entire proceedings at the Washington meeting, the results are exceedingly gratifying, indicating a high degree of interest, and there is every indication that the activities of the American Engineering Council will be developed and extended to meet the generally expressed wishes of the membership of the various societies concerned, representing the engineering profession.

In its leading editorial of Saturday, November 20, the Washington Herald said:

"When the history of the year 1920 comes to be written by chroniclers and interpreters of its important events they will say that the formation in this city of the American Engineering Council of the Federated American Engineering Societies was epoch marking. Conceived during the war, born during a period of reconstruction, it has within it even as a child among institutions, a power that statesmen, politicians, taxpayers and plain folk must reckon on as henceforth important.

The persons who are affiliated with this newly constituted council are experts as compared with ordinary civilians or public officials. As human beings, taxpayers and democrats, they are weary of the unnecessary costs, the bureaucratic tyrannies and futilities and the nonrepresentative methods of carrying on public business. They learned their lesson during the war while aiding the government to function. That which they then learned they are bound all their fellow countrymen shall know. If the latter profit by the instructions and advice well and good. But as for the engineers they are out to fight to the bitter end to conserve national wealth, facilitate cheap and swift transportation of goods and passengers, pacify warring capital and labor, coordinate governmental machinery, and make the proved facts of applied science count for more with the average American citizen than the imaginative eloquence of the political orator or the subtly perverted instruction of the hired journalist."

SOME PHASES OF RELATIONSHIP OF ENGINEERING SOCIETIES TO PUBLIC SERVICE*

BY HERBERT HOOVER
President American Federated Engineering Societies

The Federation of Engineering Societies has been created for the sole purpose of public service. This initial meeting surely warrants some discussion of a few of the problems to which this organization, for expression of the engineering mind, can quite well give consideration.

One of the greatest of the problems before the country and, in fact, before the world, is that growing out of our industrial development. The enormous industrial expansion of the last fifty years has lifted the standard of living and comfort beyond any dream of our forefathers. Our economic system under which it has been accomplished has given stimulation to invention, to enterprise, to individual improvement of the highest order, yet it presents a series of human and social difficulties to the solution of which we are groping. The congestion of population is producing subnormal conditions of life. The vast repetitive operations are dulling the human mind. The intermittency of employment due to the bad coordination of industry, the great waves of unemployment in the ebb and flow of economic tides, produce infinite wastes and great suffering. Our business enterprises have become so large and complex that the old personal relationship between employer and worker has to a great extent disappeared. The aggregation of great wealth with its power of economic domination, presents social economic ills which we are constantly struggling to remedy.

I propose to traverse only a small fraction of these matters. I do not conceive that any man, or body of men, is capable of drafting in advance a plan that will solve these multiple difficulties and preserve the system which makes individual initiative possible. We have presented to us economic social patent medicines of one kind or another, and, in fact, the great panacea of Socialism is today in actual trial in its various forms. In Russia the attempt has been made to apply the most extreme form of complete Communism. The Russian experiment is bankrupt in production. The populations of our modern states have been built up to numbers dependent upon an intensity of production that can only be maintained by stimulation of individual effort through the impulse of self-interest, and a departure from this primary incentive to production has now been demonstrated to lead only to famine and flame and anarchy. We have even had a gigantic experiment imposed upon the United States by the war in the necessity to operate a vast merchant marine at the hands of the government, with a result that should offer little consolation to those who advocate even the mildest application of Socialism.

We have built up our civilization, both political, social and economic, on the foundation of individualism. We have found in the course of development of large industry upon this system that individual initiative can be destroyed by allowing the concentration of industry and service, and thus an economic domination of groups over the whole. We have therefore built up public agencies intended to preserve an equality of opportunity through control of possible economic domination. Our mass of regulation of public utilities and of many other types of industry aiming chiefly to prevent combinations in restraint of free enterprise, is a monument to our attempts to limit this economic domination—to give a square deal. This regulation is itself also proof of the abandonment of the unrestricted capitalism of Adam Smith. While our present system of individualism under controlled capitalism may not be perfect, the alternative offers nothing that warrants its abandonment. Our thought, therefore, needs to be directed to the improvement of this structure and not to its destruction.

A profound development of our economic system apart from control of capital and service during the last score of years has been the great growth and consolidation of voluntary local and national associations. These associations represent great eco-

*Address of Herbert Hoover before the Federated American Engineering Societies, November 19, 1920.

nomic groups of common purpose, and are quite apart from the great voluntary groups created solely for public service. We have the growth of great employers' associations, great farmers' associations, great merchants' associations, great bankers' associations, great labor associations—all economic groups striving by political agitation, propaganda and other measure to advance group interest. At times they come in sharp conflict with each other, and often enough charge each other with crimes against public interest. And to me one question of the successful development of our economic system rests upon whether we can turn the aspects of these great national associations towards coordination with each other in the solution of national economic problems, or whether they grow into groups for more violent conflict. The latter can spell breakdown to our entire national life.

This engineers' association stands somewhat apart among these economic groups in that it has no special economic interest for its members. Its only interest in the creation of a great national association is public service, to give voice to the thought of the engineers in these questions. And if the engineers, with their training in quantitative thought, with their intimate experience in industrial life, can be of service in bringing about cooperation between these great economic groups of special interests, they will have performed an extraordinary service. The engineers should be able to take an objective and detached point of view. They do not belong to the association of either employers or labor, of farmers, or merchants or bankers. Their calling in life is to offer expert service in constructive solution of problems, to the individuals in any of these groups. There is a wider vision of this expert service in giving the group service of engineers to group problems.

We have just passed through a period of unparalleled speculation, extravagance and waste. We shall now not only reap its inevitable harvest of unemployment and readjustment, but we shall feel the real effect of four years of world destruction, and from it economic and social problems will stand out in vivid disputation. One of the greatest conflicts rumbling up in the distance is that between the employer on one side and organized labor on the other. We hear a great deal from extremists on one side about the domination of the employer, and on the other about the domination of organized labor. Probably the tendency to domination exists among the extremists on both sides. One of the most perplexing difficulties in all discussion and action in these problems is to eliminate this same extremist. There are certain areas of conflict of interest, but there is between these groups a far greater area of common interest, and if we can find measures by which, through coöperation, the field of common interest could be organized, then the area of conflict could be in the largest degree eliminated.

In this connection the employer sometimes overlooks a fundamental fact in connection with organized labor in the United States. This is that the vast majority of its membership and of its direction are individualists in their attitude of mind and in their social outlook; that the expansion of socialist doctrines finds its most fertile area in the ignorance of many workers, and yet the labor organizations, as they stand today, are the greatest bulwark against socialism. On the other hand, some labor leaders overlook the fact that if we are to maintain our high standards of living, our productivity, it can only be in a society in which we maintain the utmost possible initiative on the part of the employer; and further, that in the long run we can only expand the standard of living by the steady increase of production and the creation of more goods for division over the same numbers.

The American Federation of Labor has publicly stated that it desires the support of the engineering skill of the United States in the development of methods for increasing production, and I believe it is the duty of our body to undertake a constructive consideration of these problems and to give assistance not only to the Federation of Labor but also to the other great economic organizations interested in this problem, such as the Employers' Association and the Chambers of Commerce.

It is primary to mention the three-phase waste in production; first, from intermittent employment, second from unemployment that arises in shifting of industrial currents, and third from strikes and lockouts. Beyond this elimination of waste there is another field of progress in the adoption of measures for positive increase in production.

In the elimination of the great waste and misery of intermittent employment and unemployment, we need at once coordination in economic groups. For example, our engineers have pointed out time and again to the bituminous coal industry where the bad economic functioning of that industry results in an average of but 180 days' employment per annum, where a great measure of solution could be had if a basis of cooperation could be found between the coal operators, the coal miners, the railways and the great consumers. The combined result would be a higher standard of living to the employees, a reduced risk to the operator, a fundamental expansion of economic life by cheaper fuel. With our necessary legislation against combination and the lack of any organizing force to bring about this cooperation, the industry is helpless unless we can develop some method of governmental interest, not in governmental ownership, but in stimulation of cooperation in better organization.

In help against the misery in the great field of seasonal and other unemployment, we indeed need an expansion and better organization of our local and federal labor exchanges. We have a vast amount of industry, seasonal in character, which must shift its labor complement to other industries. The individual worker is helpless to find the contacts necessary to make this shift unless the machinery for this purpose is provided for him.

In the questions of industrial conflict resulting in lockouts and strikes, one mitigating measure has been agreed upon in principle by all sections of the community. This is collective bargaining, by which, whenever possible, the parties should settle their difficulties before they start a fight.

It is founded not only on the sense of prevention but on the human right to consolidate the worker in a proper balanced position to uphold his rights against the consolidation of capital. This measure, advocated for years by organized labor, was agreed to by the employers' group in the First Industrial Conference, It has been supported on the platform of both political parties. The point where the universal application of collective bargaining has broken down is in the method of its execution. The conflict arises almost wholly over the question of representation and question of enforcement. The employer in some industries denies the right of men other than his own employees to conduct the negotiations. Labor organizations demand that, as such negotiations require skill, experience and bargaining freedom, they are of more then local application and that thus they can only protect the body of workers by presenting the case on their behalf by skilled negotiators.

The Second Industrial Conference, of which I was a member, proposed a solution to this point by the provision that where there was a conflict over representation, the determination should be left to a third and independent party. It also proposed that each party should have the right to summon skill and experience to its assistance. It further proposed that where one of the parties at dispute refuses to enter upon collective bargaining, the entire question should be referred to an independent tribunal for investigation as to the right and wrong of the whole dispute—but only for investigation and report. That conference, embracing both a great employer and a most distinguished representative of organized labor, was completely convinced that the illumination of the public mind as to the rights and wrongs of these contentions would in itself make for material progress in their solution, and that in public education and the condemnation of public opinion of wrong-doing lay the root to real progress. No group should be afraid of authori-

tative publicity in these matters, and I believe it would greatly advance an understanding of the cause of labor. The Conference did not believe that industrial contention could be cured by compulsory arbitration or any other form of governmental repression which must in the end use the jails for enforcement. The principles formulated by that conference should have your consideration.

There are questions in connection with this entire problem of employer and employees relationship, both in its aspects of increased production and in its aspects of wasteful unemployment, that deserve most careful study by our engineers. There lies at the heart of all these questions the great human conception that this is a community working for the benefit of its human members, not for the benefit of its machines or to aggrandise individuals; that if we would build up character and abilities and standard of living in our people, we must have regard to their leisure for citizenship, for recreation and for family life. These considerations, together with protection against strain, must be the fundamentals of determination of hours of labor. These factors being first protected, the maximum production of the country should become the dominating purpose. The precise hours of labor should and will vary with the varying conditions of trades and establishments, but the proper determination of hours, based upon these factors, is an immediate field demanding attention of engineers. There is no greater economic fallacy than the doctrine that the decrease of hours below these primary considerations makes for employment, of greater numbers, and it is an equal certainty that the 84-hour week of some employments transgresses these fundamentals to a point of inhumanity.

There is a broad question bearing upon stimulation of self-interest and thus increase in production that revolves around the method of wage payment. I need not review to you the advantages, difficulties and weaknesses of bonus, piece work, profit or saving sharing plans that are in use as a remedy for the deadening results of the same wage payment to good and bad skill alike. The suggestion I wish to put for your consideration is the possible use of another device in encouragement of individual interest and effort by creating two or three levels of wage in agreements for each trade, the position of each man in such scale to be based upon comparative skill and character. This plan should be developed upon the principle of graded extra compensation, for added skill and performance, above an agreed basic wage. In order to give confidence, the classification under such scales must be passed upon by representatives of the workers in such shop or department. This plan is now being successfully experimented with.

We must take account of the tendencies of our present repetitive industries to eliminate the creative instinct in its workers, to narrow their field of craftmanship, to discard entirely the contribution to industry that could be had from their minds as well as from their hands. Indeed, if we are to secure the development of our people, we cannot permit the dulling of these sensibilities. Indeed, we cannot accomplish increased prodution without their stimulation. Here again we cannot make an advance unless we can secure cooperation between the employer and the employee. In large industry this mutuality of interest that existed in small units cannot be restored without definite organization.

There has been a great increase in shop committees as a method of such organization. Where they have been elected by free and secret ballot among the workers, where they are dominated by a genius desire on both sides for mutual cooperation in the shop, they have resulted in great good. One of the most important phases of that good has been the tendency to turn the aspect of some foremen from that of slave-driving to leadership. And a great good has been possible by the encouragement of men to creative effort, in the stimulation of their minds as well as their hands to the solution of these problems. It makes for pride of craftmanship and is a real effort o offer them an opportunity of self-expression. Organized labor has opposed some forms of these committees because of the fear that they may break down trade organization covering the area of many different shops. There is economic reason for this fear in certain cases, deeper than appears upon the surface. One of the greatest accomplishments of organized labor has been the protection of the workers from the unfair employer, and it is worth the employer's notice that this is at the same time the protection of the fair employer from the unfair competition of the sweat shop. Again I believe the engineers could assist in the erection of a bridge of cooperation if organized labor, which has already made a beginning, would extend more widely its adoption of the principles of a shop committee settling its problems of wage and conditions of labor in general agreement and applying its energies through shop committee organization to development of production as well as to the correction of incidental grievance. There would be little outcry against the closed shop if it were closed in order to secure unity of purpose in constructive increase of production by offering to the employer the full value of the worker's mind and effort as well as his hands.

There is an immediate problem in increased production that is too often overlooked by the theorist. While it is easy to state that increased production will decrease cost and by providing a greater demand for goods secure increased consumption and ultimate greater employment, yet the early stages of this process do result in unemployment and great misery. It takes a variable period of time to create the increased area of consumption of cheapened commodities, and in the meantime, when this is translated to the individual worker he sees his particular mate thrown out of employment. We accomplish these results over long periods of time, but if we would secure cooperation to accomplish them rapidly we must take account of this unemployment and we must say to the community that if it is to benefit by the cheapening costs and thus the increased standard of living, or alternatively if the employer is to take the benefits, the entire burden should not be thrust upon the individual who now alone suffers from industrial changes. Nor can this be accomplished except by cooperation between groups. In fact, the whole problem of unemployment needs earnest consideration.

In summary, the main point that I wish to make is this: that there is a great area of common interest between the employer and the employees through the reduction of the great waste of voluntary and involuntary unemployment and in the increase of production. If we are to secure increased production and an increased standard of living, we must keep awake interest in creation, in craftsmanship and the contribution of the worker's *intelligence to management*.

Battle and destruction are a poor solution to these problems. The growing strength of national organizations on both sides should not and must not be contemplated as an alignment for battle. Battle quickly loses its rules of sportsmanship and adopts the rules of barbarism. These organizations—if our society is to go forward instead of backward—should be considered as the fortunate development of influential groups through which skill and mutual consideration can be assembled for cooperation to the solution of these questions. If we could secure this cooperation throughout all our economic groups, we should have provided a new economic system, based neither on the capitalism of Adam Smith nor upon the Socialism of Karl Marx. We should have provided a third alternative that preserves individual initiative, that stimulates it through protection from domination. We should have given a priceless gift to the Twentieth Century.

I am not one of these who anticipates the solution of these things in a day. Durable human progress has not been founded on long strides. But in your position as a party of the third part to many of these conflicting economic groups, with your lifelong training in quantitive thought, with your sole mental aspect of construction, you, the engineers, should be able to make contribution of those safe steps that make for real progress.

NATIONAL RESEARCH COUNCIL

A RESEARCH INFORMATION BUREAU

The National Research Council has established a Research Information Service as a general clearing-house and information bureau for scientific and industrial research. This "Service" on request supplies information concerning research problems, progress, laboratories, equipment, methods, publications, personnel, funds, etc.

Ordinarily inquiries are answered without charge. When this is impossible because of unusual difficulty in securing information, the inquirer is notified and supplied with an estimate of cost.

Much of the information assembled by this bureau is published promptly in the "Bulletin" or the "Reprint and Circular Series" of the National Research Council, but the purpose is to maintain complete up-to-date files in the general office of the Council.

Requests for information should be addressed, Research Information Service, National Research Council. 1701 Massachusetts Avenue, Washgington, D. C.

A CALL TO INSTITUTE MEMBERSHIP TO ASSIST IN PATENT LEGISLATION

As the Nolan Patent Office Bill (H. R. 11,984) will be brought before the Conference Committee of the House and Senate probably about the middle of December, and as the bill has been so altered by the Senate Committee as to be rendered almost worse than useless as a remedy for the present Patent Office troubles, an appeal is again made to the engineering profession to exert all possible influence towards its passage in original form, In this connection your Board of Directors at their meeting of November 12, 1920 adopted the following resolution:

RESOLVED that the Board of Directors of the American Institute of Electrical Engineers hereby endorses the resolutions adopted by Engineering Council at its meeting in Chicago, relative to the desirability of obtaining adequate legislation in Congress for the support of the Patent Office, and directs that the matter be brought to the attention of the members of the Institute through publication in our monthly JOURNAL and recommends that individual members communicate with their representatives and senators in Congress urging prompt action.

The appeal for action as issued by Engineering Council, containing detailed information follows:

An Appeal to the Members of the American Institute of Electrical Engineers on behalf of the Nolan Patent Office Bill H. R. 11,984

The members of the Institute will doubtless remember that they, in cooperation with the other engineering societies represented in Engineering Council, together with other scientific and industrial organizations, have been giving support to an effort to relieve the present desperate condition of the United States Patent Office by passing Nolan Patent Office Bill H. R. 11.984.

The purpose of this bill is to increase the examining and clerical forces of the Patent Office and to raise their salaries so as to give that office a sufficient force and at salaries that will attract and hold competent men to enable it to make its examinations with that reasonable promptness which is necessary to make it worth while applying for them and with such thoroughness as to reduce the percentage of errors to as low a limit as sufficient time for the work and proper qualifications can possibly effect.

Engineering Council appointed its Patent Committee for the purpose of aiding the Nolan bill and urged the membership of the constitutent societies to communicate with the Patent Committees of the House of Representatives and the Senate and with the Representatives and Senators from the districts and states of the respective members on behalf of the said bill. The influence thus exerted, and that of other organizations, was so powerful that, at a hearing before the Rules Committee of the House of Representatives, which was largely attended by officers of members of Engineering Council and of the said societies and organizations, the Nolan bill was ordered made special and the House of Representatives promptly passed it without amendment by a very large majority.

A similar hearing on the bill was held by the Patent Committee of the Senate, but, in order to remove the objection to unanimous consent to a special hearing by the Senate, before adjournment of the session, the Patent Committee of the Senate consented to amendments so seriously reducing the force and salaries of the bill as passed by the House of Representatives as to reduce the examining and clerical forces below the numbers now actually employed in the Patent Office. The increases of the salaries provided in the bill were also cut down to where they are seriously inadequate to attract or hold a sufficient number of qualified men to enable the Patent Office to do its work. The steady exodus of examiners from the Patent Office, which has been going on for some time, has not been stayed at all by the passsage of the bill by the Senate.

The bill was referred by the Senate to a Conference Committee of which the Senate members are:

Senator Geo. W. Norris, of Nebraska,
Senator Geo. B. Brandegee, of Connecticut, and
Senator William F. Kirby, of Arkansas.

The members of the Conference Committee for the House of Representatives have not been appointed, but Hon. John I. Nolan, of California, is certain to be one.

Engineering Council regarding the matter as of grave importance unanimously passed the following resolutions on October 21st, 1920:

Resolution of Engineering Council Concerning the Nolan Patent Office Bill H. R. 11,984.

WHEREAS, the United States Patent Office is vitally important to our industries, to induce the production of scientific and technical improvements and to enable our industries to keep abreast of those other countries; and

WHEREAS, the volume of work of the Patent Office for many years has increased much more rapidly than its examining and clerical forces have been increased, and the work in the past fiscal year has increased thirty-six per cent above the work of the previous year; and

WHEREAS, the salaries of examiners, except for a war bonus, have only been increased ten per cent in seventy years and are so low that resignations of examiners are constantly occurring in a steady stream, averaging twenty-five per cent per annum, and resulting in such frequent changes that much inefficiency unavoidably results therefrom, even where examiners are qualified for the work, and many men are necessarily employed as examiners who cannot pass the examination required to qualify for their positions; and the salaries of the clerical forces are considerably below the average of salaries for corresponding work in the governmental departments generally; and

WHEREAS, as a result of such situation, the Patent Office is at such a great disadvantage that it unavoidably grants an undue proportion of defective patents, resulting in heavy losses both to the inventors and the public, due to useless development and unnecessary litigation, and the Patent Office is so far behind in its work that the value of many transactions with it is greatly reduced and in some instances destroyed by delay; and

WHEREAS, as a partial remedy for such situation Nolan Bill H. R. 11,984 was introduced into Congress providing for an increase in the examining corps of the Patent Office of but five and eight-tenths per cent and an increase in the clerical force of but three and nine-tenths per cent and providing increases in salary for the position of primary examiners from $2700 to $3900 and of assistant examiners in proportion, and providing increases in the salaries of the clerical force only to bring them up approximately to the average corresponding salaries of other Governmental Departments and Bureaus, and as the cost of the increased salaries and force of the said Nolan Bill was more than met by an increase in the fees for patents provided therein; and

WHEREAS, the United States Senate so amended the said Nolan Bill that instead of increasing it decreases the examining corps by fifteen and seven-tenths per cent and reduces the clerical force by about one per cent below the present insufficient numbers of said examining corps and clerical force actually employed in the Patent Office, as well as reduces the salaries, both of the examining and the clerical forces, so that the total present payroll is reduced five and nine-tenths per cent, notwithstanding that the increase in fees for patents which were made to provide funds for the increased force and salaries were retained in the bill; and

WHEREAS, in the opinion of Engineering Council, the general effect of the changes in force and salaries made by the Senate would amount to a catastrophe for the Patent Office; and

WHEREAS, the salary of $3900, provided in the bill as it passed the House of Representatives, is low for the position of Principal Examiner when compared with the salaries paid by private corporations and employers for engineers having a similar grade of responsibilites and requirements—that

is, engineers required to make and assume responsibility for final decisions in important matters and to have highly technical knowledge—especially as such examiners must have both legal and technical knowledge and notwithstanding allowance for the fact that Governmental salaries are not as high as those paid by private interests; and the salaries for other grades of examiners are low in proportion;

NOW, THEREFORE, BE IT RESOLVED: That Engineering Council, representing 45,000 engineers, regards it of large importance that the numbers of the examining and clerical forces for the Patent Office and the salaries therefor in Nolan Patent Bill H. R. 11,984 be restored to those in the bill as it passed the House of Representatives; that the bill be freed from any riders, such as Section 9 thereof, which may delay or jeopardize the passage thereof, and that the bill be made a law at the earliest possible moment.

ENGINEERING COUNCIL, having on the 21st day of October, 1920, passed a resolution urging the restoration to their original values of the figures for the examining and clerical forces of the Patent Office and the salaries therefor in the Nolan Patent Office Bill H. R. 11,984, recommends that the constitutent engineering societies which it represents request their memberships to communicate with their Representatives and Senators in Congress, urging action in accordance with the said resolutions.

As the Patent Office is steadily losing more and more of its competent men and is rapidly getting farther and farther behind in its work, and as to get much farther behind would mean for it practically to cease to function, and as the bill, as amended by the Senate, is wholly inadequate to accomplish its purpose and would be worse than useless, every effort should be made to induce Congress to restore the figures of the bill to their values as passed by the House of Representatives.

The Conference Committee will probably take the bill up for consideration the middle or latter part of December. Each member of the Society is therefore most earnestly requested to write or telegraph to the member of Congress from his District to the Senators from his State and to the members of the Conference Comittee urging that the figures of the Nolan Patent Office Bill H. R. 11,984 be restored to the values which passed the House of Representatives.

It would also be well to urge that the bill be freed from any riders not related thereto, so that its early enactment will not be hindered by opposition to such riders.

The fact that letters may have already been written Senators and Representatives at an earlier stage in the passage of this bill will not serve the present emergency, because the question now is not merely the passage of the bill, but the restoration of the figures which have been so seriously cut down by the Senate.

The names of the senators and representatives can be obtained from the World Almanac, or similar publications, and from postmasters.

In connection with this bill, engineers as a class for the first time, have exerted a powerful influence in a public matter, and they should see that their work is brought to a successful conclusion.

Yours very truly

J. Parke Channing
Chairman

Committee on Patents
Edwin J. Prindle, Chairman
J. Parke Channing, Secretary
Charles A. Terry, of A. I. E. E.
Frank N. Waterman of A. I. E. E.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

NOTES OF INTEREST FROM REPORT OF NATIONAL SERVICE DEPARTMENT

For the first time since the establishment of the Washington office of Council the Congress has been in a long period of recess. A good opportunity has therefore been afforded to determine whether the Washington office is in large degree a legislative agent for engineers or whether its functions are, for the major part, of a more permanent and continuing nature. The writer is pleased to report that those engaged in the work are not sensible of any diminution in its amount since the Congrees adjourned. To the writer this is conclusive evidence that the opportunities for service through the Washington office of Council are always greater than the capacity of the office.

National Service. Requests for information and assistance received from members of the profession decreased slightly in number during July and August, but during September and the expired portion of October have exceeded all previous experience. It is of interest to note that a large proportion of these requests came from the technical schools and colleges. The subjects cover past legislation, engineering standards, selective employment and management, indictment of coal profiteers, and the procurement of public documents on many subjects.

Engineer on the Advisory Board to the Post Office Commission. It is gratifying to report that the efforts of Council to secure this appointment have met with success. Dean M. E. Cooley, a former member of Council, now occupies the position.

U. S. Board of Surveys and Maps. The success of Council's efforts to secure the creation of this Board is of record. Since Council's last meeting the organization of outside cooperating agencies has been completed and the entire program of coordination of the Government's mapping effort is now in operation.

Report of Board of Review of War Construction. At a previous meeting of Council a resolution was passed urging the printing of the report of the Board of Review by reason of its value and usefulness as an engineering document. At that time all prospect that this report would be printed had practically disappeared. It is therefore of interest to note that the report was finally printed and has received as wide distribution as the size of the edition would permit.

Federal Power Commission. When the Federal Water Power Act became a law it was the general supposition that $100,000 appropriated by the Bill for the expenses of the administration would be available. Under a decision of the Comptroller of the Treasury the only money available is the sum of $5000 to cover the salary of the Executive Secretary. All work done has been by persons assigned temporarily by the Departments of War, Interior and Agriculture. Applications for permits now number 66, with an aggregate capacity in excess of 2,000,000 horse power. The Power Commission is unable to perform its functions in anything like a satisfactory way.

Topographic Mapping. An estimate of $600,000 for topographic mapping during the next fiscal year has recently been approved. Council last year passed a resolution favorable to an appropriation of $500,000. The amount made available by Congress was $375,000. The additional $100,000 requested for the present year is to make possible achieving in some measure the program that would have been made possible had the estimate of last year been approved.

Appropriations for Research Work. Large increases in estimates will be submitted by the various Bureaus, especially by the Bureau of Standards, so that they can increase activities in their fields and make their work more effective along technical and industrial lines.

National Department of Public Works. Resumption of legislative effort in support of a National Department of Public Works will take place prior to the next meeting of Council. It therefore appears advisable to make a rather complete report on the progress of that movement.

Country-Wide Movement for Government Reorganization. The fundamental arguments for a department of public works apply with equal force to the entire Government organization. There has grown in a short space of time a country-wide movement for Government reorganization. It is a part of the platform of one of the great political parties. It was frequently mentioned and advocated in the speeches of the several candidates, and was the text for many a campaign speech and newspaper or magazine article. The National Education Association, the Women Voter's League and the Federation of Women's Clubs, are supporting a proposed department of education. The American Public Health Association and other organizations in the realm of sanitation and preventative medicine are supporting a department of health. Certain welfare organizations are advocating a department of public welfare; there is also a movement for a department of aeronautics; and an old movement for a department of mines still exists. The National Budget Committee, having practically completed its labors in behalf of a budget system of Federal finance, is actively turning its attention to the entire field of Federal reorganization.

The National Budget Committee, the Public Works Department Association, and the National Education Association are participating in the activities of what is known as the National Committee for Governmental Economy, the purpose of which is to make and report upon a complete study for governmental reorganization. The report is practically completed.

In all of these organizations, with possibly one exception, the creation of a department of public works is an accepted doctrine. Opposition exists in some of the organizations to the purposes of some others, but all unite in favoring a public works program, and the most favorable feature of this is the general agreement that the department of public works should be created not through the creation of an additional Cabinet office but by a readjustment of the agencies already existing. It is the other new departments therefore that will have to carry the heavy legislative burden of overcoming the opposition to enlargement of the Cabinet.

Possibility of Amalgamating all Reorganization. Early in October there was a meeting in New York City, attended by Mr. John T. Pratt, head of the National Budget Committee; Mr. Herbert Hoover; Mr. Henry L. Stimpson, former Secretary of War; Mr. Paul Warburg; Major C. T. Chenery, and the writer (M. O. Leighton), at which matters of Government reorganization were discussed, and particularly the need for and the possibility of amalgamating all reorganization efforts under a commonly accepted and supported program. It was brought out that if many organizations conduct campaigns separately, each for its own particular project, the confusion created in Congress will probably result in no legislation. It was therefore decided to call a meeting of delegates from the several organizations advocating reform in the Government departments, to organize a Federal Reorganization Council, which would be the common body through which an accepted program would be carried forward.

The aforesaid meeting of such delegates was held in New York on October 14th, at which time the nearly completed report of the National Committee on Governmental Economy was presented. That program provided for a general rearrangement of Government activities along functional lines, including the creation of a department of public works by a reorganization of the present Interior Department, and an additional department to be called the Department of Education and Health, into which would be drawn such welfare activities as war risk insurance, vocation and rehabilitation, pensions, etc. The meeting for final organization was scheduled to take place about November 15th. The prospective field of such a council is not limited to the mere reorganization of Federal activities. It should become the authoritative unofficial body to engage in the work which will eventually lead to a distinct separation of the political features of our Government system from the conduct of departmental business.

There is also being discussed the consolidation of the Public Works Association with the National Budget Committee. This move appears to be wise from the standpoint of efficiency and economy. Inasmuch as the Budget Committee has adopted the public works principle the two organizations if separately sustained will largely duplicate each other's efforts.

To summarize as to the prospects for a department of public works: It is the writer's belief that the principle is thoroughly settled in the minds of the public and of a majority of the members of Congress.

PERSONAL MENTION

C. D. Young succeeds Albert Ladd Colby, resigned, as representative of the American Society for Testing Materials on Engineering Council.

Major James R. Werth has been appointed Commercial Service Manager of the West Penn Power Company with offices at West Penn Building, 14 Wood Street, Pittsburgh, Pa.

S. N. Dalal, who was assistant superintendent in the electrical workshop, College of Engineering, at Poona, India, has left that post to become superintendent of stores and workshop, Royal Institute of Science, Bombay.

G. L. Hoadley, formerly head of the Department of Electricity, American School of Correspondence, Chicago, has accepted the position of associate professor of Electrical Engineering at the Washington State College, Pullman, Washington.

Charles E. Burgoon has resigned from the position of staff assistant, in charge of appraisals, to the Director of Supply & Sales, United States Shipping Board Emergency Fleet Corporation, Washington D. C., to accept the position of Property and Records Engineer with the Cuba Cane Sugar Corporation, Havana, Cuba.

R. F. Hayward, formerly general manager of the Western Canada Power Company, Ltd., Vancouver, B. C., has relinquished this office to become general manager of the Chilian Electric Tramway & Light Company, Ltd., Santiago, Chile. He left the United States in November to take up his new duties. Mr. Hayward expects still to be able to keep up his interest in A. I. E. E. affairs, though at such a great distance.

H. H. Barnes, Jr., district engineer of the General Electric Company in New York, has been appointed assistant district manager. Mr. Barnes is a very active member of the Institute, acting as chairman of the Law Committee and the Special Committee of Geographical Division and Election Procedure. He is also a member of the Edison Medal Committee and is on the Board of Trustees of the United Engineering Society.

L. W. Chubb, of the Westinghouse Electric & Manufacturing Company, has been appointed manager of the company's new Radio Engineering Department. Mr. Chubb is known to many members of the Institute by his interest in its activities,

having served for a number of years on various committees; at present he is a member of the Meetings and Papers Committee Standards Committee, Electrophysics Committee, and the United States Committee of the International Electrotechnical Commission. He ha sbeen with the Westinghouse company for the past fifteen years, in both research and practical work.

Dr. E. F. Northrup, who resigned his professorship at Princeton University to devote his attention to the newly-formed Ajax Electrothermic Corporation, of Trenton, N. J., is now vice-president and technical advisor of that company. The company as incorporated is controlled by the Ajax Metal Company of Philadelphia, from which it takes over the Northrup furnace patents. It takes over also the manufacture and sale of the Ajax-Northrup high-frequency induction furnace from the Pyroelectric Instrument Company of Trenton, of which Dr. Northrup was formerly president.

E. C. Morse, Director of Sales, War Department, Washington, D. C., has tendered his resignation to the War Department, effective December 31, or earlier. Mr. Morse went to Washington during the early days of the war as representative of the Westinghouse Electric & Manufacturing Company, but was soon induced to enter the Government service in the Purchase Branch of the Construction Division of the Army. He remained with that organization until the Office of the Director of Sales was organized for the purpose of disposing of surplus Army supplies, when he was made Assistant Director of Sales in January, 1919, later becoming Director of Sales. He will return to civil life, but has not yet decided upon the line of work he will follow.

OBITUARY

Oscar Hansen, an Associate of the Institute, died on October 31, 1920. Mr. Hansen was born in Kenosha, Wisconsin, May 15, 1872; he received his early education in Kenosha and later finished the course in electrical engineering at the University of Wisconsin. He had been employed at various times by the Western Electric Company, Gibbs Brothers of Milwaukee, Wis., the Chicago Telephone Company, The Sanitary District of Chicago, and at the time of his death was an electrical engineer for the City of Chicago.

Angus Kenneth Miller, Engineer of Substation Construction with the New York Municipal Railway Corporation, Brooklyn, N. Y., died November 1, 1920, at Saranac Lake, N. Y. Born at Bridgsburg, Canada, December 1, 1879, Mr. Miller received his technical education at McGill University, Montreal. He had been with the Westinghouse Electric & Manufacturing Company for about five years before entering the employment of the Brooklyn Rapid Transit Company. He became an Associate of the A. I. E. E. in 1907.

Henry Hovelson, an Associate of the Institute, died on May 28, 1920, of appendicitis, at St. Barnabas Hospital, Minneapolis. Mr. Hovelson was born in Minneapolis, February 1, 1881. He completed the electrical engineering course at the University of Minnesota in 1908, after which he was engaged with various engineering concerns in electrical construction and design. At the time of his death he was connected with the Marshall-Wells Company, of Duluth, as Engineer and Estimator. He became ill in Duluth the latter part of April, and left then for Minneapolis, which had been his home the greater part of his life. Mr. Hovelson joined the Insttute in 1916.

Charles Ernest Acker died at his home at Ossining, N. Y., on October 18, 1920. Mr. Acker, manufacturer and inventor, had received the Elliot-Cresson gold medal of the Franklin Institute and several other medals for his development of the first electrolytic process for the manufacture of caustic soda by the electrolysis of molten salt, known as the Acker process. He was born at Bourbon, Ind., March 19, 1868, and was educated at Wabash College and Cornell University. From 1888 to 1893 he was engaged in electrical engineering work in Chicago, but after that time turned his attention to chemistry and electrochemistry. He built the works of the Acker Process Company, at Niagara Falls, originated processes for the manufacture of tetrachloride of tin and carbon tetrachloride and was the first to manufacture carbon tetrachloride in America. Mr. Acker was a director of the American Electrochemical Society; a member of the Society of Arts, London; Faraday Society, London; American Chemical Society; Society of Chemical Industry; Chemists' Club; and the Institute, which he joined as Associate in 1903.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

CATALOGING OF THE LIBRARY

The Engineering Societies Library of today has for its ancestors four separate libraries which began at different periods, were developed in different ways and with varying ideals, and had not attained the same degrees of development when they were combined. The methods of classifying the books and of cataloging them in use in the separate libraries were so dissimilar that a revision of all this work was essential if members were to use the collection conveniently, and with any assurance that all the material available had been found.

The Library Board, as announced in its report published in the March, 1920, Journal, decided early in 1919, to undertake the recataloging of all the material. As no uniform scheme for classifying the books was in use, much reclassification is also involved. A special corps of workers was assembled for the task and since the fall of 1919, the energies of the staff have been chiefly concentrated on this work.

As it is believed that the methods adopted will not only fix the practise of the Library for years to come, but may also become the standard for other engineering collections, every

effort has been made to adopt methods that will both meet present needs and also provide for future developments, so far as these can be predicted. This has involved the sacrifice of speed, but as the work is intended to be permanent, basic soundness has been considered the prime quality.

At present, approximately one-fourth of the work is done. The recataloged material includes all the publications of the past four years, and those classes of the older material most in use; among others, the periodicals, and the geological material for many states. Work on the remaining material is proceeding class by class, the most important classes being treated first.

The following extracts from a report submitted in October by Miss Margaret Mann, the Chief Cataloger, give detailed information on certain phases of the problem. They will, it is hoped, be of interest to many members, as showing the results obtained, the difficulties to be overcome and the results anticipated when the work is finished.

Extracts From Report

The Chief Cataloger came to the Library May 1, 1919 and after devoting one month of study to the problem, began the search for a staff of assistants. The staff was accumulated gradually. Real work did not begin until September, 1919.

During the year from September, 1919 to October, 1920, 23,204 books have been completely cataloged and 31,679 volumes have been handled in order to catalog these 23,204. The 23,204 volumes represent 5,000 titles.

This has been accomplished with a staff averaging ten.

Some Interesting Statistics

Volumes	
New volumes cataloged	2,194
Old volumes recataloged	21,010
Volumes added to existing records	2,499
Duplicate volumes listed	4,676
Volumes withdrawn from the Library	1,300
Total volumes handled	31,679
Additions to the New Catalog	
Titles represented	5,000
Subjects "	10,301
Catalog cards added	26,637
Index	9,052
Cards	
Cards Typed	43,024
Library of Congress cards used	10,769
Total cards filed in official and public catalogs	53,793

Summary

23,204 volumes represent 5,000 titles. From these 5,000 titles we have made available 10,301 subjects. To catalog 23,204 volumes, or 5,000 titles, completely by author and subject, we have had to handle 31,679 volumes, which has necessitated the preparation and filing of 53,793 cards and the typing and filing of 840 sheets into loose-leaf binders.

The Results to be Gained by Recataloging

1. *Making the resources of the Library available.*

By the recataloging the varying methods of cataloging and classifying formerly used by the societies are being eliminated, bringing the collection together into a logical whole.

Much of the material handled by the cataloging staff this year cannot be called recataloging, because many classes of books now in the Library have not, up to this time, been represented in the catalog.

Such difficult work as the cataloging of the State and Federal documents is quite new to this Library. Some of the most valuable material covering such subjects as Mining, Geology, Foreign Trade, Water Supply, Road Engineering, etc., is to be found in the reports and bulletins issued by State surveys, commissions and experiment stations.

Publications emanating from the various Bureaus are being analyzed and made available for the first time.

2. *The Library will have a catalog,* which can be printed in small but complete units, small enough to be included in our own society journals.

Unlike an alphabetical catalog the classified catalog now in process of making can be used and printed by subject. It is so arranged that one class such as Hydraulic engineering is complete in itself and is not scattered under Pumps, Dams, Water flow, etc. An alphabetical index takes care of Pumps, Dams and Water flow, while the whole class of Hydraulic engineering remains as a unit.

Should a smaller class be needed, such as Dams, this will also be found to be a complete unit.

3. *Weak spots in the collection* will be revealed and records furnished for filling in the gap.

Until the books are combined under one classification it is quite impossible to see wherein the Library is weak.

4. *The catalog will establish a system of classifying engineering literature* which can be applied not only to books but also to the indexing of periodicals.

5. *We will have compiled an alphabetical key* to the classification which, if published, will enable any engineer to index his own library, and his own periodicals, by the most approved international method at a minimum cost.

This has never before been accomplished by any library or any individual and its completion will see a real contribution to engineering literature. It is an aid which engineers are seeking.

The possibilities for completing the work seem most hopeful. This year can only be called preparatory to what we should accomplish later on. We have had to lay our plans, build the foundations and train our staff. The succeeding months should show a steady increase in our output and a greater ease in our accomplishment of results.

The cooperation offered on all sides has helped to lighten the burden and keep up our courage.

The cataloging staff have given faithful service during a very difficult year.

BOOK NOTICES (FROM OCTOBER 1 to 31 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or text of the book.

All books listed may be consulted in the Engineering Societies Library.

The Chemical Analysis of Steel-Works' Materials.

By Fred Ibbotson. Lond. & N. Y., Longmans, Green & Co. 1920. 296 pp., tables, 9 x 6 in., cloth $7.50.

This work is a revised edition of those portions of The Analysis of Steel-Works' Materials, published in 1902, which treated of the analytical chemistry of the raw materials and finished products of ferrous metallurgy. The material on pyrometry and microscopy is omitted from the revised book.

The Coal Trade.

The Year Book of the Coal and Coke Industry. By Sydney A. Hale. 47th annual edition, 1920. N. Y., The Estate of F. E. Saward, 352 pp., tables, 8 x 6 in., cloth, $4.

The present volume is, the compiler states, the largest in size and the widest in scope yet issued. It includes a variety of statistical tables of interest to those in the coal industry, brought to the latest possible dates, and information showing the development of the industry during the past year. The book contains statistics of production, exports, imports, costs, prices, ocean rates, wages and similar matter, as well as reviews of important occurrences.

Common Sense and Labor.

By Samuel Crowther. Garden City, N. Y., Doubleday, Page & Co., 1920. 284 pp., 8 x 5 in., cloth, $2.

The author discusses the cause of present day dissatisfaction between workmen and employers, the various remedies that have been suggested, and the results obtained in actual cases. Written in readable style, and of interest to employers.

Condensed Catalog of Mechanical Equipment.

Comprising Condensed, Uniformly Presented and Illustrated Catalog Information Covering the Products of Manufacturers of Various Classes of Mechanical Equipment, with General Classified Directory . . .and Consulting Engineers' Directory. Tenth annual volume, October 1920. N. Y., American Society of Mechanical Engineers, 1004 pp., illus., 9 x 6 in., cloth $4.

The tenth edition of this catalog and directory of mechanical equipment and consulting engineers follows the established lines although the data on A. S. M. E. standards have been omitted from this issue. Five hundred and nine firms are represented by condensed catalogs of their products, this section being eighty pages longer than in 1919. The directory of mechanical equipment, in which manufacturers are listed under products, is 10 per cent larger, and the directory of consulting engineers covers 60 per cent more pages than before. Various improvements have also been made to facilitate convenient reference.

ELEMENTS OF ENGINEERING THERMODYNAMICS.

By James A. Moyer, James P. Calderwood and Andrey A. Potter. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 216 pp., illus., tables, folded chart, 9 x 6 in., cloth, $2.50.

This treatise is an extension of a briefer work entitled "Engineering Thermodynamics", by James A. Moyer and F. A. Calderwood. It is intended to bring out the fundamental principles of the subject, particularly for use in technical college where special courses on steam turbines, internal combustion engines, refrigeration and other applications of thermodynamics can be given.

Additions and changes have been made to the original material, to make the book better adapted to special requirements.

ENGINEERING ELECTRICITY.

By Ralph G. Hudson. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall Ltd., 1920. 190 pp., illus., tables, 9 x 12 in., cloth $2.50.

This text represents the lectures given at the Massachusetts Institute of Technology to those technical students who are not specializing in electrical engineering. The course covers the general principles of electrical engineering and magnetism most frequently applied in engineering practise.

FINANCIAL ENGINEERING.

A Text for Consulting, Managing and Designing Engineers and for Students. By O. B. Goldman. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 271 pp., illus., tables, 9 x6 in., cloth, $3.50.

Contents: Cost Segregation; Fundamental Financial Calculations; Basic Costs; Vestances; Unit Cost Determination; Determination of Size of System for Best Financial Efficiency; Determination of Type and Size of Units.

The author of this treatise has in mind the practising engineer, interested in installing plants that will have the highest financial efficiency, although not necessarily the highest mechanical efficiency. The book is therefore an exposition of methods for determining the comparative value of the things which the engineer must use, and the financial efficiency of undertakings.

THE IRON ORES OF LAKE SUPERIOR.

Containing Some Facts of Interest Relating to Mining and Shipping of the Ore and Location of Principle Mines. Fourth edition, with original maps of the ranges. By Crowell & Murray. Cleveland, The Penton Press, 1920. 301 pp., illus., maps, tables, 9 x 6 in., cloth, $5.

This is a concise account of the development and present status of the mining properties of the Lake Superior region and of the iron mining industry in general. The introductory chapters treat of the early history of the region, its geology and mineralogy, and the methods of drilling, exploring, mining and analyzing the ores, accompanied by extensive records of the average analysis of the various ores and a chapter on their valuation. The remaining and larger portion of the book is given to brief descriptions of the individual mines, accompanied by sketch maps of each range.

THE LOCOMOTIVE UP TO DATE.

By Chas. McShane. Revised by the author. Chic., Griffin & Winters, 1920. 893 pp., illus., plates, 9 x 6 in., cloth $5.

The first edition of this book appeared over twenty years ago, and found popularity as a clear explanation of the construction, operation and repair of the locomotive, suited to the needs of railway men without special engineering knowledge. The present edition has been revised, enlarged, and partly rewritten, to meet modern conditions.

MINE GASES AND VENTILATION.

Textbook for Students of Mining, Mining Engineers and Candidates Preparing for Mining Examinations, Designed for Working out the Various Problems that Arise in the Practise of Coal Mining, as They Relate to the Safe and Efficient Operation of Mines. By James T. Beard. Second edition revised and enlarged. N. Y., & Lond., McGraw-Hill Book Co., Inc., 1920. 433 pp., illus., plates, tables, 8 x 6 in., flexible cloth, $4.00.

The present edition of this treatise on mine ventilation has been much enlarged. New Sections on Safety Lamps, Oils, Breathing Apparatus and Rescue Work have been added, together with numerous tables. The endeavor has been to make the book a standard work on the subject.

MINERALOGY.

An Introduction to the Study of Minerals and Crystals. By Edward Henry Kraus and Walter Fred Hunt. First edition. N. Y. & Lond., McGraw-Hill Book Co., Inc., 1920. 561 pp., illus., 9 x 6 in., cloth, $4.50.

The aim of the authors of this work has been to present in a direct, simple manner, and within a single volume, the essentials of the various phases of the science. The conventional line drawings of crystals have been largely replaced by photographs of models, natural crystals and minerals, such as are actually handled in the laboratory. An attempt has also been made to vitalize the subject by including chapters on the importance of mineralogy, on gems and precious stones, and on the production and uses of the important economic minerals. Numerous photographs and short sketches of noted mineralogists have been added. The book treats of crystallography, blowpipe analysis and descriptive mineralogy, and has determinative tables.

FUNDAMENTAL PRINCIPLES OF ELECTRIC AND MAGNETIC CIRCUITS.

By Fred Alan Fish. First edition. N. Y. & Lond., McGraw-Hill Book Co., 1920. 194 pp., illus., 9 x 6 in., cloth $2.75.

This volume is intended as an introduction to the study of electric power machinery and transmission. It discusses the principles that the author considers fundamental, is intended for undergraduate students, and therefore does not go deeply into the physical and mathematical theory of electricity, nor include all the possible variations in conditions which might affect the application of the principles as stated.

GEOLOGY OF THE NON-METALLIC MINERAL DEPOSITS OTHER THAN SILICATES.

Vol. I. Principles of Salt Deposition. By Amadeus W. Grabau. First edition. N. Y. & Lond., McGraw-Hill Book Co., Inc., 1920. 435 pp., illus., maps, tables, 9 x 6 in., cloth, $5.00.

This book, the author states, is essentially a treatise on applied stratigraphy. It deals with non-metallic mineral deposits exclusive of silicates, but with merely incidental consideration of hydrocarbons and some native elements, which will be treated more fully later. It may be called a handbook of salt geology, if this name is understood to include nitrates, borates, phosphates and similar deposits. Emphasis is laid upon the geological relationships of these deposits and the conditions under which such deposits form are studied.

INDUSTRIAL HOUSING.

With Discussion of Accompanying Activities; Such as Town Planning—Street Systems—Development of Utility Services—and Related Engineering and Construction Features. By Morris Knowles. First edition, N. Y. & Lond., McGraw-Hill Book Co., Inc., 1920. 408 pp., illus., tables, 9 x 6 in., cloth, $5.00.

The author endeavors to develop the things which must be considered in order to provide not merely houses but homes, with all the attendant attributes of a living and livable town, and his book is the result of a realization that the preparation of a successful town plan and the development of a contented industrial community are dependent upon the action of many agencies and require the coordination of men of many professions. Although the work of an engineer, the book is not a treatise on technical practise, but is intended to represent the views of experts in architecture, town planning, landscape gardening, engineering, sanitation, public utilities, building, real estate, civics and business, for whom, together with city officials, the book is intended.

MODERN PULP AND PAPER MAKING.

A Practical Treatise. By G. S. Witham, Sr. N. Y., Book Dept. The Chemical Catalog Co., Inc., 1920. 599 pp., illus., 9 x6 in., cloth, $6.

This treatise is the work of a writer with long practical experience in the industry, and is intended to fill the need for a practical work on paper manufacture as carried on in America,

that is not too abstruse and technical for the average papermaker, but which is thorough enough to be of real value. The book describes the equipment and processes in actual use, and also treats of plant design and personnel.

A Practical Treatise on Engineering and Building Foundations including Sub-aqueous Foundations.

Vol. I. Ordinary Foundations. By Charles Evans Fowler. Fourth edition. N. Y., John Wiley & Sons, Inc.: Lond., Chapman & Hall, Ltd., 1920. 531 pp., illus., plates, tables, 9 x 6 in., cloth, $5.

The present treatise, which will include three volumes when completed, is a revision and expansion of the author's former book entitled "Sub-aqueous Foundations." Much has been added on the masonry of retaining walls, abutments, bridge piers and other classes of engineering foundations, including foundations for buildings. Volume one is a comprehensive treatment of ordinary foundations, covering piles, pile driving, the masonry of retaining walls, abutments and bridge piers. Volume two will treat of caissons and deep foundations generally, building foundations, underpinning, and foundations for dams, sea walls, drydocks and locks. Volume three will cover the design and construction of harbors.

The Practise of Lubrication.

An Engineering Treatise on the Origin, Nature and Testing of Lubricants, their Selection, Application and Use. By T. C. Thomsen. First edition, N. Y. & Lond., McGraw-Hill Book Co., 1920. 607 pp., illus., 9 x 6 in., cloth.

After a brief, practical description of commercial oils, fats and greases, the author describes the chemical and mechanical tests used and explains the laws of friction. Methods of lubrication are then described. The greater portion of the book is given to a discussion of the selection and use of lubricants for specific types of machinery, covering all classes of machines. Oil recovery, purification, storage and distribution, oils for cutting and for transfomers are also discussed. The viewpoint throughout is that of the engineer rather than the chemist.

Tin, Sheet-Iron and Copper-Plate Worker.

By Leroy J. Blinn. New enlarged edition. N. Y., Henry Carey Baird & Co.. Inc., 1920. 334 pp., illus., tables, 8 x 5 in., cloth, $3.

A revised edition of a well-known work on the working of sheet-metal, containing rules for laying out work, recipes for solders, cements, and lacquers, as well as the tables and other data used by the mechanic.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Atlanta.—October 29, 1920. Business meeting, followed by presentation of an interesting moving picture of the Georgia Railway and Power Company's hydroelectric development on Tallulah River. After the meeting adjourned refreshments were served by the Entertainment Committee. Attendance 30.

Baltimore.—October 15, 1920, Lexington Street Building. Mr. Herbert A. Wagner, President, Consolidated Gas, Electric Light and Power Company, gave an introductory talk on the progress of "Modern Illumination," followed by an illustrated lecture on "Methods of Industrial Lighting," by Mr. Ward Harrison, of the National Lamp Works, Cleveland, Ohio. The meeting ended with the serving of light refreshments through the courtesy of the Consolidated Gas, Electric Light and Power Company. Attendance 100.

Chicago.—October 20, 1920. Fullerton Hall, Art Institute. Subject: "Origin and Energy of the Lightning Flash." Speaker Dr. C. P. Steinmetz. Attendance 500.

Cincinnati.—October 14, 1920. Assembly Hall, Union Gas & Electric Company. Subject: "Time and Space in terms of Einstein's Theory of Relativity." Speaker: Dr. Saul Dushman of the Research Laboratory of the General Electric Company. Attendance 58.

November 11, 1920. Assembly Hall, Union Gas & Electric Company. Subject: "Automatic Substation Equipment." Speaker: Mr. C. A. Butcher of the Westinghouse Elec. & Mfg. Co. Attendance 45.

Cleveland.—October 19, 1920. Subject: "Telephone Service for Cleveland." Speaker: Mr. Charles P. Cooper. Attendance 112.

Denver.—October 16, 1920. Metropole Hotel. After the usual dinner the Chairman opened the meeting with the announcement of committee appointments. The speaker of the evening was Mr. M. G. Brannan of the Riley Underfeed Stoker Co., on the subject of: "Stokers and Their Application." Attendance 40.

Detroit-Ann Arbor.—October 8, 1920. Board of Commerce. First dinner and meeting of the season. The general object of the meeting was to get the members of the section acquainted with each other and to secure their opinion as to ways and means of increasing the value of the section to its members. Attendance 80.

October 22, 1920, Board of Commerce. Round table talk. Subject: "Characteristics and Applications of Transformers." The discussion was led by Professor Parker. Attendance 45.

Ithaca.—October 29, 1920. Franklin Hall, Cornell University. Speakers: Professor V. Karapetoff on "High Spots in the A. I. E. E. 1920 Convention"; and Dr. Edw. L. Nichols on "Personal Recollections of Oersted and Ampere 1820." Attendance 102.

Lynn.—November 3, 1920. Subject: "Problems Involved in Large Generating Stations." Speakers: Messrs. Probst, Sittinger, Mars and Schiller. Attendance 180.

Philadelphia.—November 8, 1920. Engineers' Club of Philadelphia. Subject: "Recent Progress in Radio Telephony.". Speaker: Dr. H. W. Nichols, Research Engineer in Charge of Radio Research, Western Electric Company. Attendance 146.

Pittsburgh.—October 12, 1920. Auditorium, Chamber of Commerce Building. Subject: "Induction-Motor Core Losses" (paper by P. L. Alger and R. Eksergian). Speaker: Mr. P. L. Alger. Attendance 85.

Portland, Ore.—September 28, 1920. University Club. Subjects: "Actual Accomplishments of the California Cooperative Campaign," by Miss Clotilde Grunsky, E. E., and "The Origin and Purpose of the Northwest Electric Service League," by Mr. A. C. McMicken. Attendance 75.

October 19, 1920. University Club. Paper: "Scientific Illumination and its Practical Application." Speaker: Mr. F. H. Murphy, Illumination Engineer, Portland Railway, Light and Power Company. Attendance 80.

Providence.—November 2, 1920. Providence Engineering Society. Joint meeting with the Power Section of the Providence Engineering Society. Subject: "Public Utility Rate Making." Speaker: Mr. Jesse E. Gray, Assistant Secretary of the Narragansett Electric Lighting Company. Attendance 45.

Schenectady.—October 15, 1920. Edison Club Hall. Subject: "Some Ice Problems and Their Solutions." Speaker: Mr. John Murphy, Department of Railways & Canals, Ottawa, Ontario, Canada. Mr. Murphy divided his subject into two parts—first, ice conditions as they are, with pictures illustrating actual conditions and moving pictures showing how frazil and anchor ice are formed; second, methods for preventing ice in waterwheels, forebays and penstocks, illustrated with pictures. Attendance 275.

Seattle.—October 19, 1920. Arctic Club Assembly. Subject: "The Power Indicating and Limiting System in Use on the

Western Division of the Chicago, Milwaukee & St. Paul Railway." Speaker: Mr. C. Anderson, of the Westinghouse Electric & Mfg. Company. Attendance 80.

Spokane.—October 21, 1920. Davenport Hotel. Dinner followed by joint meeting with Associated Engineers. Subject: "Industrial Research." Speaker: Dr. C. E. Magnusson. Attendance 22.

Syracuse.—October 8, 1920. Technology Club. Organization meeting and election of officers as follows: Chairman, Edward T. Moore; Secretary, Frank Simpson.

Toronto.—October 15, 1920. Chemistry Building, Toronto University. Subject: "The Manufacture of Electrical Wires and Cables." Speaker: Mr. H. P. Young, Chief Engineer, Canada Wire & Cable Co. Attendance 88.

October 29, 1920. Toronto University. Subject: "High-Frequency Multiplex Telephony." Speaker: Dr. Chas. R. Culver, of the General Engineering & Construction Co., Ltd. Attendance 134.

November 10, 1920. Hart House, University of Toronto. Social meeting, including moving pictures, music, a mathematical contest, short speeches by several members of the section, and refreshments. Attendance 117.

Utah.—October 15, 1920. Commercial Club. Mr. H. T. Plumb, official delegate to the Annual Convention, presented an interesting paper on "The Outstanding Features of the 1920 Convention." The paper was divided into three parts: (1)Institute Affairs, (2) Impressions of Delegates, (3) Technical Papers. Attendance 20.

Vancouver.—September 24, 1920. Committee appointments. Mr. R. F. Hayward reported his impressions of the Portland Convention in July and briefly discussed the papers presented there. Attendance 21.

Washington.—October 12, 1920. Cosmos Club, Washington, D. C. Dr. F. A. Wolff of the Bureau of Standards gave an illustrated lecture on "Functionalized Circuit Diagrams." Following this Mr. Walter E. Brown of the Telephone Section of the Bureau of Standards, gave an illustrated talk on "Telephone Service." Attendance 74.

PAST BRANCH MEETINGS

University of Arkansas.—October 5, 1920. Engineering Hall. Business meeting. Subjects discussed: "Things an Engineer Should Know," by Professor Ripley; "The Electrification of the Chicago, Milwaukee, and St. Paul Railroad." by P. L. Mardis of the Westinghouse Elec. & Mfg. Co. Attendance 40.

November 2, 1920. Engineering Hall. Subject: "The Construction of High-Tension Transmission Lines." Speaker: R. P. Hart. Attendance 14.

University of California.—October 20, 1920. Subject: "Individual Drive as Applied to Machine Tools and the Advantages of Motor-Generator Sets and D-C. Equipment." Speaker: Mr. F. L. Boissonault of the Westinghouse Elec. & Mfg. Co. Attendance 28.

November 3, 1920. Subject: "The Financing of Public Utilities." Speaker: Dean Hatfield. Attendance 34.

California Institute of Technology.—October 26, 1920. Election of officers as follows: Chairman, Ray W. Preston; Secretary, Lawrence F. Chandler. Attendance 14.

University of Cincinnati.—October 12, 1920. Engineering Building. Professor C. B. Hoffmann gave an informal talk on the A. I. E. E. work at U of C. Attendance 82.

October 19, 1920. Engineering Building. Subject: "What 'Convenience Outlets' Mean to the Trade and Power Company." Speaker: Mr. L. T. Milnor, President of the Milnor Elec. Co., of Cincinnati. Attendance 87.

October 26, 1920. Engineering Building. Subject: "What We Mean by Electric Service." Speaker: Mr. W. W. Freeman, President of the Union Gas & Elec. Co. Attendance 87.

Clemson Agricultural College.—October 12, 1920. Subject: "Recent Electrical Developments." Speaker: Professor F. T. Dargan. Attendance 99.

November 9, 1920. Subjects: "Hydroelectric Power," by Messrs. Moore and Gower; "The Hundredth Anniversary of Electromagnetics," by G. M. Riley. Attendance 50.

University of Colorado.—October 14, 1920. Engineering Building I. Election of officers as follows: Chairman. T. H. Clarke; Secretary, C. L. Kerr; Treasurer, W. F. Suess. Attendance 37.

University of Iowa.—November 1, 1920. Physics Building. Election of officers as follows: Chairman, W. C. Reilly; Vice-Chairman, R. K. Klatt; Secretary-Treasurer, A. Schump. Attendance 30.

University of Kansas.—October 6, 1920. Marvin Hall, K. U. Subject: "The purposes of the A. I. E. E. Association and its Meaning to Electrical Engineers." Speaker: Professor Shaad. Attendance 90.

October 20, 1920. Marvin Hall. Meeting of the different engineering societies. Lecture on "Concrete" was given.

Kansas State Agricultural College.—October 7, 1920. Addresses by Professor Reid and President Joss. Mr. G. W. Fisher spoke on "A Summer's Experience with the General Electric Company." Attendance 115.

October 15, 1920. Subjects: "Two Summers' Experience with the Long Lines Department of the American Telephone & Telegraph Company," by R. S. Breese; "A Summer's Experience with the Commonwealth Edison Company of Chicago," by M. J. Lucas; extemporaneous talk on the General Electric Company, by C. F. Joss. Attendance 126.

Lehigh University.—October 21, 1920. Paper: "The Electron Theory of Electricity." Speaker: Professor S. S. Seyfert. Attendance 77.

University of Maine.—October 27, 1920. Lord Hall. Subjects: "Work with the American Telephone Company," by Ralph M. Kendall; "Illumination," by Professor W. E. Barrows. Attendance 24.

Massachusetts Institute of Technology.—November 4, 1920. Subject: "Electrical Public Utilities Operation." Speaker: Mr. L. L. Elden, Boston Edison Company. Attendance 53.

Michigan Agricultural College.—October 21, 1920. Professor A. R. Sawyer gave a short talk concerning the foundation of the student branches and their relationship to the Institute. Professor L. S. Foltz also gave a very interesting talk on "Testing of Rail Bonds." Attendance 47.

November 9, 1920. Mr. R. D. Wyckoff presented the theory and operation of the oscillograph in a most interesting manner. The lecture was supplemented by many sketches and diagrams and was followed by an actual demonstration of the "Duddell Oscillograph." Attendance 54.

School of Engineering of Milwaukee.—October 16, 1920. Mr. A. W. Berresford, President of the A. I. E. E., gave a very interesting talk on "The Ideals of the Institute." Mr. H. W. Cheney, Chairman of the Milwaukee Section of the Institute, delivered a short talk on the aim and purpose of the Milwaukee Section. Mr. A. Simmon, of the Cutler-Hammer Mfg. Co., gave a short address pointing out the progress of the School of Engineering Branch and the advantages of such an organization to students. Attendance 154.

University of Minnesota.—October 29, 1920. Election of officers as follows: Chairman, Basil C. Maine; Secretary, Ludvig C. Larson; Treasurer, A. W. Wilson. Attendance 30.

University of Missouri.—October 18, 1920. Engineering Building. Subject: "The Application of Electricity to Marine Engineering." Speaker: Mr. R. A. Beekman, of the General Electric Company. Attendance 115.

University of Nebraska.—November 3, 1920. E. E. Building. Subject: "District Steam Heating." Speaker: Mr. I. B. Starr of the Lincoln Traction Co. Attendance 28.

North Carolina State College.—October 5, 1920. Business Meeting. Attendance 24. Paper: "The Electromagnet." Authors: Messrs. Guirkin, Wallace and Inscoe. Attendance 44.

October 19, 1920. Mr. Mann gave a talk on the proposed features of the Electrical Show. Capt. Cox spoke of the benefits derived from being members of the A. I. E. E. Attendance 30.

Ohio Northern University.—October 20, 1920. Dukes Memorial. Subjects: "Value of Laboratory Work to an Engineer," by Professor F. L. Berger; "Oscillograph Demonstration," by Professor F. W. Molitor. Attendance 51.

Ohio State University.—October 28, 1920. Subject: "Electrical Power and Steam Power." Speaker Dean Hitchcock. Attendance 27.

University of Oklahoma.—October 7, 1920. Engineering Building. Business meeting. Attendance 34.

Oklahoma Agricultural and Mechanical College.—November 4, 1920. Subjects: "Electrical Possibilities in South America," by Mr. Walter Rey; "The Importance of Electrical Engineering in Foreign Markets," by Mr. Edward Sadlor; "Installation of Electrical Mine Hoists in South Africa," by Mr. G. C. Wells. Attendance 18.

University of Pennsylvania.—October 13, 1920. Engineering Building. Business meeting; committee appointments. Attendance 42.

Pennsylvania State College.—November 11, 1920. Subject: "The Engineer in Big Business." Speaker: R. L. Sackett. Attendance 50.

Purdue University.—October 19, 1920. Subjects: "Sound Ranging in the World War," by Professor L. D. Rowell; "History of the Purdue Union Movement," by Dean Coulter. A movie comedy was also shown. Attendance 95.

Stanford University.—October 7, 1920. Business meeting. Attendance 13.

Syracuse University.—October 5, 1920. Election of officers as follows: Chairman, Floyd C. Barnes; Secretary, Florent E. Verdin. Attendance 14.

October 12, 1920. Paper: "Electrical Equipment for Locomotives." Author: Mr. Wilson. Attendance 13.

October 19, 1920. Subject: "Distribution System of Syracuse Lighting Company." Speaker: Mr. Smith. Attendance 13.

University of Virginia.—October 14, 1920. Subjects: "The Purpose and Advantages of being a Student Member," by Professor W. S. Rodman; "My Experiences with the Appalachian Power Company as a Maintenance Man," by W. T. Straley; "Taking Data on Connected Loads," by H. M. Harris. Attendance 24.

Virginia Military Institute.—September 29, 1920. Paper: "The Steam Engine." Speaker Mr. Land. Attendance 22.

October 30, 1920. Subject: "Mobile Ordnance Repair Truck." Speaker: Lieut. Doggett, U. S. A. Attendance 23.

University of Washington.—October 5, 1920. Dr. C. E. Magnusson spoke on "The Benefits to the Student of Joining the Local Branch of the A. I. E. E." One reel of film on the Butte, Anaconda & Pacific Railroad and two reels on the Panama Canal were shown by courtesy of the General Electric Company. Attendance 61.

West Virginia University.—October 20, 1920. Mechanical Hall. Papers read: "Electric Welding," by F. Donally; "Armature Reactions in Alternators," by C. M. Harmon; "Flood Lighting," by P. D. Brown; "Generators for 3000-volt D-C. Railway," by R. B. Walker. Attendance 13.

University of Wisconsin.—October 20, 1920. Engineering Building. Business meeting. Attendance 57.

November 3, 1920. Engineering Building. Subject: "Power Plant Surveying." Speaker: Mr. A. Taranger (student). Attendance 30.

Yale University.—October 26, 1920. Subjects: "The Electric Railway Convention," by H. V. Bozell; "Utility Problems in Connecticut," by A. E. Knowlton; "Technical Teachers at the Westinghouse Works," by W. B. Hall; "Recent Developments in Radio," by H. M. Turner, "Recent Acquisitions to the Laboratory of Industrial Control Apparatus," by L. W. Morrow; "Recent European Trip," by Professor C. F. Scott. Attendance 53.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

MEN AVAILABLE

ARMY OFFICER (Major) having fifteen years' experience prior to the war in telephone engineering, cable installations, including factory tests and d-c. light and power systems, desires position with manufacturer or firm. Experienced as administrator, executive and office manager. References if desired. E-2409.

ENGINEERING SALES, connection desired with progressive organization, preferably on Atlantic coast. Successful experience sales, construction, design, electric furnaces, power plants, public utilities. Technical graduate, good personality, energetic, resourceful and dependable, executive and publicity experience. Wide-awake, progressive man seeks new connection with broader possibilities. E-2410.

ELECTRICAL ENGINEER, college graduate, age 42, 14 years' experience, in the design and installation of generating and substations with biggest utility companies in New York and Ohio. Special experience in all kinds of substations, d-c. and a-c., indoor and outdoor up to 130,000 volts. Available November 1st. E-2411.

SALES ENGINEER, Technical graduate, age 24. At present connected with concern manufacturing elevator equipments, desires new connection where results are used as a basis for advancement. Has had G. E. Test and general engineering experience. Position desired vicinity of New York City. E-2412.

ELECTRICAL ENGINEER, or Central Station Executive. Cornell graduate, eighteen years experience, manufacturing, construction, operation. Have been general superintendent of two large hydroelectric systems in the East. Available now because of service in the Army and temporary engagement since. E-2413.

GRADUATE of technical school, age 23. Three years college training, wants electrical work anywhere; preferably installation. At present with electrical manufacturing concern. Can give good reason for leaving, also reference. E-2414.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, Armour Institute '17. Four years experience, efficiency and production engineering, engineering investigations, leading to the introduction of new and improved manufacturing

methods with two leading concerns. Permanent positions in Chicago or immediate vicinity affording an expanding future desired. Salary $3,000. Available upon short notice. E-2415.

Electrical Engineer, age 31; married. Technical graduate of good standing, highly trained in modern practise. Exceptional experience in power plant, substation, power transmission and industrial engineering. For the past four years connected in executive capacity with the largest power plant and industrial equipment installation. Best of references from former employers furnished upon request. E-2416.

Superintendent and Construction Engineer, 10 years experience in construction and operation of hydroelectric and steam power stations, transmission lines and substations. Seeks position as Construction Engineer or Superintendent of Power Stations. At present Superintendent of steam plant in the tropics, speaks Spanish and experienced in handling construction gangs. Desires foreign service, preferably in Spanish countries or S. A. Age 33 years, married. Available 30 days notice. E-2417.

Executive Engineer with broad engineering, executive and modern business training, desires connection with industrial or public utility corporation or banking concern. Experience includes industrial and public utility engineering, appraisals, financial examinations and reports; studies of organization and management. Electric railways, design, construction and operation, and power transmission. Age 42. Degree E. E. E-2418.

Electrical Engineer. Age 26. Graduate Syracuse University 1917. Electrical testing experience. Familiar with electrical equipment of steel mills, modern central station operation, main drives, (reversing type) and all branches of industrial engineering. E-2419.

Technical Graduate, I. C. S; Associate, age 29; married, foreign born. Eight years experience in maintenance, including two years G. E. test of E. R. equipment and 18 months substation and switchboard operating. Desire position leading to permanency, with industrial or operating company. Interested in electrical calculation, no office experience, willing to undergo training if position require. A-1 reference, ambitious. Salary $140.00, available January 1st. Willing to go anywhere. E-2420.

Public Utility Manager. Construction engineer and operating manager on electric power properties for past twelve years. Accustomed to large responsibility and qualified in all phases of public utility management; operating, financing, accounting, publicity, reports, appraisals, design and construction. At present engaged in the South, operating or appraisal work with large concern desired. E-2421.

Electrical Engineer, desires responsible position with central station. Experienced on large systems, power stations, substations, transmission, a-c. distribution and d-c. distribution. Can supervise the making of plans, and handle construction and operating forces. Technical graduate, age 34; married. Associate member American Institute of Electrical Engineers. E-2422.

Research Engineer, with experience in developing various electrical projects, including radio, has had executive charge of extensive and important engineering work as Professor of Physics and electrical engineer, has carried on researches in three noted University Laboratories; now desires connection with large corporation planning the organization of its research department. E-2423.

Executive Engineer, capable of taking charge of development of electrical and mechanical apparatus or position as factory manager or superintendent; 35 years old. Thirteen years' experience. E-2424.

Electrical Engineer. Twelve years with electrical manufacturing companies as assistant electrical engineer. Twelve years in responsible charge of industrial electrical work for large engineering corporation. Desires responsible position with or partnership in engineering firm; executive position with large industrial organization; or to obtain capital for establishing independent engineering company. E-2425.

Sales Engineer, wish esto obtain manufacturers' agency, for direct representation of electrical and mechanical apparatus, equipment and accessories for N. Y. C. and eastern territory. E-2426.

Turbine Engineer, with nine years experience in the estimating, design and testing of steam turbines, centrifugal compressors, etc. Is thoroughly familiar with mathematical principles involved and with the latest turbine practise both stationary and marine. Would like position as chief or assistant turbine engineer, preferably with small growing concern. Location New England preferred. E-2427.

Electrical Engineer, 8 years' experience power house, substation construction and general wiring. Some teaching experience. Two years detailed as inspector of electrical material and machinery for Bureau of Steam Engineering U. S. N. Age 27; married. Available January 1st. Salary desired $2200. E-2428.

Graduate Mechanical and Electrical Engineer (1910). Ten years experience with the largest engineering corporation in advanced problems on electric power generation and distribution, as designer. "Trouble man" and research engineer. Salary $3000. Location preferred New York vicinity. E-2429.

Electrical Engineer. Associate A. I. E. E. Age 34, single. Spanish. One year G. E. test, experience in railroad work, irrigation developments, and installation of small lighting plants in South America, wants position in company operating lighting or power plant, or with manufacturing exporter. E-2430.

Electrical Engineer, age 29; married. Technical graduate. Test and railway engineer Dept. General Electric Company; Electric Engineer Railway supply house. At present engaged in organization work. Has executive ability and can handle men. Desires position as assistant superintendent in industrial concern or sales engineer. E-2431.

Engineering Executive, sales engineer, or sales representative; electrical engineer, technical graduate; married. At present connected. Experience includes electrical machine design, central station transmission, distribution, design, operation and sales engineering. East preferred. E-2432.

Electrical Engineer. Five years responsible experience; including cost, estimating, purchasing, and field work, with engineering construction firm. Two years in charge of experimental and development work and one year as manufacturing manager with large company. Experienced in factory accounting and organization. Present salary $5,000. E-2433.

Investigation Engineer. Executive consultee, adviser, and correspondent; investigations and researches in shop, laboratory, or office. Mathematical analysis, recommendations and reports; to improve tools and materials, methods, processes and equipment; for betterment of output, capacity, economy, and efficiency; in production, operation, and maintenance; estimates, specifications and costs. Stevens M. E. and Ex-Naval Engineer. E-2434.

Graduate Electrical Engineer (1916). Age 25. Four and a half years general engineering and industrial experience. At present production manager of large plant of 50,000-unit monthly capacity. Prefer to connect with growing industrial concern in Middle West as Production Manager or Assistant Works Manager. E-2435.

Electrical Engineer. Technical graduate. Two years varied test experience with large electrical manufacturer; two years design of direct-current railway motors. Age 29; not married. Position wanted with interurban operating on high-voltage direct current or with railroad contemplating electrification. Minimum salary to start $3000. Available on 30 days notice. E-2436.

Graduate Electrical Engineer, B. S. E. E. Married; age 32. Desires location in Middle West. Experienced in d-c. and a-c. installations, operation and trouble shooting, automotive electrical equipment and storage batteries, battery charging equipment, conduit work, office records and handling of men. In present location five years. E-2437.

Cornell Graduate, 1920 M. E. Desires position with a manufacturing company east of the Mississippi River in Production of Cost Department. Ten weeks experience with large manufacturing company in Production Control Department which has now been discontinued because of general curtailment. Member A. I. E. E. E-2438.

Electrical and Mechanical Engineer. Age 32. University education, business experience. Steel Plant, R. R. Metal and Rubber Goods Mfg. Several years Inspector charge tests and construction, Designer, Chief Draftsman, good organizer. Desires job as Assistant Manager, Asst. Chief Engineer, Chief Draftsman or similar. Location immaterial. E-2439.

Electrical Engineer, 26, five years manufacturing, public utility, and operating experience, desires position of responsibility with progressive concern in middle west. Technical graduate; married; chief engineer of destroyer during war. At present assistant electrical engineer with manufacturing company but desires change to strictly electrical line. Salary $225. E-2440.

HEAD OR ASSOCIATE PROFESSORSHIP in Electrical Engineering, wanted by A. I. E. E. Member. Age 33. Three years of commercial work and 8 years of teaching in large universities. Prefers work in a rapidly growing school where hard work and results count. Best references. E-2441.

ELECTRICAL ENGINEER, graduate in Mechanical and Electrical Engineering. Age 40. British subject, married; Member A. I. E. E.; G. E. Test. Twelve years experience in the installation of large water-driven units and electrical apparatus up to 110,000 volts. Recently resident engineer on large hydroelectric development in Europe. Some knowledge of Spanish. Will go anywhere. South America preferred. E-2442.

OPPORTUNITIES

ENGINEERING PERIODICAL of highest standing has opportunity for technically educated man with editorial experience, initiative and judgment, for position of responsibility. Replies should embody the essential facts. Z-2497.

YOUNG MAN with technical training. Experience in Railway distribution desired. Location Md. Z-2496.

ELECTRICAL OR MECHANICAL UNIVERSITY GRADUATES wanted for sales work with a well established electrical manufacturer in the middle west. Correspondence confidential. Give all particulars. Location Mo. Z-2456.

MECHANICAL ENGINEER for Power Stations Department, Testing Division, to have actual charge of one of new Power Plants in Pittsburgh. Z-2458.

MECHANICAL ENGINEERS, who have had several years experience in gas distribution, efficiency, compressing station operation and high pressure transportation. Four men needed. Location Penna. Z-2459. (Men to ultimately work into executive positions.)

ELECTRICAL ENGINEERS, one for Distribution Department, having experience in design, operation and construction in the field and office—the second a man who is capable of doing general engineering work in the way of design of power stations, equipment, efficiency, etc. Location Penna. Z-2460.

ENGINEER, Electrical or Mechanical, wanted by large Electrical Manufacturer, to specialize as Classification Expert. Will be expected to extend an existing classification similar to Dewey, to keep it up-to-date as the industry progresses and to develop other classification systems as needed. State full particulars, giving age, education, experience, and salary expected. Location New York. Z-2416.

STATISTICIAN, preferably an Electrical Engineer wanted by a prominent Electrical Manufacturer for collecting and compiling data on all phases of the electrical industry. Give full particulars, age, education, experience and salary expected. Location New York. Z-2417.

PRACTICAL ELECTRICAL ENGINEER along experimental lines. One who has had experience, or working knowledge of the application of electricity to household devices. Location Ohio. Z-2401.

YOUNG PROGRESSIVE ENGINEER with some experience in design of air- and oil-brake types of circuit breakers. Location Penn. Z-2407.

PHYSICIST experienced in light and sound to be in charge of laboratory for large industrial company in Connecticut. Application by letter only. Location Bridgeport, Conn. Z-2398.

YOUNG MAN TECHNICALLY TRAINED. Some practical experience for position in electric operating department of a large electric light and power company located in an Atlantic Seaboard city. Give age, experience, references and minimum salary expected at start. Z-2382.

PRACTICAL ELECTRICIAN for repairing, assembling, testing, etc. of motors, controllers and other electrical apparatus. Man about 28 years old desired. Only men who wish to work up to superintendent and stay in this line of work desired. Hours 7:45-5, noon Saturday. Location New York City. Z-2365.

CHIEF INSPECTOR for plant in middle west manufacturing electrical machinery. Work to cover both mechanical parts inspection, and electrical inspection of subassemblies. Technical man desired—thirty to forty years old who has had broad experience in manufacturing work; must be good executive and be able to coordinate his work with that of other departments without friction. Location, Ohio. Z-2370.

CHEMIST familiar with loss temperature distillation of coal treatment of by-products received from distillation, also briquetting and burning of pulverized coal. Location New York City. Z-2349.

INSTRUCTOR in Physics. Location Missouri. Z-2350.

ELECTRICAL DESIGN ENGINEERS for substation work. Must be good executives as they will have entire charge of this work. Application by letter only. Experienced men will be considered. Location New York City. Z-2353.

MECHANICAL ENGINEER; two or three years experience in power plant operation. Must be capable of working with chief engineer, of showing him how to get better results from the boiler and engine room. Installation consists of approximately 2200 boiler horse power and a total electric load of 5500 kw-hr. In addition we have numerous problems of power distribution which require the investigation of a technical man. Location New York City. Z-2357.

PRACTICAL RUBBER WIRE AND CABLE MAN, capable of laying out and organizing production of modern plant in foreign country. Give full details regarding experience, age, references, etc. in first letter. Location France. Z-2358.

SUPERINTENDENT for company manufacturing storage batteries. Must have had storage battery experience. Application by letter giving details. Location New York City. Z-2339.

PHYSICIST, Ph. D. or equal, desired by large and growing electrical research organization for field investigations, supervision of laboratory experiments, etc., necessary in connection with the development of apparatus. Young man preferred. State age, technical training, experience and salary expected. Location New York City. Z-2340.

INSPECTOR for electrical materials, especially cables. Technical graduate. Experience desirable but not essential. Salary will depend upon the experience. Young man of limited technical training if of good mental capacity will be considered. *Application by letter only.* Location New York City. Z-2341.

ELECTRICAL AND MECHANICAL ENGINEER familiar with sea-going hopper type suction dredges and hydraulic auction pipe line dredges, also with steam and gasoline tugs and launches. Will be expected to assist the Superintendent of dredges in the operation and repair of a fleet of 6 dredges with attendant plant. Applicant should give educational qualifications, employment history, age and all other pertinent information. Will be expected to undergo civil service examination for appointment to grade of Junior Engineer or Superintendent. Location Texas. Z-2323.

ELECTRICAL ENGINEER for testing and assembling d-c. and a-c. motors. Location Wis. Z-2326.

ENGINEER, technical engineer, French nationality with broad American mechanical and commercial experience in the design, construction, installation and operation of machinery. Position requires residence abroad and applicant must have a thorough command of French. Appointment will be made by letter only giving age, nationality, experience and salary desired. Z-2330.

MECHANICAL DESIGNER, with practical experience on electric switching apparatus. Permanent work for the right man. State age, experience, education and salary expected. Location Penn. Z-2322.

ELECTRICAL ENGINEER with technical training, experienced in design of electric and of generating stations, electric transmission and motor applications as applied to industrial work. Any power-plant operating experience will be considered an asset. Location Ohio. Z-2304.

ELECTRICAL ENGINEERING GRADUATE to act as an engineering assistant in connection with preparation of estimates and proposals for service extensions to transmission and distribution system. Applicant can be a recent graduate or one with a few years' experience. Location Penn. Z-2307.

JUNIOR ENGINEERS or recent graduates for power station testing. Practical experience unnecessary. Work consists of electrical testing, covering calibration of instruments and wattmeters; a-c. and d-c. relay calibration and other power plant tests, location New York City. Z-2244.

ASSISTANT PRINCIPAL OF ELECTRICAL ENGINEERING with practical knowledge of telegraphy and telephony, also knowledge of wireless desirable. Must be able to answer technical letters, editing, etc. along these lines. Permanent position. Location Scranton, Pa. Z-2192.

FACTORY MANAGER. Polyphase Motor Manufacture. Expansion of facilities and rearrangement of duties have left open position of Factory Manager. Satisfactory record of results accomplished must be submitted, including production, and indicating a thorough familiarity with economical design and manufacture. This is an excellent opening for a man of the proper qualifications, and first communication should give complete information as to ability, salary expected, etc. Only those of proved ability will be considered. Location Michigan. Z-1620.

INDUSTRIAL PHYSICIST or Engineer interested in research or electrical control problems. Location Middle West, salary according to training and experience. Location Wisconsin. Z-1525.

INDUSTRIAL PHYSICISTS. An established research laboratory of well-known manufacturer offers positions to qualified scientific men who have research ability. One or two men of scientific training in physics and experience in research are desired. There is also position open for a physicist with less experience but with creative ability. Working conditions are attractive and positions are permanent. Location Ohio. Z-558.

UNITED STATES CIVIL SERVICE EXAMINATION

SENIOR ENGINEER, Grade 2. C.E. E.E. M.E. Signal, Structural, Telephone and senior Architect. Salary—$2500 and bonus.

ELECTRICAL DRAFTSMAN. War Dept. Application received until March 7, 1921. Salary depends on experience.

SUPERINTENDENT OF ELECTROPLATING. Salary—$3000-4500. Application to close Dec. 7, 1920.

SUPERINTENDENT OF CONSTRUCTION. Application to close Dec. 7, 1920. Salary—$2500-3000.

MAN FOR BOILER AND POWER HOUSE ASSISTANT in foreign country. Applicant must be single, not over thirty-five years of age, healthy and familiar with Edgemoor type of boiler. In applying, state particulars of experience, give references and salary desired. Location India. Z-2464.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Leo Arany, Room 201 Parkway Bldg., Broad & Cherry Sts., Philadelphia, Pa.
2.—James F. Elliott, Electric Controller & Mfg. Co., Oliver Bldg., Pittsburgh, Pa.
3.—O. H. Horner, c/o Black & Veatch, 507 Interstate Bldg., Kansas City, Mo.
4.—Wilfred Langille, Marion Station, Public Service Electric Co., Jersey City, N. J.
5.—H. S. Logan, 215 15th Street, Seattle, Wash.
6.—Leonard Morey, 1067 East 153rd Street, Cleveland, Ohio.
7.—P. J. Reese, 7th & Main Street, Royal Oak, Mich.
8.—Richard G. Thompson, Alliance Power Co., Edmonton, Alberta, Can.
9.—J. Andre Wells, Western Electric Co., 463 West Street, New York, N. Y.

MEMBERSHIP—Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED NOVEMBER 12, 1920

*ALLIS, SELDEN P., Salesman, General Electric Co., Chicago, Ill.

ARIMURA, SHINNOSUKE, Electrical Engineer, Nihon Suiroku Kabushiki Kaisha, Marunouchi Kojimachuku, Tokyo, Japan.

ARMISTEAD, FREDERICK V., Designing Engineer, General Electric Company; res., 216 Glenwood Blvd., Schenectady, N. Y.

BABCOCK, COURTLANDT W., Control Engineer, Wesinghouse Elec. & Mfg. Co., 10 High St., Boston, Mass.

BAKER, HARRY G., Supt., Clark Electric Power Company, Tooele, Utah.

BANNISTER, ALBERT Engineer-in-charge, Switchgear Tender Dept., Metropolitan-Vickers Electrical Co., Ltd., Trafford Park, Manchester, Eng.

BASU, SUSTHIR K., Electrician, The Tata Iron & Steel Co. Ltd., 106 Northern Town, Jamshedpur, India.

BELL, HUGH G., Research Engineer, Metropolitan Vickers Electrical Co., Manchester, Eng.; 514 McNair Ave., Wilkinsburg, Pa.

BLACKWOOD, ARCHIBALD G., Power House Supt., Public Works Dept., Lake Coleridge, N. Z.

BLODGETT, DAN. A., Chief Electrician, Night force, Chevrolet Motor Co., 615 W. 2nd St., Flint, Mich.

BOONE, FRANK P., Electrical Engineer, U. S. Food Products Corp., 309 Jefferson Bldg., Peoria, Ill.

BOYD, WILFRED R., Engineer, Welding Dept., Burke Electric Co., Erie, Pa.

BRADLEY, HERBERT E., Designer, New York Central Railroad, Grand Central Terminal, New York; res., 380 Hawthorne Ave., Yonkers, N. Y.

BRETTLE, ARTHUR C., Electrical Engineer, General Electric Co., Electric Bldg., Buffalo, N. Y.

BREWER, AUBREY, Shift Foreman, Cheoah Development, Tallassee Power Co., Tapoco, N. C.

BUELL, HARRY C., Industrial Engineer, Consumers Power Co.; res., 1711 Court St., Saginaw, Mich.

CHAMBERLAIN, ROBERT F., Asst. Professor of Electrical Engineering, Cornell University; res., 4 South Ave., Ithaca, N. Y.

CLARKE, ARNIM R., Service Manager, Engineering Services Ltd., 28 Dundas St. West, Toronto, Ont.

COLLINS, CHARLES E., Vice-President & General Manager, The L. E. Myers Co., 1117 Monadnock Bldg., Chicago, Ill.

CONAWAY, RALPH ARNOLD, Draftsman, Georgia Railway & Power Co., 456 Electric & Gas Bldg., Atlanta, Ga.

CREAMER, WALTER J., JR., Teacher, University of Maine, Orono, Maine.

CROSS, GORDON F., Construction Engineer, Hydro-Electric Power Commission, 190 University Ave., Toronto, Ont.

DA FONSECA TELLES, FRANCISCO E., Professor of Electrical Engineering, Escola Polytechnica, S. Paulo, Brazil, S. A.

DE MOTT, GEORGE L., 3rd Asst. Examiner, U. S. Patent Office, Washington, D. C.; res., Arlington, Va.

DICKIE, JOHN A., Electrical Engineer, Kellogg Switchboard & Supply Co., Chicago; res., Hotel Washburn, Waukegan, Ill.

*DRESSLER, ALFRED F., Instructor, New York Electrical School, 39 W. 17th St., New York, N. Y.

ELLIOTT, LEE M., Asst. to Electrical Engineer, Compania Cubana, Tatibonico, Prov. Camaguey, Cuba.

FEELY, JOHN J., General Supt., Thompson Bonney Co., 146 Pearl St., Brooklyn, N. Y.

FIELDER, EBENEZER, Substation Engineer, Public Works Dept., Addington Substation, Lake Coleridge Electrical Supply, Christchurch, N. Z.

FITZSIMONS, THOMAS S., 19 Tapscott St., Kimberley, S. Africa.

FLEMING, ELLIOTT, Electrical Engineer, Union Steamship Co., Port Chalmers, N.Z.

FRIGON, AUGUSTIN, Commissariat General de Canada, 17 Boulevard des Capucines, Paris, France.

FRIZZELL, LIONEL K., Chief Electrician, Dominion Coal Co. Ltd., Glace Bay, N. S.

FUJISAWA, KIUSABURO, Electrical Engineer, Tokio Electric Light Co., Tokio Dento Kaisha, Marunouchi, Tokio, Japan.

GARTNER, C. K., Representative, The Sperry Gyroscope Co., 40 Flatbush Ave.; res., 2511 Madison St., Brooklyn, N. Y.

GIBBONS, WALTER J., Instructor in Electrical Engineering, Defense Dept., New Zealand Government, Rotorua, N. Z.

GRAHAM, HERBERT L., Wire Chief, B. & O. R. R. Co., Jenkins, Ky.

GRIFFITH, LAFAYETTE F., Supt., Light & Power Dept., Little Rock Railway & Electric Co., Little Rock, Ark.

HASTINGS, JOHN LE ROY, Junior Student Apprentice, Motor Eng. Dept., Westinghouse E. & M. Co., E. Pittsburgh, Pa.; res., 702 So. 3rd Ave., Bozeman, Mont.

HAYNE, JOHN, Supt., Hydro Power Commission of Hanover, Hanover, Ont.

HIROTA, MITSUYOSHI, Electrical Engineer, Electric Works, Mitsubishi Zosen Kaisha, Kobe, Japan.

HOCH, ELLERY T., Engineer, Western Electric Co., Inc., 463 West St., New York, N. Y.

HOISINGTON, GEORGE P., Cable Splicer, Commissioners of Lincoln Park, Clark & Center Sts.; res., 551 Aldine Ave., Chicago, Ill.

HOLDERNESS, H. C., Transformer Engineering Dept., General Electric Company, Pittsfield, Mass.

HUANG, TUH SIU, Engineering Dept., New York Edison Co.; res., 607 W. 139th St., New York, N. Y.

HUDSON, E. L., Asst. Chief Engineer, Central Illinois Public Service Co., Harrisburg, Ill.

INOMATA, TADASU, Engineer, Electric Dept., Kawasaki Dockyard Co., Kobe, Japan.
ISAKA, KATSUZO, Chief Engineer, Nagoya Electric Light Co., Shinyanagimachi, Nagoya, Japan.
ISHIGURO, KUICHI, Electrical Designing Engineer, Mitsubishi Shipbuilding Co., Nagasaki, Japan.
ISHIKAWA, RAIJI, Engineer, Shibaura Engineering Works, 1 Kanasugi, Shibaku, Tokio, Japan.
JACKSON, JOHN B., Engineering Dept., Commonwealth Edison Co.; res., 4168 Cullom Ave., Chicago, Ill.
JONES, ORA O., Motor Inspector, Commonwealth Edison Co., 72 W. Adams St.; res., 1941 Congress St., Chicago, Ill.
JONSON, MARCUS E., Electrical Engineer, Andersen Meyer Co. Ltd., Shanghai, China.
KAMBARA, JO., Chief Electrical Engineer, Japan Nytrogen Fertilizer Mfg. Co., Minamata-mati, Asikita-gun, Kumamoto-ken, Japan.
KEISER, MORRIS, Asst. Electrical Engineer, Acoustics Section, Bureau of Standards, Washington, D. C.
KNIERIM, GUSTAVE J., Construction Foreman, Johnston Livingston & Company, Inc., Astoria, L. I., N. Y.
LAUTHERS, JAMES PEARL, Master Sargent, C. A. C. (Master Electrician), U. S. Army, Fort Andrews, Mass.
LEAHY, JOSEPH A., Polar Wave Ice & Fuel Co., Grand & Olive Sts., St. Louis, Mo.
LEVY, REGINALD M., Engineering Asst., Victorian Electricity Commissioners; res., 27 Robe St., St. Kilda, Melbourne, Aus.
MARSHALL, FRANK O., Asst. Chief Electrician, The Pullman Co., 701 Pullman Bldg., Chicago, Ill.
MIYAKAWA, RIICHI, Manager, Drafting Section, Shibaura Engineering Works, 1 Kanasugi, Shibaku, Tokio, Japan.
MOCK, FRANK CHARLES, Engineer, International General Electric Company; res., 211 Seward Place, Schenectady, N. Y.
MODRAK, PETER, Designing Draughtsman, Department of Mines, Treasury Bldgs., Brisbane, Queensland, Aus.
MONGAN, HUGH B., General Foreman & Engineer, Central Garage and Electric Supply Co., Hagerstown, Md.
MOORE, GEORGE M., Supt., Lamar Light & Power Plant, Lamar, Colo.
MOULTON-REDWOOD, WILLIAM J., Asst. Works Engineer, Canadian National Carbon Co., Ltd., Hillcrest Park, Toronto, Ont.
MURAYAMA, SHIKANOSUKE, Chief Engineer of Metallurgical Dept., Mitsui Mining Co., Ohmutashi, Fukuokaken, Japan.
MURDOCH, KENNETH B., Electric Steel Student, Crucible Steel Co. of America—Atha Works, Harrison; res., 24 Walnut St., Newark, N. J.
NISHI, TAKESHI, Asst. Professor, Elec. Engg. Dept., Tokyo Imperial University, Tokyo, Japan; 50 Church St., New York, N. Y.
ODAJIMA, SHUZO, Electrical Engineer, Toba Ship Yard; Suzuki & Co., 220 Broadway, New York, N. Y.
O'REGAN, STEPHEN P., Marine Engineer; res., 57 Harrison Ave., Port Richmond, N. Y.
PARKER, PERCY C., Distribution Engineer, Newcastle Elect. Supply Co., Carville Power Sta., Wallsend-on-Tyne; res., Newcastle-on-Tyne, Eng.
PARRA, ALBERT R., Maracaibo Electric Light Co., Maracaibo, Venezuela, S. A.
*PATTERSON, G. R., Electrical Engineer, Pittsburgh Transformer Company, Pittsburgh; res., 39 S. Howard Ave., Bellevue, Pa.
PEMBLETON, FRED W., Asst. Foreman, General Electric Co.; res., 1742 Illinois St., Ft. Wayne, Ind.
PHILLIP, HARRY J., Chief Electrician, American Cyanamid Co., Brewster, Fla.
PLATT, ALBERT H., Chief Electrician, Bullard Machine Tool Company; res., 108 Stillman St., Bridgeport, Conn.
PODESTA, ARTHUR, Head of Electrical Dept., Scriven Brothers, (Chile) Ltd., Casilla 1597, Santiago, Chile, S. A.
PRADHAN, SHRIKRISHNA R., Student Engineer, General Electric Company, West Lynn, Mass.
REYES, SALUSTIANO, Electrical Engineer, Philippine Government, Bureau of Insular Affairs, Washington, D. C.
ROBERTS, GEORGE W., Electrical Engineer, General Electric Co., Lynn, Mass.
ROMANO, MICHAEL, U. S. Navy Inspector, General Electric Co., Schenectady, N. Y.
ROSELLE, HENRY, Foreman Electrician, Iowa Railway & Light Co., Cedar Rapids, Iowa.
RUDOLPH, LOTHAR ERNST, Automatic Tel. Inspector, New Telephone Bldg., Omaha, Nebr.
*SCHAEFER, FREDERICK LEROY, Chief Engineer, Cupey Sugar Co., Cayo Mambi, Oriente, Cuba.
SCHELL, LEROY S., JR., Electrical Engineer, General Electric Company, Pittsfield, Mass.
SEAMAN, WM. E., Electrical Draftsman, Eng. Dept., New York Edison Co., 130 E. 15th St.; res., 495 E. 188th St., New York, N. Y.

SISLER, C. O., Asst. Supt., Lake Superior Paper Co.; res., 20 The Drive, Sault Ste. Marie, Ont., Can.
SMITH, FLOYD T., Engineer, General Electric Co.; res., 145 Elmer Ave., Schenectady, N. Y.
SMITH, MERRILL J., Electrical Engineer, with Jackson & Moreland; res., 77 Westland Ave., Boston, Mass.
STITES, SAMUEL, Salesman, General Electric Co., Nashville, Tenn.
TAYLOR, H. L., Asst. Inspector of Electrical Engineering, Provincial Government, Court House, Vancouver, B. C.
TREADWELL, LEON H., Proprietor, Treadwell Electric Co., 681 Main St., Worcester, Mass.
TYNE, GERALD F. J., Student, Rensselaer Polytechnic Institute, 2160 13th St., Troy, N. Y.
UMSTEAD, ARNER O., Supt., Electric Transmission Co. of Virginia, Big Stone Gap, Va.
UYESAKA, IWAO, Electrical Engineer, Kyushu Hydro-Electric Co., Oita, Kyushu, Japan.
VAN NESS, NEIL T., Instructor, Bliss Electrical School, Takoma Park, D. C.
VOSS, HENRY LINCOLN, Electrical Engineer, Shourds-McCormick Co., 510 Tribune Bldg., Terre Haute, Ind.
WAI, ON, Electrical Engineer, T. E. M. A., North Soochow Road, Shanghai, China.
WELCH, LEO T., Chief Engineer, Alpha Electric Construction Co., 124 Hudson Ave., Albany, N. Y.
WESTERVELT, H. M., Engineer, Ind. Control Dept., Sprague Elec. Co., Bloomfield; res., 25 Ivanhoe Terrace, E. Orange, N. J.
WHITEMAN, W. S., Insulator Specialist, Westinghouse Elec. & Mfg. Co., 1333 Candler Bldg., Atlanta, Ga.
WOOD, HOMER E., Construction Foreman, Miller Engineering Co., Seattle; res., 2514 N. Union Ave., Tacoma, Wash.
WRIGHT, MITCHELL C., Treasurer, K. W. Electric Company, 49 Lawrence St., Newark, N. J.
YAMAGUCHI, SUESABRO, Designing Engineer of Electrical Machinery, Mitsubishi Zosen Kaisha, Nagasaki, Japan.
YOUNG, WILLIS M., Lieut., U. S. Navy; res., Wenona, Ill.
Total 107,
*Former enrolled Students.

ASSOCIATES REELECTED NOVEMBER 12, 1920

DOUGLAS, JOHN F. H., Asst. Prof. Electrical Engineering, Marquette University, Milwaukee, Wis.
DRAKE, CHESTER W., General Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., Irwin, Pa.
LUTHER, GEO. D., Manager, Seattle Branch, The Electric Storage Battery Company, 811 White Bldg., Seattle, Wash.
TAYLOR, EDWARD, Designing Engineer, Automatic Railway & Industrial Substations, General Electric Co., 923 Monadnock Bldg., Chicago, Ill.

MEMBERS ELECTED NOVEMBER 12, 1920

ALBRECHT, E. JULIUS, Engineer, Hydro-Elec. Dept., James O. Heyworth, 505 Harvester Bldg., Chicago, Ill.
BUTLER, W. H., Electrical Contractor, 163 West Seymour St., Philadelphia, Pa.
BYNG, EDWARD S., Supt., Cable & Line Consruction Dept., Western Electric Co., Ltd., N. Woolwich, London, E. 16, Eng.
DOUGHERTY, HENRY M., Construction Engineer, Chile Exploration Co., Chuquicamata, Chile, S. A.
DU RIEU, EDGAR F., Engineer for Electric Construction, Hydro-ElectricDept., Hobart, Tasmania.
HOBART, KARL E., Operating Engineer, Sanitary District of Chicago, Chicago; res., 456 Drexel Ave., Glencoe, Ill.
SCHIFF, MARTIN, Asst. Engineer, Roth Bros. & Co., Inc., 1400 W. Adams Street, Chicago, Ill.
SMITH, ROBERT W., Chief Electrical Engineer, De Beers Consolidated Mines, Ltd., Consulting Elec. Engineer, City Council, Kimberley, S. Africa.
VIALL, ETHAN, Editor, *American Machinist*, McGraw Hill Co., 36th St. & 10th Ave., New York, N. Y.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held October 25, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary

To Grade of Fellow

HAMILTON, JAMES L., Chief Engineer, Century Electric Co., St. Louis, Mo.
HIBBARD, HARRY L., Manager, Marine Dept., Cutler-Hammer Mfg. Co., New York, N. Y.
LILJENROTH, FRANS G., Consulting Engineer, E. I. du Pont de Nemours & Co., Wilmington, Del.

To Grade of Member

ANDRUS, RAYMOND J., Operating Engineer, Central Power Co., Grand Island, Neb.
BOLSER, M. O., Technical Asst., Distribution Dept., Bureau of Power & Light, Los Angeles, Cal.
DOWNTON, PERCIVAL G., Branch Manager, Electric Storage Battery Co., Minneapolis, Minn.
DRAKE, CHESTER W., General Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
FIRESTONE, SIEGMUND, Consulting Engineer, Rochester, N. Y.
GENT, RUFUS T., Plant Engineer, Hydro-Electric Power Commission, Niagara Falls, Ont.
LOCKYER, R. H. N., Engineer in Charge, West Kootenay Power & Light Co., Trail, B. C.
MILLAN, WALTER H., Supt. of Substations, Union Electric Light & Power Co., St. Louis, Mo.
NELSON, NORMAN C., Electrical Engineer, North Pacific Public Service Co., Bremerton, Wash.
NOTOMI, IWAICHI, Director, Shibaura Engineering Works, Tokyo, Japan.
POTTER, CHARLES P., Engineer in Charge, Large Motor and Transformer Engineering Depts., Wagner Electric Mfg. Co., St. Louis, Mo.
ROBERTSON, ARTHUR S., Erection Engineer, Hydro-Electric Power Commission, Niagara Falls, Ont.
ROSWELL, CHARLES M., Engineer, Charleston Consolidated Railway & Light Co., Charleston, S. C.
SIMONSON, GEORGE M., Chief Electrical Engineer, State of California Department of Engineering, Sacramento, Cal.
TAYLOR, EDWARD, Designing Engineer, General Electric Co., Chicago, Ill.
VOLKMANN, WILLIAM, Jr., Assistant to Chief Engineer, Toronto Power Co., Toronto & Niagara Power Co., Toronto Railway Co., Toronto, Ont.
WARNER, WILLIAM H., Distribution Engineer, New York & Queens Electric Light & Power Co., Long Island City, N. Y.
YAMBERT, D. W., Electrical Engineer, France Stone Co., Toledo, O.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before December 31, 1920.

Aabye, Jorgen, New York, N. Y.
Abbett, Hugh W., Indianapolis, Ind.
Adams, Frederic, O., Toronto, Ont.
Anderson, Arthur H., Watervliet, N. Y.
Andrews, Alvin G., Detroit, Mich.
Armstrong, H. V., Toronto, Ont.
Armstrong, Morris S., Philadelphia, Pa.
Bagnall, George E., Detroit, Mich.
Balhatchet, Harold S., Toronto, Ont.

Buss Fuses

of Renewable Type are installed throughout the Durant Building to protect its electrical wiring and equipment.

They were bought on merit alone. As the Engineer expressed it "They are the only fuses good enough to be put in this wonderful building."

Buss Fuses are one of only four makes of fuses approved by Underwriters' Laboratories, Incorporated, in all sizes and voltages.

You cannot afford to buy a fuse not so approved. Real merit can hardly exist in part of a manufacturer's output, and not in the whole.

The Durant Building, Detroit, Mich. (Albert Kahn, Architect) is the largest office building of its kind in the world. It contains a rentable area of 1,054,685 square feet, and approximately four miles of corridors.

Buss superiority is interestingly explained in our F. C. book. Write for it.

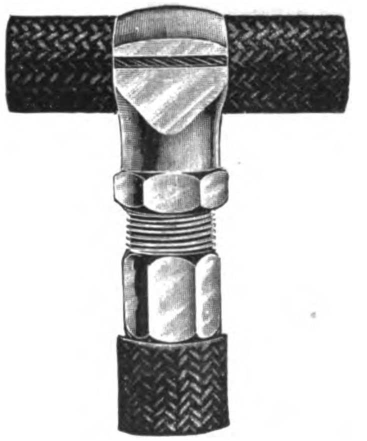
Bus Connections Are Best Made With Dossert Cable Taps—



Dossert Cable Tap

The Dossert tapered sleeve principle of securing 100% conductivity has superseded solder methods in switchboard connections, cable taps, wire and cable connections and branches. In your own installations you can profitably employ this established standard principle of solderless connections—their simplicity, ease of installation or change, and the saving they accomplish is apparent.

The installation shown above is taken from a large power station in Seattle, Wash. Dossert cable taps are used in making the connections from solid buses to current transformers.

The Dossert catalog will point out for you many money saving services. ***Send for it today.***

Dossert & Company

242 West 41st Street, New York

DOSSERT

SOLDERLESS-Connectors and Terminals

Aluminum Conductors

—Steel Reinforced

Aluminum cable with core of steel realizes on the lightness and conductivity of the aluminum and the extra high strength of the steel.

A new edition of our **Electrical Conductor Handbook** was published last month. If your name is not already on our mailing list, fill out and mail us the coupon.

Fuse hunting

—while production waits

WHENEVER a fuse blows, production is stopped.

Then, while a workman hunts up an electrician and the electrician tests for the blown fuse, the motor, the motor-driven machinery, and a little knot of workmen go on a short vacation.

Fuse hunting takes more time than most people realize. Time it yourself in your own plant. You will find that the average time required to locate and replace a blown fuse is twelve minutes.

With the Condit Type N 1 Oil Motor Starter, fuse hunting is never necessary. This switch does not protect by fuses. In the event of overload, short-circuit, undervoltage or single phase running, the ball-bearing latch is tripped automatically and the contacts are opened under oil.

A Condit representative (located near you) will be glad to call to tell you more about the advantages of a circuit breaker.

CONDIT

Condit Type N-1 Oil Motor Starter 30 Amperes 600 Volts.

CONDIT ELECTRICAL MANUFACTURING CO.

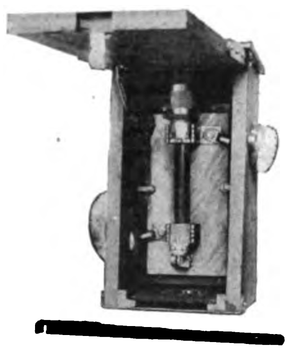
Manufacturers of Electrical Protective Devices

South Boston, No. 27, Mass.

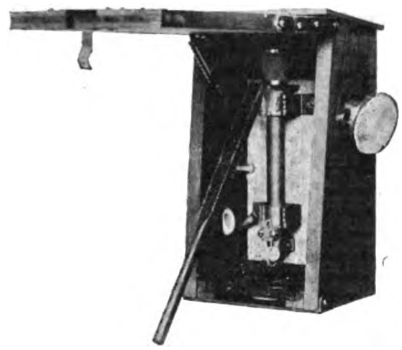
MATTHEWS SAFETY STICK
and the
NEW TYPE CG MATTHEWS FUSWITCH

A Matthews Safety Stick is packed in every other Type CG Matthews Fuswitch

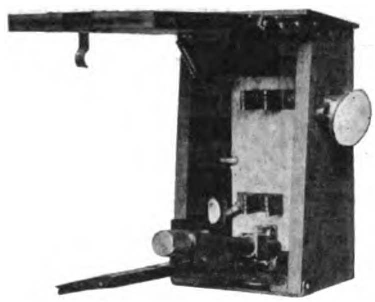
It is used first to open the door of the Type CG Matthews Fuswitch



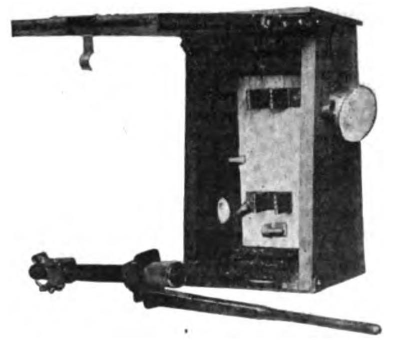
The Matthews Safety Stick makes it entirely unnecessary for a workman to touch the box



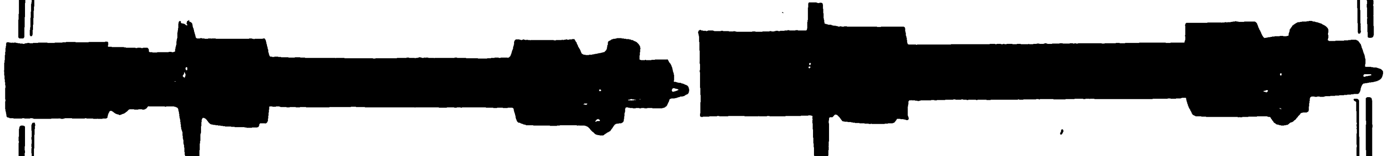
After the door is open the Matthews Safety Stick is used to pull down or disconnect the fuse cartridge of a Type CG Matthews Fuswitch



When the fuse cartridge has been pulled down to a right angle it can be easily removed by moving the Matthews Safety Stick to the right



When the cartridge is entirely removed from the Type CG Matthews Fuswitch it can then be taken off Matthews Safety Stick



"Close up" of the Fuswitch which is both a fuse and a switch. Note the large mass of metal at the explosion end. This radiates the heat and prevents the carbonization of the insulated tube

W. N. MATTHEWS, PRESIDENT AND TREASURER

MARTIN J. WOLF, VICE-PRESIDENT

MANUFACTURERS OF MATTHEWS PATENTED SPECIALTIES

ST. LOUIS, U. S. A.

Aside from 100 other uses there are thousands of places where *C-H Electric Space Heaters* may be used—some proven uses are indicated

Heating Office and Charging Batteries

"We have a 500 Volt D. C. line into our place of business and several of the employes have cars which have storage batteries that need charging from time to time. Well, we got together and talked about harnessing the 500 Volt circuit. We had some C-H Space Heaters so here is what we did:—By using five heaters we obtained five amperes. Added five more heaters hooked in multiple which gave us a little less than ten amperes.

We found that by using the Space Heaters in this way we could kill two birds with one stone, i. e., heat the office and at the same time charge our batteries."

Electric Locomotives

"We are using C-H Space Heaters to prevent moisture from getting in the motors and electrical wiring of our electric locomotives by placing six or more heaters on a rack under the locomotives. The power is applied when the locomotives are at rest in wet places in the tunnels."

Oil Switches

"The oil switch inspector of a New England Power Co., had considerable trouble with condensation of moisture in our switches of the 110,000 volt type, until a C-H Heater was used to keep the temperature uniform."

Drying Out Transformer Cores and Motors

"An asbestos lined box made of sheet steel in which we will place about thirty Space Heaters properly connected to switches so as to be able to get different heats, and so designed that when used with a small blower all the air passing through the box will pass over all the space heater surfaces. We anticipate using this air heater and blower for drying out transformer cores on the floor under canvas, large motors; and in fact, anywhere where a steady current of hot air (about 90 degrees Cent.) is necessary."

High Tension Lighting Arresters

"We have built houses over our 80,000 volt lightning arresters to protect them from freezing and were somewhat puzzled as how to heat the buildings until we thought of your Space Heaters. So we placed three in each house and these keep the solution from freezing and keep the arresters in operative condition."

Protection of Underground Motor and Generator Against Precipitation of Moisture

"In several of our underground pumping stations the atmosphere is close to the dew point at all times. As the normal underground temperature is approximately 55 degrees Fahr., any slight change in ventilation in the winter frequently causes a considerable precipitation of moisture on everything in the pump station. In our two dampest pump stations we are using C-H Electric Space Heaters under the motor, there being a space of approximately three-quarters of an inch in height from the under surface of the motor frame to the top of the bed plate. This heater is in service at all times, and, when the motor is not running, it is covered with a box made of No. 22 gauge galvanized iron.

We are using a similar arrangement on some of our large underground motors. The C-H Space Heater is the only one we have with cross section small enough to go into the limited space under our centrifugal pump motors."

In Electrical Laboratory Work

"In electrical engineering it is often necessary to determine temperature coefficient and heating effects on certain apparatus. With four C-H Heaters fairly distributed degrees of heat are obtainable. Thus substantial apparatus is obtained for this purpose at a minimum of expense. Since they are compact and stand rough handling they lend themselves well for laboratory work."

Transformer Rooms, Repair Shop, Lavatories

"We use four Heaters in series on 440 volts, to heat our transformer rooms, repair shop, and lavatories. They make good heaters at a reasonable price."

Substation Heating

"The United Illuminating Co., for whom I work, uses Space Heaters to make work in their substations comfortable."

Power House and Office Heating

"For your information, we use quite a number of these Space Heaters for heating our power house, as well as our office uptown."

At the Gatun Hydro-Electric Station, Panama Canal

"Space Heaters are used at the Gatun Hydro-Electric Station, Panama Canal, in the generators whenever they are shut down, to maintain a temperature sufficient to prevent the insulation from absorbing moisture from the surrounding air. They are permanently mounted on the distance ring of the unit just under the armature winding, 10-500 watt units are used. The use of these heaters as above mentioned has proved very satisfactory."

Time Clock

"One of these Space Heaters has proven its merits in a Cincinnati Time Recording Clock which was exposed to cold and damp weather."

Drying Telephone Switchboards, And Load Testing

"I have used C-H Heaters successfully for drying out telephone switchboards. I find them very convenient also for providing artificial testing loads in blocks of 5 amperes."

Armature Test Work

"I have a good and wide range of use for your Space Heaters, in an armature test arrangement connected to a rheostat face. This also gives the best range of current for general tests that I have found yet."

Resistor Capacity For Armature Testing

"While in charge of a Motor Department, we had a large armature to rewind and trying to test it out found that our lamp banks did not have current capacity enough to give our Mils ammeter sufficient throw on the scales. So we rigged up six C-H Heaters in connection with one lamp bank and it did the trick O. K."

Temporary Resistor

"At Sea Breeze, N. Y., while with a Construction Co., we had to wire for an air compressor connected with water system and when the outfit came it had a 110 volt single phase 1 H. P. motor and we had wired for a 220 volt motor as our instruction called for. As they wanted to use the water system at once we used two of your Heaters as temporary resistance and the motor ran for about five weeks in this manner until a 220 volt motor was sent out from the manufacturer at which time we changed the motors and took out the heaters. It ran satisfactorily in every respect and the heaters were mounted direct to the wall with screws and on porcelain insulators with asbestos under them."

Emergency Resistors

"I have at various times had occasion to use C-H Space Heaters to my entire satisfaction I have used them both singly and in parallel for getting any desired value of current. Occasion often arises to use them in repairing broken down resistances and also for controlling the speed of motors. Their compact construction makes it possible to install them in emergency cases and also on permanent jobs and they have proven to be a great help to me."

Miscellaneous Applications in and About Electric Water Power Plants

"We have found C-H Electric Heaters very useful installed in the cast iron tubes which house the floats operating our Head and Tail Race Gauges. Due to the severe climate here these floats would be frozen fast at times if it were not for electric heaters installed along the sides of the casing, which keeps the temperature above freezing point." * * * *

"C-H Electric Space Heaters placed in front of headgates keep the ice from forming, thus allowing the gates to be raised or lowered at any time during the winter."

* * * *

"Space Heaters replace carbon lamps which we have been using in the past to keep the headgates at the intake of our electric power development at Chasm Falls, N. Y. from freezing up and the success we have had with the lamps has suggested the use of your Space Heaters for the same purpose." * * * *

"We also will place one or two of these heaters in the opening at the top of the air-vent leading to our penstock to keep ice from forming, so that there will be no danger of the pipe collapsing in case of an obstruction to the water at the racks."

* * * *

"We have eleven air relief valve houses along our two and a half miles of penstock in which we use C-H Space Heaters to keep the valves from freezing."

Attached to Washing Machines

"Attaching a C-H Electric Space Heater to my Laundryette electric washing machine keeps the water hot." * * * *

The new Booklet "Dictionary of Uses" C-H Electric Space Heaters" should be in your files.

The Cutler-Hammer Mfg. Co.

Works:
MILWAUKEE and NEW YORK

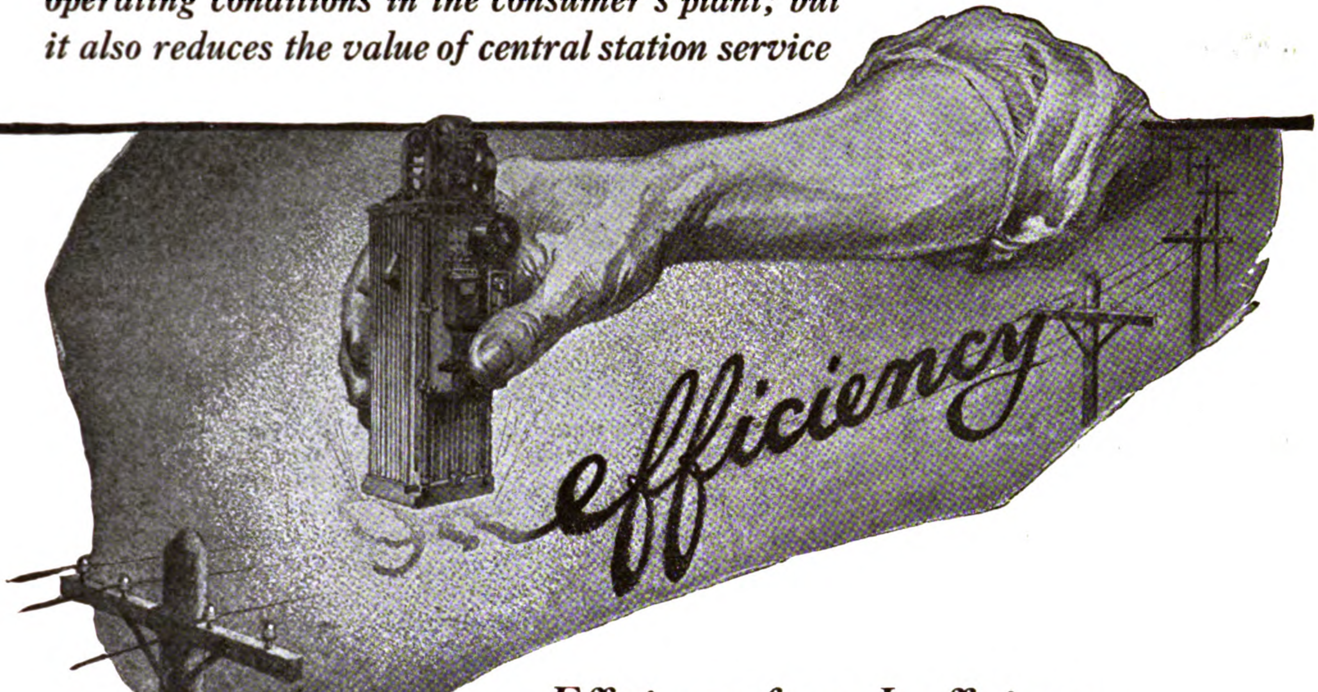
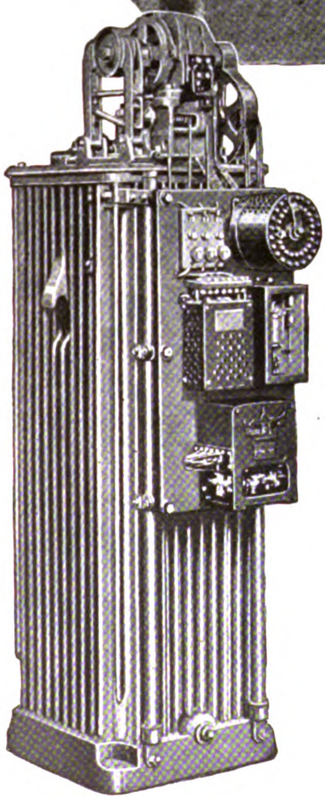
New York, Chicago, Boston, Philadelphia, Pittsburg, Cleveland, Cincinnati, Detroit, San Francisco, Los Angeles, Seattle, Birmingham.

"Two Feet of Electrical Heat"

If your Electrical Supply Jobber has no stock write to the Cutler-Hammer District Office nearest you for prompt attention.

Inefficient distribution because of poor voltage regulation not only affects operating conditions in the consumer's plant; but it also reduces the value of central station service





Efficiency from Inefficiency through G-E Induction Voltage Regulators

OF course, you know the size of your feeders and the size and location of transformers, but how much do you know about the voltage at the ends of your feeders, especially at times of peak load?

There is a G-E Induction Voltage Regulator for every class of service.

Call in our engineering specialist and let him show you how the added earning power of a regulator will soon pay for itself.

His services are yours for the asking.

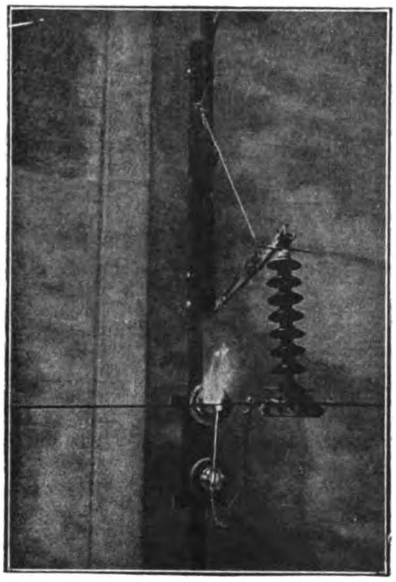
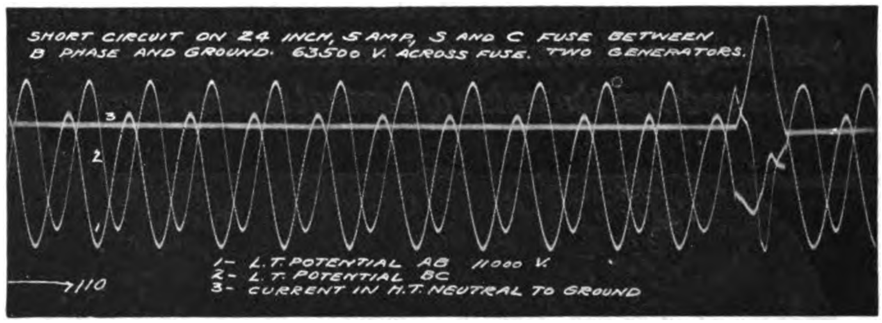
S&C HIGH POTENTIAL FUSES



S&C Fuse clearing 66,000 volt short circuit with two 9000Kw. generators in parallel.



Oscillogram record of test. The circuit was cleared in one-half cycle or 0.02 seconds. The 66,000 volt S&C Fuse was connected between one phase and neutral on a 110,000 volt circuit of a very large hydro electric station.

REMARKABLY EFFECTIVE

The accompanying illustration of a fuse blowing under unusually severe conditions clearly demonstrates the ease of operation, freedom from severe arcing, or other evidence of distress.

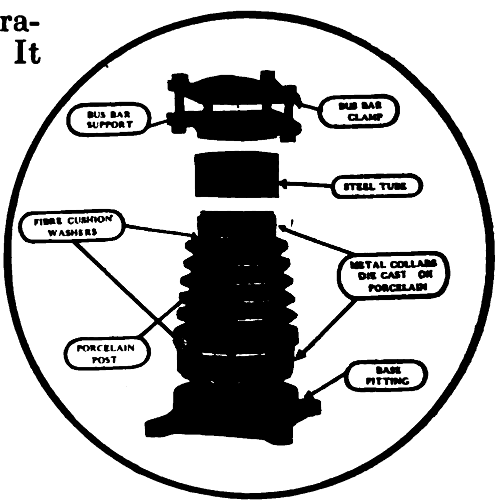
The oscillogram record of this test further emphasizes this remarkable performance. Write for further information concerning the application of S & C Fuses for protective purposes.

SCHWEITZER & CONRAD INC

4435 RAVENSWOOD AVENUE CHICAGO, ILLINOIS U.S.A.

REMEMBER "FRANKLIN" BY THESE THINGS—

EVERY device in the "FRANKLIN" line of generating station equipment is a safer thing to use. It has been designed for that definite purpose, and it is safer—for instance—



The "Franklin" Post Type Insulator is safer because the metal bushings are die cast directly on to the porcelain, then machined and threaded to receive the fittings. There is no cement to crumble, no clamps to cause spot pressure, no dirt pockets. It gives great strength and durability. ***It's safer.***

The "Franklin" Pothead is safer because two clamping members automatically bell out the lead sheath of the cable and eliminate all possible concentration of static strain. It makes a waterproof, solderless joint. It is very strong and very simple to install. ***It's safer.***

The "Franklin" Disconnecting Switch is safer because it combines the safer qualities of the "Franklin" Insulator with the "Franklin" Positive Lock. This lock makes a closed bridge across the blade at such an angle that resultant electric forces tend to hold it more tightly closed. Yet one pull of the hooksticks opens both lock and blade. It is very strong and sure. ***It's safer.***

These are just three features of the "FRANKLIN" line. Test them. Try them. Study them. Use them. See why it is we say—*"Install the 'FRANKLIN' and forget it."* Every "FRANKLIN" device has distinct refinements that make it better, surer and safer. Write for our bulletins.

MIDWEST TURBINES

High Duty Pumping Plants Require Midwest Turbines

High priced coal makes every pound of steam that can be saved a net profit against your operating cost. Where you need exhaust steam for feed water heaters, Midwest Engineers can design a turbine which will use the required amount of steam and save the surplus coal used where conditions are not balanced.

Where steam heat is needed you can use your Midwest Turbines as reducing valves to your heating system, thereby getting your heat at a minimum cost.

Midwest Turbines and Pumps have the combined qualities of extreme simplicity and highest economy.

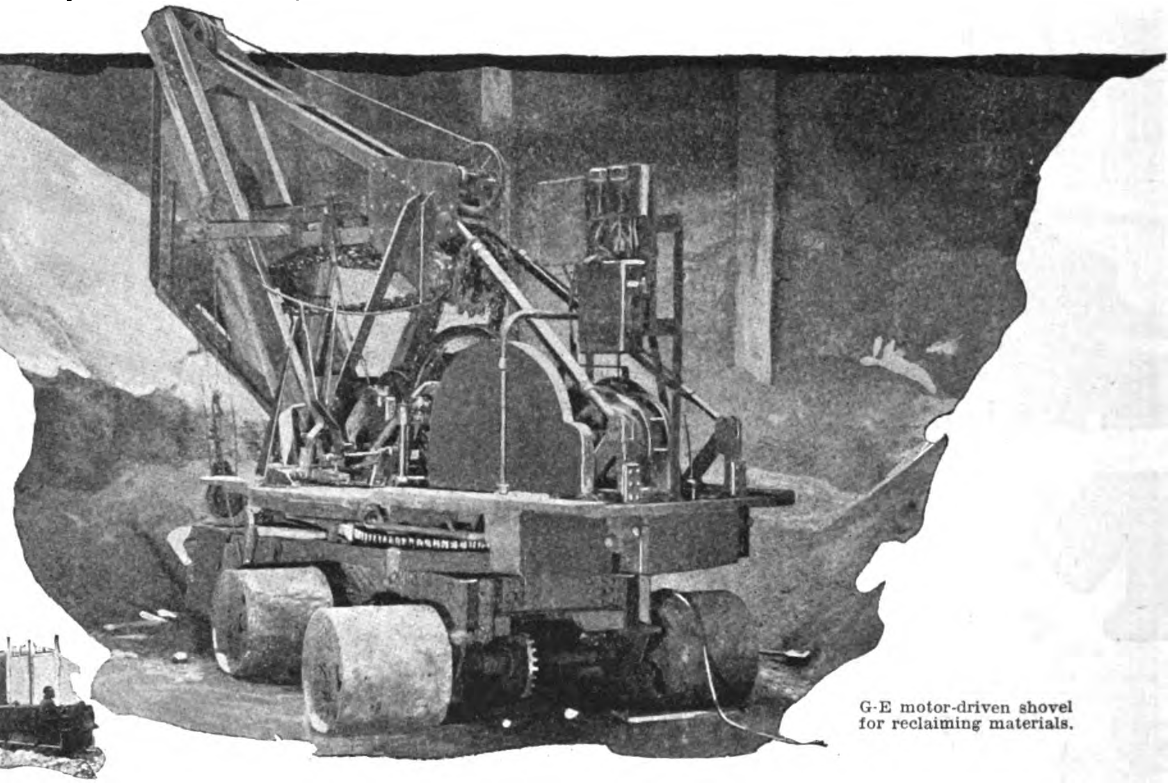
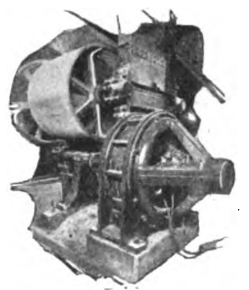
DEPENDABLE POWER

The future expansion of the chemical industries in America is largely dependent on the development of electrically operated machines for handling materials

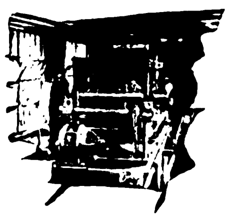


G-E motor-driven shovel for reclaiming materials.

G-E storage battery locomotive hauling salt cake.



G-E induction motor driving reclaiming conveyor.



G-E motor-driven mixing car in large glass works.

Specify Machines G-E Built or Equipped

Yesterday a few tons to be moved—today mountainous heaps. This is the new problem of material handling which the expanding chemical industry is solving *with electricity.* No other solution is so satisfactory.

Many plants, highly efficient in their strictly chemical functions, are achieving great economies by handling material with electrical equipment—good for 24 hours a day in spite of dust, fumes, temperature extremes and severe mechanical strains. The reliability of this modern electrical machinery is based on utmost skill in design and long manufacturing experience. G-E products have this substantial basis.

General Electric equipped machinery is giving satisfactory service in a wide variety of installations. G-E engineers are ready to co-operate with builders of material handling machinery and to help solve new problems this machinery must meet.

The G-E specialist in our nearest office is ready to work with you—ask him to call

℞ For Motors and Generators not up to par—

MORGANITE BRUSHES

OFTENTIMES motor troubles are due to inferior and unsuitable brushes. One sure way to eliminate such trouble is to equip motors with the right grade of *Morganite Brushes.*

The time and thought put into the selection of the most suitable grade of brush for any given set of conditions are amply justified by the results obtained.

Morganite

brushes are made in an infinite variety of shapes and sizes and in the following distinctive classes:

Standard Morganite Brushes
Hard Morganite Brushes
Copper Morganite Brushes
Morganite Carbon Brushes
Morganite Electro-Graphitic Brushes

Our research laboratories have rendered the most valuable help to the electrical profession. We will be glad to know *your* brush requirements and to recommend the proper *Morganite Brush* for any general or specific use.

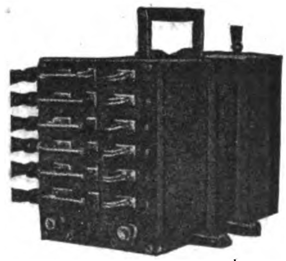
AMERICAN TRANSFORMERS

Industrial Transformers

Water Cooled Furnace Transformer.

With the tremendous increase in industrial activity there arise many process-development problems requiring special transformers for laboratory and experimental work.

The American Transformer Co. is not only well prepared to fill your special requirements with respect to laboratory transformers, but offers to study your transformer problems throughout the development of a process to the commercial stage.



Portable ½-kva. Laboratory Transformer 1 to 64 Volts in 1 Volt Steps

POWER FACTOR
AND
COST OF SERVICE

The rapidly increasing tendency toward such refinements in power contracts as will reflect accurately the various elements entering into cost of service demands a simple and unfailing means of measuring power factor.

Our *Phasing Transformers* and standard meter equipment meet all requirements.

THE STATES COMPANY

74 Francis Ave., Hartford, Conn.

TYPE 102

DECADE RESISTANCE BOXES

A practical resistance unit for laboratory use. The units are wound by the Ayrton-Perry method thus having a minimum of inductance and distributed capacitance. Adapted for use with direct or alternating current of any frequency, including radio.

Each dial has eleven points, thus making it a complete unit. The multiple contact brushes insure low and constant resistance. No plugs to work loose or become lost.

Made in seven sizes from two to four dials with total resistances of from 11 to 11,110 ohms.

Bulletin 201 E will be sent on request.

Electrical Testing Laboratories

Inspections—Tests—Research

Tests may be used by the purchaser for the following purposes:

(1) To determine the quality of competing samples.
This enables the purchase of the best quality for the money.

(2) To make sure that shipments comply with specifications.
This makes possible the assurance to the customer that shipments match buying samples.

(3) To furnish an impartial decision in case of disputes between purchaser and manufacturer.

Testing places the whole buying problem on a sound basis.

Transformer Engineers and Manufacturers

It's the labor that counts—

JOHNS-MANVILLE Fibre Conduit weighs one-fifth as much as tile duct. It is laid more quickly.

Trenches can follow grade changes and always be of minimum depth.

Pulling cables is a quick job owing to the smooth bore.

Yet, in addition, Johns-Manville Fibre Conduit actually costs less to buy than tile duct.

Can there be more convincing arguments than these for the use of a material that has the unequalled durability and protection value of Fibre Conduit?

Over 100,000 Industrial Users

The most conclusive proof of "Union" Fuse superiority lies in the fact that at the present time there are more than 100,000 industrial users scattered through every state in the country.

A canvass among a large percentage of our Distributors, Jobbers and Dealers shows that these 100,000 plants are *regular customers*, not casual buyers. When they require more fuses they demand "Union" because they know by experience that for reliability, strength, durability and low cost, "Union" Fuses are in a class by themselves.

If "Union" Fuses were not making good would this great army of users continue to buy them?

Built with scientific precision and tremendous strength to resist repeated blowouts, "Union" Renewable Fuses represent a real money-saving investment. Don't buy fuses of doubtful performance. Demand the "Union" (renewable or non-renewable type), the kind that makes good.

"Union" Fuses, both Renewable and Non-Renewable, for sale by all leading electrical jobbers and dealers. They are approved in the very highest degree by the National Board of Fire Underwriters. Free descriptive booklet sent on request

Chicago New York

"UNION"

RENEWABLE & NON-RENEWABLE FUSES

"Here is the *one* renewable Fuse that is fool-proof"

"It will definitely eliminate our dangerous short circuit explosions as well as the burning out of our expensive motors and equipment.

It is fool-proof. I have finally found the only renewable fuse that cannot be overloaded or improperly reloaded intentionally or unintentionally."

The element itself is sealed in a powder-packed renewable cartridge.

Only one renewable cartridge of the proper size and rating can be inserted at a time, due to its patented design.

NATIONAL RENEWABLE FUSES are positive and safe in their action—they will guard your electrical circuits accurately, dependably and economically.

Remember—

The NATIONAL RENEWABLE FUSE is the only Renewable Fuse that has been approved by ALL of the following Insurance Regulating Bodies:

Associated Factory Mutual Fire Insurance Companies
Hydro Electric Power Commission of Ontario, Canada
Millers' Mutual Fire Insurance Companies
Western Factory Insurance Association
Underwriters' Laboratories, Inc.
Mutual Fire Prevention Bureau
Factory Insurance Association

Made in Both 250 and 600 Volts up to and including 600 Amperes

Write today for full information and prices, and name of local distributor. Complete stock carried by jobbers and dealers everywhere.

If you have not received your free copy of "Correct Fuse Ratings for Motor Circuits," send for it today.

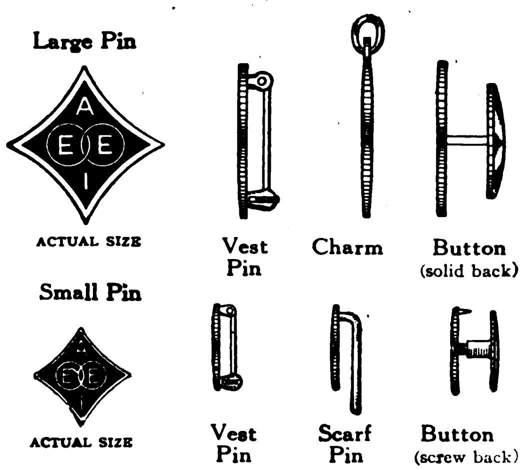
A. I. E. E. MEMBERSHIP BADGES

STYLES OF BADGES



PRICES OF BADGES

Size	Style Back	Price	Style No.
Large	Vest Pin	$4.50	1
Large	Charm	4.50	2
Large	Lapel Button (Solid Back)	6.00	3
Small	Vest Pin	3.00	4
Small	Scarf Pin	3.50	5
Small	Lapel Button (Plated Screw Back)	3.00	6

THE membership of the Institute is privileged to wear the official badge of the society in the various styles shown herein.

All the membership badges are of solid 14k gold, excepting the small size lapel button, the screw back of which is of plated gold. The enameled background is maroon for Associates and blue for Members, with letters and border in gold. The Fellow badge is the reverse in color of that provided for Members.

Upon transfer to the Member grade an Associate badge (large size only) can be reenameled blue at a cost of $1.00. The small badges and the large size Member badges cannot be reenameled; a credit of $.75 for a small badge and $1.00 for a large badge ($1.25 for large lapel button) will be allowed, however, upon the return of a badge to Institute Headquarters, to apply as part payment for a new badge. This credit is also allowed to those members who desire to exchange a large size badge for the smaller size.

Orders for badges should be accompanied by remittance and should indicate Badge Style Number (see price-list) desired.

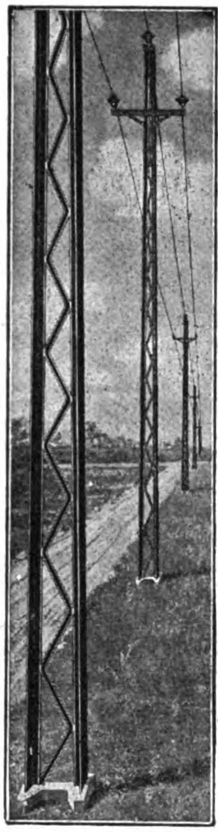
Bates Steel Pole Treatise



1921 Edition
(Free)

A new catalogue and engineering handbook of inestimable value to engineers and pole users of the world, containing information necessary to the economical construction of modern transmission lines, electric railways, street lighting systems, and outdoor substations.

The most complete and accurate steel pole handbook ever issued—an authority upon modern steel pole line construction.

PARTIAL LIST OF CONTENTS:

1. Compact accurate engineering tables of—
   a. Sags for all temperatures and spans of wires and cables.
   b. Conductor sizes required to transmit electric power.
   c. Transverse loads on wires for various wind velocities.
   d. Clearances necessary to determine the minimum length of pole.
   e. Physical properties of wires and cables.
   f. Formulae and example pole line problems.
2. Discussion of the engineering principles governing the design, selection and installation of all types of poles.
3. A complete analysis of the elements governing the selection of factors of safety, and a discussion of world-wide practice.
4. Comparison of Bates expanded one-piece steel poles with wood, fabricated steel, and tubular steel poles.
5. Method of manufacture of Bates expanded one-piece steel poles.
6. Superior features and properties of expanded one-piece steel poles.
7. Catalogue of poles, cross arms and fittings.

This treatise will be sent to anyone interested. Write today for your copy

FORMICA

For Every Insulating Purpose

Formica has a tensile and compressive strength averaging 20,000 lbs. per sq. in.—50% greater than hard fibre.

It is impervious to and absolutely insoluble in hot or cold water, live steam, oils and all ordinary solvents.

It will not warp, swell, shrink or otherwise deteriorate with age.

Formica on account of its moisture-proof qualities and high tensile and dielectric strength is indispensable to all manufacturers of high-grade electrical apparatus.

Write our nearest office for full information.

SHEETS TUBES RODS

S-S

SUPER-SEASONED FIBRE

THE "S-S" trademark stands for the highest quality in fibre.

A quality founded on the exclusive and exacting super-seasoning of 'S-S', Fibre to a toughness, hardness, and dielectric strength impossible to secure through any other process of manufacture.

Our Experimental Department is at your service in determining the adaptability of "S-S" Fibre for substitution of more expensive and unsatisfactory materials.

Send for our "S-S" Fibre Book, showing the wide range of usefulness of Super-Seasoned Fibre.

O-B MODERNIZED INSULATORS
The Price of Prominence
Everyone interested in transmission of power knows that O-B Insulators predominate in quantity.
There is a string attached to such popularity.
For if even a minute percentage of
MODERNIZED INSULATORS
should prove defective the results would be intolerable.
Instead, the searching impartial judgment of the law of averages has established the constant reliability of O-B Insulators.
A type for every place on the line or in the station.
The Ohio Brass Company
